**Giant viruses**

**Giant viruses**

J.M. Claverie<sup>1</sup>, C. Abergel<sup>1</sup>

<sup>1</sup>*Structural and Genomic Information Laboratory,  
Mediterranean Institute of Microbiology, Marseille, France*

More than a century ago, the notion of "virus" was introduced to designate infectious agents invisible to the light microscope and capable of passing through "sterilizing" filters. In addition to their extremely small size, most viruses studied over the years also exhibited minimal genomes and gene contents, almost entirely relying on cell-encoded functions to multiply, as expected from absolute intracellular parasites. Unexpectedly, the last ten years have seen the discovery of 4 different families of eukaryotic "giant viruses" exhibiting particles of cellular dimensions as well as gene contents overlapping in size with that of bacteria and some parasitic eukaryotes. Although all presently known giant viruses have been isolated using *Acanthamoeba* as laboratory host, related members are now starting to be found in other protozoa, such as marine picoplankton species the population of which they regulate. Representatives of two families of giant viruses have been revived from a layer of Siberian permafrost radiocarbon dated from 30.000 years ago, raising concern that pathogenic viruses from long past epidemics might also remain infectious and resurface in circumpolar regions as a consequence of global warming and industrial exploitations.

The unexpected abundance, ubiquity and diversity of giant viruses, as well as the alien nature of their gene contents deeply challenge conventional conceptions about the origin and evolution of all DNA viruses and raise the question of their evolutionary relationship with the 3 cellular domains forming today's Tree of Life, and possibly other long extinct cellular lineages.

It will conclude by discussing the nature of the epistemological barrier that led to the delayed discovery of these highly visible viruses, most of which were spotted 10 year before their viral nature was eventually recognized.

**FEMS-1062**  
**(Human) microbiome**

**(human) microbiome**

J.K. Jansson<sup>1</sup>

<sup>1</sup>*Biological Sciences, Pacific Northwest National Laboratory, Richland WA, USA*

The performance of the human microbiome is perturbed in unknown ways by a variety of factors including disease and diet. Here we aimed to determine the impact of inflammatory bowel disease (IBD) and a resistant starch diet on the gut microbiome community composition and functional potential by application of an array of omics technologies: 16S rRNA sequencing, metagenomics, metaproteomics and metabolomics. The first studies focused on a Swedish twin cohort and a longitudinal cohort for IBD. Specific bacterial species, proteins and metabolites correlated with different sub-phenotypes of the IBD; including a reduced amount of normal beneficial microbes as well as proteins involved in butyrate metabolism, suggesting potential biomarkers of IBD. For the dietary study, subjects transitioned from a baseline diet to one with low or high amounts of resistant starch. Specific bacteria, proteins and metabolites were shown to significantly vary in abundance when comparing baseline to the high resistant starch diet. Together these studies exemplify the use of omics to provide potential bioindicators of specific physiological states of importance to human health.

**Plant-fungal pathogens**

**Plant-fungal pathogens**

P.J.G.M. de Wit<sup>1</sup>

<sup>1</sup>*Plant Sciences Laboratory of Phytopathology, Wageningen University, Wageningen, Netherlands*

Fungi are notorious plant pathogens that cause serious diseases on natural vegetations and crop plants. The majority of plants, however, is not infected by fungal pathogens as they recognize pathogen-associated molecular patterns (PAMPs) like chitin or glucans by pattern recognition receptors that mediate PAMP-triggered immunity (PTI), a basal defense response effective against potential fungal pathogens. Successful fungal plant pathogens secrete effectors to suppress PTI and alter host plant physiology enabling them to infect plants. In turn, plants have evolved immune receptors that recognize effectors resulting in effector-triggered immunity (ETI) including the hypersensitive response, effective against biotrophic fungal plant pathogens that require living cells to feed on. Other fungal pathogens are hemi-biotrophic, which start infection as a biotroph, but after having colonized the host tissue can also feed on death tissue. Necrotrophic fungal pathogens kill host tissue before they start to feed on it. Co-evolution between fungal pathogens and their hosts had led to the development of numerous effectors in fungal plant pathogens and corresponding resistance proteins in host plants, which has generated an arms race genetically described by the gene-for-gene concept. Resistance genes encoding resistance proteins have now been cloned and are successfully transferred to crop plants by classical breeding or as transgenes stapled into one plant cultivar.

**FEMS-0682**

**Resistome**

**Ranking risks in resistomes. The intrinsic resistome**

J.L. Martinez<sup>1</sup>

<sup>1</sup>*Biotechnología Microbiana, Centro Nacional de Biotecnología. CSIC, Madrid, Spain*

Before the antibiotic era, bacterial pathogens were by definition susceptible to the antibiotics that pharmaceutical companies have developed to fight infections. Nevertheless, soon after the introduction of antibiotics for therapy, resistant isolates emerge and spread among the population. Resistance can be acquired either because of mutations or by acquiring resistance genes from a donor strain. Since pathogens were susceptible, resistance genes should come from non pathogens and, most likely from environmental microorganisms. Indeed, the analysis of metagenomes from very different ecosystems has shown that antibiotic resistance genes are ubiquitously found in any place in Earth. These genes (the resistome) can be transferred to human pathogens, then constituting a risk for human health. However, if all ecosystems contain resistance genes, all of them will be risky, which is the same as saying that no one has a relevant differential risk. In the presentation the possibility of ranking risk of resistomes will be discussed. The ranking is based in the likelihood that the finding of a specific gene in a given ecosystem constitutes a real risk for human health. One of the relevant aspects to take into consideration is whether those genes belong to the transferrable resistome (the mobilome) or are just a part to the set of elements that contribute to the characteristic phenotype of susceptibility to antimicrobials of a given microorganisms (its intrinsic resistome). Current information on the elements forming part of the intrinsic resistome will be discussed in the presentation.

**Resistome**

**Delineating the dissemination of antibiotic resistance genes within microbial communities**

M. Sommer<sup>1</sup>

<sup>1</sup>*Center for Biosustainability, Technical University of Denmark, Hørsholm, Denmark*

Antibiotic resistance is a growing public health concern that negatively impacts treatment outcomes of most infections. The issue is projected to grow substantially in the coming decades and new approaches are needed to curb the spread of resistance. Notably, resistance evolves through a complex interplay between residents of most microbial communities and organisms causing disease. In spite of significant efforts using a variety of experimental and computational approaches our understanding of the dissemination of resistance genes is still limited. To institute preventative regulations on key environments harboring microbial communities that influence resistance gene dissemination general and unbiased approaches are necessary. Yet, to date our ability to assess the impact of specific microbial communities on the dissemination of antibiotic resistance is inadequate. Recent improvements in experimental and computational approaches aimed at addressing this overall goal are discussed with a focus on key environments believed to influence resistance gene dissemination.

**COMPARATIVE GENOMICS TO INFER THE ANTIBIOTIC RESISTANCE  
MOBILOME IN CLONALLY RELATED AND UNRELATED STRAINS**

R. Willems<sup>1</sup>

<sup>1</sup>*Medical Microbiology, University Medical Center Utrecht, Utrecht, Netherlands*

The introduction of antibiotics revolutionized human medicine and agricultural industry, but their success has created a public health threat caused by antibiotic-resistance (ABR). Indisputably, human use of antibiotic has contributed to the expansions of ABR. At the same time it is becoming increasingly clear that antibiotic use in animal husbandry has also created a large reservoir of ABR with increasing risk of spill over of ABR from animals to humans. Whole genome sequencing (WGS) has revolutionizing research into transmission of ABR by providing the optimal resolution to infer epidemiological linkage of multidrug resistant isolates and their resistance genes and plasmids. However, frequently used WGS technologies rely on the generation of sequences with short-read length resulting in many contigs of assembled reads without easy assorting contigs to plasmids and the main chromosome. We used a novel algorithm called PLACNET that identifies plasmid contigs in WGS projects to study genetic relatedness of ESBL-genes containing plasmids from animal and human origin. Plasmid reconstructions, validated by long-read DNA sequencing, indicated that genetically unrelated human isolates shared virtually identical plasmids with animal isolates.

Another potential drawback of WGS for studying transmission of ABR is the lack of a standardized and expandable classification scheme since most WGS-based analyses rely on SNP detection from reads mapped to reference genomes that are often distinct for different epidemiological studies. This limitation may be overcome by using a gene-by-gene comparison approach just like classical MLST but with an important extension of the numbers of analysed genes from seven to several hundreds/thousands. We developed an extended, core genome MLST scheme and showed its value in determining the clonal relatedness of multi-resistant *Enterococcus faecium* from hospital outbreaks in three different countries.

**Resistome**

**Networks of Exchanging Antibiotic Resistance in Human and Environmental Microbiota**

G. Dantas<sup>1</sup>

<sup>1</sup>*Department of Pathology and Immunology,  
Washington University School of Medicine, St Louis, USA*

While the most acute effects of increasing antibiotic resistance in pathogens are observed in clinical settings, it is becoming increasingly clear that the evolution and transmission dynamics of resistance gene dissemination is an ecological problem. Indeed, steady use and abuse of antibiotics over the past century in food animals, humans, and the environment has provided substantial selective pressure for enrichment of resistance genotypes in each of their associated microbiomes. An over-reliance on culture-based methods, the standard in the study of clinical resistance, has vastly underestimated these reservoirs of resistance genes (or 'resistomes'). To address this issue, we have recently developed high-throughput metagenomic functional selections, aided by next-generation sequencing, to characterize resistomes encoded by the microbiota of healthy human adults and children as well as diverse soils. Hundreds of resistance genes we identify from specific taxa in these different microbial communities are identical to resistance genes found in major human pathogens, indicating recent genetic exchange between these microbes. We also find thousands of functionally validated resistance genes which are genetically novel, but flanked by genes involved in horizontal gene transfer, including transposases and integrases. Together, these findings highlight the substantial antibiotic resistome encoded by microbes from diverse environments, which is available for exchange with pathogens, with the potential to severely exacerbate the problems with clinical resistance.

#### **Protein secretion and secreted proteins in *Neisseria meningitidis***

J. Tommassen<sup>1</sup>, J. Arenas<sup>1</sup>

<sup>1</sup>*Molecular Microbiology, Utrecht University, Utrecht, Netherlands*

*Neisseria meningitidis* is a strictly human pathogen that colonizes the nasopharynx as a commensal but occasionally crosses the epithelial barriers to cause sepsis and/or meningitis. Proteins secreted by this Gram-negative diplococcus are considered to be important for colonization and/or infection. Of six protein secretion systems widely disseminated among Gram-negative bacteria, only two are present in *N. meningitidis*, i.e. type I and type V, the latter being subdivided in autotransporters and two-partner secretion (TPS) systems.

We are investigating the functions of type V secreted proteins and found that many of them are involved in interbacterial interactions. Neisserial IgA protease was the first autotransporter ever described. Besides its protease domain, also a ~40-kDa polypeptide of unknown function, the  $\alpha$ -peptide, is transported to the bacterial cell surface. Our results demonstrate that this positively charged  $\alpha$ -peptide and a cell-surface-exposed lipoprotein, the neisserial heparin-binding antigen (NHBA), are involved in biofilm formation by binding extracellular DNA, an important matrix component of meningococcal biofilms. Another autotransporter, the protease NalP, inhibits biofilm formation by cleaving the  $\alpha$ -peptide of IgA protease and NHBA from the cell surface. Yet another autotransporter, designated AutA, is only expressed in a limited number of meningococcal isolates. Its expression causes bacterial autoaggregation and influences the architecture of the biofilms formed.

The substrates of the meningococcal TPS systems are large proteins. These proteins were found to contain a small toxic domain at their C-terminus that inhibits the growth of related bacteria. Similar toxic domains were found at the C-terminus of another family of proteins, MafB. MafB proteins are transported to the cell surface via a protein, MafA, representing a novel protein secretion system. Like the TPS system, the MAF system is involved in interbacterial competition.

**How a surface-exposed lipoprotein functions as an envelope stress sensor in enterobacteria**

*S.H. Cho<sup>1</sup>, J. Szewczyk<sup>1</sup>, C. Pesavento<sup>2</sup>, A. Typas<sup>2</sup>, J.F. Collet<sup>1</sup>*

*<sup>1</sup>de Duve Institute, Université catholique de Louvain, Brussels, Belgium*

*<sup>2</sup>Genome Biology, EMBL, Heidelberg, Germany*

### **Background**

The cell envelope protects bacteria from their surroundings. Breaches in its integrity or defects in its assembly are sensed by signal transduction systems, allowing cells to rapidly adjust. The Rcs phosphorelay responds to outer membrane (OM)- and peptidoglycan-related stress in enterobacteria. An OM lipoprotein, RcsF, is required for sensing and transducing the stress signals to downstream components in yet unidentified manners.

### **Objectives**

We set out to discover how RcsF detects stress and activates the Rcs signalling cascade.

### **Methods**

We used a combination of methods, including site-specific photo-crosslinking, co-immunoprecipitation and fluorescence microscopy.

### **Conclusions**

We found that RcsF interacts with BamA, the major component of the OM beta-barrel assembly machinery. BamA funnels RcsF to the beta-barrel OmpA, allowing RcsF to reach the cell surface in an unresponsive-to-stress conformation. This spatially separates RcsF from the inner membrane-located IgaA, which we show is the next component of the cascade. Stress conditions prevent RcsF from interacting with BamA, allowing it to reach IgaA. Thereby the BamA-RcsF interaction acts as a checkpoint for lipoprotein transport to the cell surface, which we propose is mediated by BamA itself.

### **Pathogenicity and cell surface**

#### **Adhesion, invasion, evasion. The many functions of surface proteins of *Staphylococcus aureus***

T. Foster<sup>1</sup>

<sup>1</sup>*Microbiology, Trinity College Dublin, Dublin, Ireland*

*Staphylococcus aureus* colonizes the moist squamous epithelium of the nasal cavity of about 20% of the population where it resides as a harmless commensal. It can cause infections ranging from superficial skin and soft tissue infections to those that are invasive and seriously life threatening. The surface of *S. aureus* is decorated with up to 24 cell wall anchored (CWA) proteins that are covalently linked to peptidoglycan by sortase. CWA proteins perform a variety of functions *viz* adhesion to host cells and tissue, evasion of innate and adaptive immune responses, invasion of host cells, acquisition of iron from haemoglobin, biofilm formation and stimulating inflammation. They can be classified into six groups based on structural and functional characteristics. The largest class are called microbial surface components recognising adhesive matrix molecules (MSCRAMMS) which have at their N terminus an A domain containing two adjacent subdomains each comprising IgG-like folds. MSCRAMMS bind to short peptide sequences within host proteins by the dock latch lock mechanism. Clumping factor A is the archetypal MSCRAMM which binds to the C-terminus of the gamma-chain of fibrinogen. The N-terminal A domains of MSCRAMMS are displayed on the cell surface aided by unfolded flexible stalks. In the case of ClfA and many other MSCRAMMS the stalk comprises serine-aspartate dipeptide repeats. In fibronectin binding proteins the linker for the A domain comprises fibronectin binding repeats. Several CWA proteins are being tested as components of vaccines aimed at reducing *S. aureus* infections

**Pathogenicity and cell surface**

**Role of the ESX-5 protein secretion system in functioning of the mycobacterial cell envelope and in virulence**

W. Bitter<sup>1</sup>, E.N.G. Houben<sup>2</sup>

<sup>1</sup>Medical Microbiology, VU university/VU university medical center, Amsterdam, Netherlands

<sup>2</sup>Medical Microbiology, VU university, Amsterdam, Netherlands

Mycobacteria use type VII secretion (T7S) systems to secrete proteins across their complex cell envelope. Pathogenic mycobacteria, such as the notorious pathogen *Mycobacterium tuberculosis*, have up to five of these secretion systems, named ESX-1 to ESX-5. At least three of these secretion systems (ESX-1, ESX-3 and ESX-5) are essential for mycobacterial virulence and/or viability. Elucidating T7S is therefore essential to understand the success of *M. tuberculosis* and other pathogenic mycobacteria as pathogens, and could be instrumental to identify novel targets for drug- and vaccine-development. Recently, significant progress has been achieved in the identification of T7S substrates. We have identified a general motif (YxxxD/E) that is required for secretion. Surprisingly, this motif does not determine system specificity. Secretion of substrates is also dependent on the function of dedicated chaperones. We are currently determining whether these chaperones are involved in system specificity. In addition, a start has been made with unraveling the mechanism of secretion and the structural analysis of the different subunits. We have identified the membrane translocation complex of both the ESX-1 and ESX-5 system. Finally, one of the T7S systems, ESX-5, is only present in slow-growing mycobacterial species and is responsible for the secretion of dozens of substrates. We have recently shown that ESX-5 substrates play a role both in virulence and in nutrient uptake. The latter characteristics could be linked to its exclusive presence in slow-growing mycobacteria.

**Yeast biotechnology Offered by FEMS Yeast Research**

**Engineering central metabolism in yeast for production of fuels and chemicals**

J.T. Pronk<sup>1</sup>

<sup>1</sup>*Biotechnology, Delft University of Technology, Delft, Netherlands*

*Saccharomyces cerevisiae* is a robust industrial micro-organism and a popular platform for metabolic engineering. Breath-taking advances in synthetic biology have greatly increased the pace and ease with which biochemical pathways towards non-native compounds can be expressed in this yeast. For environmentally and economically sustainable production of such compounds, it is essential that product yields on (sugar) substrate are as close to their thermodynamic maxima as possible. This not only requires 'tuning' of the non-native product pathways, but also optimization of their interaction with central metabolism, for example for the generation of product precursors and for redox balancing. While central metabolism of *S. cerevisiae* and its regulation have been shaped in aeons of natural evolution to improve competitiveness in natural environments, several key aspects of its redox and energy metabolism are clearly suboptimal for industrial application. In this presentation, I will discuss novel metabolic engineering strategies to address these limitations and, thereby, enable improved yields of existing and novel products of engineered *S. cerevisiae* strains.

## FEMS-0645

### Yeast biotechnology Offered by FEMS Yeast Research

#### Coordination of yeast metabolism through phosphorylation

U. Sauer<sup>1</sup>

<sup>1</sup>*Institute of Molecular Systems Biology, ETH Zurich, Zurich, Switzerland*

While our knowledge on the topology of regulation network steadily increases, we understand much less about the functionality of individual regulation events and their quantitative relevance for controlling a given biological function and eventually a phenotype. Focussing on metabolism, we ask which mechanisms *Saccharomyces cerevisiae* employs to make decisions on the use of different pathways. Although obviously important, transcriptional regulation does not appear to be the major mechanism to control the activity of metabolic pathways in bacteria and yeasts (1). By combining quantitative proteomics, P-proteomics and flux measurements, we instead demonstrated in a pilot study that enzyme phosphorylation, in contrast to transcriptional regulation, frequently contributes to the in vivo control of pathway fluxes in bakers yeast (2). To more broadly investigate the role of phosphorylation in controlling enzyme activity, and thus pathway fluxes, we performed large-scale metabolomics on 118 kinase and phosphate deletion mutants. Combining the metabolome with P-proteomic data, we predicted functional phosphorylation for about 50 metabolic enzymes (3). Different from bacteria, the yeast kinase network is rather interconnected with often multiple kinases acting on a given enzyme, a redundancy that in many cases might obscure functionality assessment. Here I will discuss how we tackle the problem of functionality by two approaches: i) integration of dynamic metabolomics and P-proteomics data, focussing on TOR signalling, and ii) large-scale point mutations in P-enzymes that either mimic permanent phosphorylation (serine to glutamate) or prevent phosphorylation at a given site entirely (serine to alanine).

#### **Quantitative genetics of industrial and new yeast hybrids**

E.J. Louis<sup>1</sup>

<sup>1</sup>*Centre for Genetic Architecture of Complex Traits, University of Leicester, Leicester, United Kingdom*

Many yeasts used in industrial fermentations are not pure species but hybrids between 2 or more species. Their advantage is that they can combine useful properties from each of the parental species. The disadvantage for strain improvement is that these hybrids are sterile and therefore not amenable to genetic analysis. Complex trait analysis in these is virtually impossible due to this sterility. The most famous yeast hybrid is the lager yeast, *S. carlsbergensis*, also known as *S. pastorianus*, which actually arose from at least two independent hybridization events between *S. cerevisiae* and another *Saccharomyces* species. Genetic studies and strain improvement has generally been limited to single gene mutations and analysis of rare spore progeny. The recent discovery of the second parental species, *S. eubayanus*, has provided the opportunity to create new hybrids using diverse parental strains in order to enhance genetic analysis. These new hybrids still suffer from the problem of sterility however. There are other hybrids used in industry such as the *S. cerevisiae* by *S. kudriavzevii* hybrids used in wine fermentation. These are less well characterized than the lager strains but share many of the features, such as colder fermentation temperatures, and issues, such as sterility and genome stability. There are also many other hybrids isolated from nature that may or may not have industrial uses. We have recently utilized a tetraploid intermediate strategy to overcome the sterility of hybrids, which allows us to both genetically study existing hybrids as well as create new hybrids such that quantitative genetic analysis can be done. We have successfully restored fertility in a wine hybrid and are exploring the industrial potential of new hybrids, incorporating all the extant species.

### **Yeast biotechnology Offered by FEMS Yeast Research**

#### **Lignocellulosic bioethanol – from laboratory proof-of-concept to full scale plant**

L. Raamsdonk<sup>1</sup>, *H. de Bruijn*<sup>1</sup>, *P. Klaassen*<sup>1</sup>

<sup>1</sup>*Biotechnology Center, DSM, Delft, Netherlands*

Lignocellulosic feedstocks are considered to be of great economic and environmental significance for sustainable production of valuable fermentation products. For cost-effective and efficient industrial processes, complete and fast fermentation of all biomass sugars is a prerequisite. In this respect, the main challenge emerging from the use of lignocellulosic feedstocks for ethanol production by *Saccharomyces cerevisiae* is the efficient fermentation of the pentose sugars xylose and arabinose, as these sugars cannot be utilized by natural *S. cerevisiae* strains. Another significant challenge is the inevitable presence of inhibitors, such as furfural and acetic acid, which are formed during pretreatment and hydrolysis of the feedstocks and severely inhibit yeast growth and product formation.

DSM has developed advanced yeast strains by introducing heterologous pathways into robust *S. cerevisiae* hosts which resulted in the ability to ferment xylose and arabinose in lignocellulosic hydrolysates. Subsequently, by the application of evolutionary engineering the total time required to ferment hexoses and pentoses in lignocellulosic sugar mixtures was significantly reduced.

In order to take these developments to the next level, a toolbox for the new generation of advanced yeast strains is in development, in which the main challenges are further addressed by accelerating pentose fermentation through engineered pentose transport, as well as converting lignocellulosic inhibitors and biorefinery waste streams into additional ethanol. A roadmap to implementation of commercial strains in a full scale plant will be presented.

**Plant microbe interactions Offered by FEMS Microbiology Ecology**

**The phyllosphere microbiota: responses to and impacts on plants**

J.A. Vorholt<sup>1</sup>

<sup>1</sup>*Institute of Microbiology, ETH Zurich, Zurich, Switzerland*

The aerial parts of the plants, which are dominated by leaves, represent one of the largest terrestrial habitats for microorganisms. This habitat, called the phyllosphere, is occupied by a diverse community of microorganisms, which is important for plant health and growth. Most of the phyllosphere inhabitants are not well investigated; however, there is a growing interest to study commensal bacteria to elucidate their interactions with the plants, among each other and to learn how they withstand the hostile conditions of their habitat. A predominance of Proteobacteria, Actinobacteria and Bacteroidetes living in the phyllosphere of numerous plants has been revealed, while metagenomics and metaproteomics approaches gave insights into the general bacterial adaptation strategies to the phyllosphere. Complementary to these cultivation-independent approaches we established a comprehensive strain collection which covers a broad diversity of strains colonizing the model plant *Arabidopsis thaliana*. Targeted studies with model strains allowed us to identify metabolic traits important for plant colonization and to uncover a novel bacterial regulatory system essential for plant colonization which is responsible for the general stress response in Alphaproteobacteria. The establishment of a gnotobiotic system led to the identification of plant probiotic effects of commensal bacteria and candidate genes for plant protection against bacterial pathogens. Moreover, the experimental system paired with synthetic bacterial communities helped identifying plant genes involved in shaping the bacterial community structure.

Vienna University of Natural Resources and Life Sciences, Vienna, Austria

Metalliferous plants including (hyper)accumulators with tissues containing extremely high trace elements (TE) concentrations are associated with complex microbiomes, which are likely to be important for plant growth under such adverse conditions. Our studies addressed the ecology and microbial community behavior under different conditions as well as the role of plant-associated bacteria for the TE mobilization / availability and plant uptake.

We analyzed microbiomes associated with Zn-accumulating plant *Salix* species, which are applied for phytoextraction applications. Plants were associated with complex rhizosphere microbiomes, which correlated with the plant genotype and which were particularly rich in *Actinobacteria*. Bacteria isolated from Zn accumulating *S. caprea* showed highly different effects on TE mobilization. Several strains decreased bioavailability, whereas others, particularly *Actinobacteria* such as *Microbacterium* spp. strains, increased bioavailability. The mechanism of TE mobilization is poorly understood, however, we hypothesize that microbial secondary metabolites (such as siderophores) are involved in the mobilization process. We therefore have analyzed the genomes and metabolomes of Zn/Cd mobilizing actinobacterial strains to further elucidate the mechanisms involved in TE mobilization and plant uptake.

**FEMS-1021****Plant microbe interactions Offered by FEMS Microbiology Ecology****Back to the roots: microbiology and chemistry at the root-soil interface**

J. Raaijmakers<sup>1</sup>

<sup>1</sup>*Microbial Ecology, Netherlands Institute of Ecology, Wageningen, Netherlands*

**Back to the Roots: microbiology and chemistry at the root-soil interface**

Plant roots are colonized by an astounding number of (micro)organisms that can reach cell densities much greater than the number of plant cells. Many studies have shown that members of the rhizosphere microbiome can have profound effects on seed germination, seedling vigour, plant growth and development, nutrition and tolerance to pests, diseases and abiotic stress. For the vast majority of rhizosphere microorganisms, however, there is limited knowledge on the mechanisms involved in modulation of plant growth and plant health. Here, new results are presented on how rhizosphere bacteria and fungi impact on root architecture, root growth and plant tolerance to infections by soil-borne pathogens. For the rhizosphere bacteria, results showed that representatives of the  $\gamma$ -Proteobacteria protect plants from pathogen infection by the production of chlorinated peptides and alter root architecture and plant growth via modulation of the plants' sulfur metabolism. For the fungi-plant interactions, our results showed that specific soil-borne pathogenic fungi induce changes in root architecture and plant growth via volatile organic compounds. An overview will be given on the wealth of yet unknown functions and metabolic potential of the rhizosphere microbiome.

**Plant-fungal communication during arbuscular mycorrhizal symbiosis**

N. Requena<sup>1</sup>

<sup>1</sup>*Molecular Phytopathology, Karlsruhe Institute of Technology, Karlsruhe, Germany*

Fungi from the Phylum Glomeromycota establish one of the most ancient associations with plant roots helping plants to thrive and survive under conditions of mineral deprivation. These fungi are particularly good at improving plant phosphate nutrition while in return, plants provide fungi with carbohydrates. This mutualistic symbiosis is characterized by the formation of fungal specialized structures in the cortex, arbuscules, key to the nutrient exchange and giving name to the association: arbuscular mycorrhizal (AM) symbiosis. AM fungi, like all biotrophic fungi, are committed to keep plant defenses at bay and prevent the mutualistic association to become parasitic. It is only recently that the mechanisms of how AM fungi overcome the surveillance system of the plant and manipulate their metabolism are starting to be understood. In general AM fungi use at least three mechanisms to achieve that: i) avoiding being recognized; ii) suppressing defense responses elicited after recognition iii) using a specific dialogue that allows manipulation of the plant cell program. We were first to show that similar to pathogenic microorganisms, AM fungi do have and are able to deliver effector proteins to the plant to counteract MAMP-triggered immune responses (Kloppholz et al., 2011). With the recent outcome of the first genome of an AM fungus, the effector repertoire is starting to be envisaged, and the presence of LysM containing proteins, Crinkler-like effectors and secreted proteins with NLS and DNA modification motifs points out that the similarities with pathogenic fungi are likely to be more than previously anticipated. The aim of our work is to investigate how plant roots and arbuscular mycorrhizal fungi (AMF) perceive signals from each other and establish the molecular dialogue that permits a long-lived and harmonious symbiosis.

**Horizontal gene transfer, evolution**

**Horizontal gene transfer, antibiotics and stress response connections**

D. Mazel<sup>1</sup>

<sup>1</sup>*Unité Plasticité du Genome Bacterien, Institut Pasteur, Paris, France*

We have reported direct connections between the SOS response activation and HGT mechanisms such as conjugation and natural transformation, but also with gene capture in integrons. We also found that most antibiotics at sub-inhibitory concentrations induce the SOS response in *Vibrio cholerae*, and in other Gram-negative pathogens such as *Klebsiella pneumoniae*. This coupling enhances the potential for cassette swapping and capture in cells undergoing stress, while freezing the cassette arrangement in steady environments, but it also favors any mechanisms leading to resistance development through mutation. We have now undertaken the characterization of the different partners and pathways that are involved in these connections, in order to better understand these physiological responses and propose innovative strategies against the rise of resistance.

**FEMS-2871**

**Horizontal gene transfer, evolution**

**Horizontal gene transfer, microbial evolution and host adaptation**

C.J. Dorman<sup>1</sup>

<sup>1</sup>*Microbiology, Trinity College Dublin, Dublin, Ireland*

Gram-negative bacterial cells show copious evidence of evolution through the horizontal acquisition of novel genetic sequences with a high A+T content. In *Salmonella enterica* serovar Typhimurium, the majority of the main virulence genes fit this profile. These genes allow the bacterium to gain access to privileged sites in the host, such as the interior of epithelial cells, or to avoid being killed by components of the host defences such as macrophage. Understanding how such horizontally acquired genes are integrated into the regulatory regime of the bacterium presents a major challenge. We will provide evidence that in the case of *S. Typhimurium* regulatory integration has been achieved through combining horizontally acquired regulatory genes with regulators encoded by the ancestral genome with both operating on the virulence genes through a mechanism that exploits the special structural characteristics of A+T-rich B-DNA.

**Phylogenomic transduction networks reveal genetic barriers for phage-mediated lateral gene transfer**

T. Dagan<sup>1</sup>

<sup>1</sup>*Institute of General Microbiology, Christian-Albrechts University of Kiel, Kiel, Germany*

Viruses that infect bacteria – termed phages – are recognized vectors of lateral gene transfer between microbial cells. Bacteria and their parasitic phages are co-evolving in a constant arms race, yet their interaction may include also mutualistic aspects. The beneficial contribution of phage-mediated gene transfer to the host fitness has been documented in diverse species and environments. Here we study the contribution of phage-mediated gene transfer to the lateral component of microbial evolution using phylogenomic transduction networks. The networks are composed of donors, phages, and recipients that are connected by 23,014 lateral gene transfer events reconstructed from genomic data. Large-scale structural differences among the stable and transient sub-networks reveal the differential contribution of temperate and lytic phage-bacteria interactions to transduction dynamics in Nature. Our evolutionary reconstruction reveals high phage-host specificity in stable interactions, while transient interactions may occur with multiple hosts. Edge weight distribution in the network suggests that gene uptake from transient hosts into the phage genome typically includes a single gene, while gene transfer into stable hosts usually comprises several genes. Yet, transient interactions constitute an important contribution to the global network structure by connecting among clusters of stable hosts. Self-donor recipients constitute a significant portion of the network (21%), implicating transduction as an important gene duplication mechanism during microbial evolution. Furthermore, donors and recipients that have a similar genome sequence and similar codon-usage are more highly connected by transduction events than the expected by chance. This indicates that donor-recipient whole genome similarity is an important factor that shapes the transduction network connectivity pattern. Our results demonstrate the implication of phage-bacteria co-evolution to phage-mediated gene transfer during microbial evolution.

<sup>3</sup>CNRS, Institut Pasteur, Paris, France

Horizontal gene transfer (HGT) is an important mode of adaptation and diversification of prokaryotes and eukaryotes and a major event underlying the emergence of bacterial pathogens and mutualists. Yet it remains unclear how complex phenotypic traits such as the ability to fix nitrogen with legumes have successfully spread over large phylogenetic distances.

To get an insight into the evolutionary mechanisms that facilitated rhizobium diversification, we experimentally replayed the evolution of rhizobia. Following introduction of the symbiotic plasmid of *Cupriavidus taiwanensis*, the *Mimosa* symbiont, into pathogenic *Ralstonia solanacearum* we challenged transconjugants to become *Mimosa* symbionts through serial plant-bacteria co-cultures.

Using whole genome sequencing we showed that co-transfer of *imuABC* error-prone DNA polymerase genes with key symbiotic genes accelerates the evolution of a soil bacterium into a legume symbiont. We demonstrate that a mutagenesis *imuABC* cassette encoded on the *C. taiwanensis* symbiotic plasmid triggered a transient hypermutability stage in *R. solanacearum* transconjugants that occurred before the cells entered the plant. The generated burst in genetic diversity accelerated symbiotic adaptation of the recipient genome under plant selection pressure, presumably by improving the exploration of the fitness landscape. Finally, we show that plasmid *imuABC* cassettes are over-represented in rhizobial lineages harboring symbiotic plasmids. Our findings shed light on a mechanism that may have facilitated the dissemination of symbiotic competency among  $\alpha$ - and  $\beta$ -proteobacteria *in natura* and provide evidence for the positive role of environment-induced mutagenesis in the acquisition of a complex lifestyle trait.

### High throughput screening technologies

#### Nano-liter reactor technology for whole cell biocatalyst optimization and discovery

M. Held<sup>1</sup>

<sup>1</sup>*Bioprocess Laboratory, D-BSSE, Swiss Federal Institute of Technology (ETH), Basel, Switzerland*

Assays for activity assessment of genetically diverse libraries are generally done in three phases, i.e. seed, growth, and analysis. Each of these phases features a considerable number of manipulation steps (e.g. inoculation, addition of reagents) and the implicit need for a strict control of the environment (e.g. temperature, humidity, sterility). This complex workflow renders the analysis of libraries in high throughput mode a rather cumbersome and costly task

We employ nL-sized gel-carriers (nanoliter reactors or NLRs) kept in suspension arrays as growth and reaction compartments. Single library cells are embedded into NLRs and proliferated to microcolonies of a few 1'000 cells required for increase of the signal-to-noise ratio. The phenotype (e.g. biocatalyst productivity) is indicated by genetically encoded or chemical fluorescence reporters. Putative positive strains are

detected on the basis of the reporter signals and isolated by an appropriate technique such as large particle flow-cytometers.

We will provide a detailed overview of the technical elements required for nLR-screenings and present two application examples: *First*, screening for antibacterial peptides secreted by *Lactobacillus* libraries at rates of 1E5 / day. *Second*, identification of *Bacillus subtilis* strains catalyzing the conversion of cellobiose to the industrial product vitamin B2 at an elevated yield.

Both protocols are used on a regular basis. While the peptide libraries screens are performed by us, the B2 protocol has successfully been transferred to a professional environment thereby further accentuating the robustness of NLR technology.

#### **Creating the Facebook for Molecular Microbial Analysis**

P. Dorrestein<sup>1</sup>

<sup>1</sup>*Director, Collaborative Mass Spectrometry Innovation Center, Co-Director,  
Institute for Metabolomics Medicine,  
Skaggs School of Pharmacy & Pharmaceutical Sciences, La Jolla, USA*

The chemical make-up of microbiology is incredibly complex. It is already difficult to analyze the molecular make up of one organism, let alone 100s or 1000s of different organisms found in microbial communities? How can we look at the molecular make-up of all organisms at once? How many molecules do they have in common? How many are different? How do we retain the collective mass spectrometry knowledge of the community? As mass spectrometers are becoming faster and more sensitive we can detect a lot of molecular information. There are now mass spectrometers that can analyze 10,000 samples a day. However, there is no infrastructure to analyze this amount of molecular information or to correlate this information to other Big Data generating approaches such as sequencing. On average, however, only 1-5% of all the molecular information that is collected by mass spectrometry can be annotated. It is simply too much information for one person or lab to analyze this information with the existing tools that are available. In this lecture we will explore the strategies for organizing and visualizing the massive amount of information. Topics such as molecular networking, crowd source molecular analysis, 3D topographical mapping, MS/MS rarefaction, large scale mass spectrometry based genome mining, cross correlative analysis with molecular networking and pattern based genome mining will be covered.

<sup>3</sup>Station Agroscope Changins-Wädenswil, Swiss Federal Research, Nyon, Switzerland

Fungi possess inducible pathways that are activated in responses to stress that can produce highly bioactive defense compounds upon elicitation that need to be identified and investigated further for an evaluation of their biological properties and for a fundamental understanding of the chemical events that trigger various interactions between microorganisms. Metabolomics represents an ideal approach to highlight biomarker induction in such complex extracts. In this context the confrontation of various strains of human and plant pathogen fungi have been studied by an MS-based metabolomics approach that take advantages of UHPLC-TOF-MS fingerprinting and high resolution metabolite profiling for an efficient localization of stress-induced biomarkers. New chemometric algorithms that serve at the detection of MS features in complex mixture of fungal metabolomes have been devised. The *de novo* structure identification of novel stress-induced biomarkers was assured by subsequent LC-MS targeted microisolation and microflow NMR analyses. Various sampling, MS-based and data mining strategies were compared to highlight at best *de novo* metabolite stress-induction at the confrontation zone between microorganisms. Comparison of replicates obtained from miniaturized solid media co-culture produced in the 12-well plate format were found to be the best compromise for generating reproducible series of samples for further metabolite profiling. In some of the co-culture studied novel sulfated polyketides were evidenced in others quinonic pigments were highlighted to be strongly induced. No clear correlation between confrontation morphological patterns and metabolite induction could be made. In all cases however significant induction mechanisms were evidenced at the molecular level thanks to the advanced data mining approaches applied. *De novo* structure identification of the targeted metabolite was performed by HRMS and micro NMR after careful sample enrichment and chromatographic gradient transfer and MS-directed purification.

*Brucellae* are responsible for a worldwide zoonosis called brucellosis. These bacteria are able to invade a large range of host cell types. The intracellular trafficking of these bacteria is characterized by two successive steps: a first step in the endosomal compartments, where the bacteria do not grow, and a second step during which the bacteria proliferate massively, usually in the endoplasmic reticulum. Using fluorescent reporters for the monitoring of growth and chromosomal segregation at the single cell level, we showed that the cell cycle of *Brucella abortus* is blocked at the G1 stage during infection of HeLa cells and RAW 264.7 macrophages. This blockage occurs during the first stage of the infection. The cell cycle is resumed at the end of this first trafficking step, when bacteria are still in the endosomal compartments. These data show that cell cycle progression is coordinated with the intracellular trafficking of the bacterium. We thus investigated the role of a conserved transcription factor and regulator of cell cycle progression called CtrA. The predicted and experimental (ChIP-seq) CtrA regulons are consistent with a major role of CtrA for the control of cell growth, cell division and DNA methylation. Interestingly, CtrA is also proposed to control the segregation of chromosome II. Indeed, the *B. abortus* genome is split in two chromosomes, the segregation of newly replicated chromosome I origins occurring before the segregation of chromosome II origins. We propose that *B. abortus*, similarly to the model bacterium *Caulobacter crescentus*, is characterized by ordered cell cycle processes, such as pole maturation and successive initiations of chromosomal replication.

**Cell polarity and virulence**

**Cellular polarity and attachment in the plant pathogen *Agrobacterium tumefaciens***

C. Fuqua<sup>1</sup>, J.E. Heindl<sup>1</sup>, R. Natarajan<sup>1</sup>

<sup>1</sup>Biology, Indiana University, Bloomington, USA

*Agrobacterium tumefaciens* is best known for its ability to genetically modify plants through transfer and integration of a segment of DNA (T-DNA) into the plant genome, causing the disease called crown gall. Despite extensive studies of T-DNA transfer, little is known regarding the initial processes at the plant surface. *A. tumefaciens* forms dense biofilms on both abiotic and biotic surfaces which may increase the overall efficiency of transformation while affording protection against host defense responses. One of the primary factors mediating surface attachment in *A. tumefaciens* is called the unipolar polysaccharide (UPP), an adhesion produced at a single pole of the cell following surface contact. The UPP is one of several polarly localized cellular structures reported in *A. tumefaciens* including a tuft of unipolar flagella, and components of the Type IV secretion system (T4SS) that exports T-DNA. The cellular asymmetry is even more profoundly reflected in a polar mode of cell division for *A. tumefaciens*, in which cells multiply by budding and utilize a zonal mechanism of cell wall growth. Surface-attached *A. tumefaciens* cells generate daughter cells from their unattached pole, from which the flagella are also elaborated. The cellular asymmetry is under the control of a complex regulatory cascade designated the Control of Division and Development (CDD) pathway. Several related sensor kinases (PleC, DivJ, PdhS1 and PdhS2) and their cognate response regulators (DivK and PleD) converge on control of the CckA-ChpT-CpdR/CtrA CDD central circuit, and provide cell pole-specific modulation of division and polar development. UPP targeting to the old pole of the target cell is dependent on the PodJ protein, thought to function as a localization factor, whereas T4SS components concentrate at the pole independently of PodJ.

**The long and the short of it: heterogeneity and asymmetric growth in mycobacteria**

B.B. Aldridge<sup>1</sup>

<sup>1</sup>*Molecular Biology and Microbiology & Biomedical Engineering, Tufts University, Boston, USA*

*Mycobacterium tuberculosis* infects billions of people worldwide and kills more than 1.5 million per year. TB remains extremely difficult to treat with antibiotics, requiring months to years of therapy for cure. The variable course of disease and treatment response suggests that functionally heterogeneous populations of mycobacteria respond differently stress. Using a quantitative single-cell approach, we show that mycobacteria deterministically generate diversity in their growth characteristics through an asymmetric growth pattern. Coupled with a cell cycle regulated by time and not size, this asymmetry creates subpopulations of cells with distinct growth rates and cell sizes that are differentially susceptible to clinically relevant classes of antibiotics. Thus, the growth pattern intrinsic to mycobacteria deterministically creates a diverse population structure that may underlie phenotypes previously thought to be controlled by external stressors. We have also observed variation among microcolonies in antibiotic susceptibility that cannot be explained by growth pole age. Armed with new reporters of cell state and mathematical models, we seek to quantitatively characterize mycobacterial subpopulations with distinct behaviors arising from asymmetric growth and division.

**Cell polarity and virulence**

**It takes two to tango - the interplay between two nanomachines drives horizontal gene transfer in *Vibrio cholerae***

M. Blokesch<sup>1</sup>

<sup>1</sup>*Global Health Institute - School of Life Sciences,  
Swiss Federal Institute of Technology Lausanne (EPFL), Lausanne, Switzerland*

*Vibrio cholerae* is considered an important model organism for elucidating virulence regulation of facultative pathogens. In this context, the involvement of quorum sensing (QS) and of the type VI secretion system (T6SS) have been extensively studied even though the T6SS is been considered to be “silent” under laboratory conditions in pandemic *V. cholerae* O1 El Tor strains. Much less is known about the bacterium’s lifestyle in its natural environment, where it often associates with small crustaceans and their chitinous surfaces.

Here, we show that the chitin- and QS-dependent competence regulon of diverse pandemic and epidemic *V. cholerae* strains includes the T6SS-encoding gene clusters and that the T6SS contributes to enhanced horizontal gene transfer by means of natural transformation. We used live cell imaging to visualize components of the two competence-induced nanomachines of *V. cholerae*, namely the DNA uptake complex and the T6SS. Notably, such live-cell time-lapse imaging revealed that competence-mediated induction of the T6SS enhances horizontal gene transfer by deliberately killing neighboring non-immune cells and taking up their DNA via the competence-induced DNA uptake machinery.

FEMS Conference presentation

Speaker: Prof. Staffan Kjelleberg

Abstract title: Experimental mixed species biofilms: A novel approach to evaluating interactions at a community level

Our understanding of the mechanisms of biofilm development has largely been derived from studies on biofilm populations, yet biofilms predominantly exist as communities. This lack of investigation into multispecies consortia reflects the relative ease by which the biofilm life cycle can be experimentally interrogated for single species systems and the difficulty to maintain experimentally tractable biofilm community systems. We have employed experimental mixed species biofilm communities to bridge this gap, also allowing us to explore mechanisms in more ecologically relevant systems and test theories from eukaryote ecology. The biofilm life cycle of two biofilm community systems – a defined three species biofilm community and a phylogenetically highly diverse biofilm granulation system – will be addressed. For the former, the establishment of a mixed defined community of *Pseudomonas aeruginosa*, *Pseudomonas protegens*, and *Klebsiella pneumonia*, has been employed to demonstrate community specific contributions to biofilm development, resistance to chemicals and predation, and variant formation by the individual member species. These findings report on mechanisms that regulate cross species interactions but which are not available for monospecies biofilms formed by either of the three members. The second experimental biofilm community system, exploring the life cycle of high species diversity granular biofilms reveals that quorum sensing signaling is a distinct community regulatory process. Here, signal producers and degraders are phylogenetically diverse and dissimilar, while a minority of the community members are capable of entertaining both signaling synthesis and quenching, as is the case for our understanding of QS signaling biology in population based model biofilms. Crucially, the granular biofilm life cycle is driven by differentiated community signaling that reflects community shifts in phylogeny, signaling synthesis and quenching.

<sup>3</sup>*Department of Molecular Microbiology, University of Leuven, Leuven, Belgium*

The clinical significance of microbial interactions in a host particularly those between opportunistic pathogens such as *Candida albicans* and *Staphylococcus aureus* remains largely understudied mainly due to lack of suitable animal models. To that end, we developed mouse models of co-infection to investigate the clinical implications of mixed species biofilms on host tissue and implanted catheters. In the first model, animals were orally infected with *C. albicans* and following development of oral candidiasis animals were exposed to *S. aureus* through drinking water. Findings from this model demonstrated that the extensive tissue damage caused by invading *C. albicans* hyphae provided an inlet for the typically non-invasive *S. aureus* to disseminate to the kidneys causing high morbidity and mortality. Additionally, a mouse subcutaneous catheter model was used to study *in vivo*-grown biofilms where co-infected catheter fragments were implanted subcutaneously in the animals. Following 6 days, analysis of explanted catheters revealed the formation of a thick biofilm within the catheter lumen consisting of both species embedded in a matrix. Further analysis indicated increase in *S. aureus* produced eDNA in mixed biofilms and enhanced tolerance of *S. aureus* to vancomycin. Combined the findings from these studies demonstrated that the onset of oral candidiasis may constitute a risk factor for disseminated bacterial disease. Further the co-adherence of *C. albicans* and *S. aureus* to abiotic surfaces results in formation of resistant biofilms on indwelling medical devices. These novel findings demonstrate the gravity of *C. albicans*-*S. aureus* interactions in the host, warranting awareness in terms of prophylactic therapeutic measures.

**Candida albicans-Staphylococcus aureus intra-abdominal infections: at the crossroads of inter-Kingdom virulence and host response**

B. Peters<sup>1</sup>, E. Nash<sup>2</sup>, P. Fidel Jr.<sup>2</sup>, M. Noverr<sup>1</sup>

<sup>1</sup>Prosthodontics, LSU Health Sciences Center, New Orleans, USA

<sup>2</sup>Microbiology Immunology & Parasitology, LSU Health Sciences Center, New Orleans, USA

The polymorphic fungus *Candida albicans* and the ubiquitous bacterial pathogen *Staphylococcus aureus* are common co-infecting microbes during intra-abdominal infections (IA), often resulting in high morbidity and mortality. Using a murine model of IAI, our previous work demonstrated that synergistic host inflammation (specifically, prostaglandin E2) is associated with mortality. However, the microbial virulence factors contributing to infectious synergism remain undefined.

Previous studies suggested that staphylococcal toxins were associated with poor outcome during murine IAI. Thus, we hypothesized that *C. albicans* may augment the expression of *S. aureus* toxins during co-infection. To test this hypothesis, cultures of *S. aureus*, *C. albicans*, or both organisms together were grown under planktonic or biofilm growth conditions. Cell-free supernatants from polymicrobial cultures showed increased hemolysis *in vitro*. Use of an isogenic *S. aureus*  $\Delta agrA$  mutant confirmed that enhanced hemolysin production was *agrA*-dependent. Use of a GFP-reporter plasmid demonstrated enhanced *agr* activity in co-culture as compared to monomicrobial growth, and qPCR and Western blot analysis of *agr*-regulated genes further supported these results. Lastly, mice were intraperitoneally inoculated with sub-lethal doses of *C. albicans*+*S. aureus*, *C. albicans*+*S. aureus* ( $\Delta agrA$ ), or *S. aureus* alone and monitored for morbidity and mortality. Alarming, 80% of the mice co-inoculated with *C. albicans*+*S. aureus* (WT) succumbed by d 1 post-inoculation, while only 30% of the mice co-inoculated with *C. albicans*+ $\Delta agrA$  succumbed to the infection (d 8 post-inoculation). All mice inoculated with JE2 alone survived throughout the infection time course. Furthermore, assessment of  $\alpha$ -toxin in the lavage fluid by immunoblot and ELISA confirmed increased toxin during co-infection, despite similar bacterial burden as monomicrobial infection.

In summary, *C. albicans* can augment *S. aureus* toxin production, potentially explaining the devastating pathology of fungal-bacterial IAI.

**Contribution of bacterial volatile molecules to the dynamics of polymicrobial bacterial biofilm communities**

J.M. Ghigo<sup>1</sup>

<sup>1</sup>*Department of Microbiology, Institut Pasteur, Paris, France*

Bacteria produce and sense a high diversity of signals and cues to adapt their behaviors to changing environments. Among them, volatile compounds produced by fungi and plants were shown to modify bacterial phenotypes and activities. However, besides being perceived as odors, attractive scents or pollutants, the influence of bacterial volatile molecules on bacterial biology itself remained poorly explored. I will discuss how some bacterial volatile compounds diffusing in heterogeneous environments, such as soil, organic tissues and microbial mats can mediate airborne chemical interferences and contribute to shape polymicrobial bacterial communities.

**An evolutionary view of the Holobiont theory and its implications for host development**

S. Petterson<sup>1,2</sup>

<sup>1</sup>*Karolinska Institutet, Sweden*

<sup>2</sup>*LKC School of Medicine, Nanyang Technical University, Singapore*

The mammalian microbiome is formed out of a maternal hand-over of microbes, diet and lifestyle that will influence host physiology throughout life. Moreover, microbes and its host also share, in part, their biological and biochemical needs. This assumption forms the basis of the Holobiont theory. This theory of evolution proposes that the object of natural adaptation and selection is not the host (its genes and organs), but the host together with its microbiome (all genes and its metabolites) - The Holobiont. When the host – The Holobiont - is challenged by dramatic changes, such as alteration in dietary intake, malnutrition, reduced physical activity or unwanted severe stress, a Holobiont will employ strategies and adaptation mechanisms to handle these changes including signals transmitted to the microbiome community. The microbiome in turn, will reciprocate and transmit signals to its host. The last decades of reductionist research aiming to decipher the underlying mechanisms responsible for the epidemic development of life style related diseases, by use of Genome Wide Association Studies has not considered the Holobiont perspective and consequently, the adaptation strategies developed by the microbiome and its signals transmitted to the host has not been included in the analysis. In my presentation I will discuss the Holobiont concept and present data which support how a host responds to this bilateral microbiome-host communication related to development and metabolic homeostasis.

**FEMS-3161**

**Gut Microbiota and Type 2 Diabetes**

F. Bäckhed<sup>1</sup>

<sup>1</sup>*Wallenberg laboratories, University of Gothenburg, Sweden*

The human gut is inhabited with trillions of bacteria, gut microbiota, that have co-evolved with us and affect our physiology within and outside the gut. The gut microbiota has recently been suggested as a novel contributor to obesity and related comorbidities, such as type 2 diabetes (T2D) and cardiovascular diseases (CVD). We recently found that the gut microbiota is altered in patients with CVD and T2D and that we can classify patients and T2D patients based on the microbiota. Using germ-free mice we have causally linked the gut microbiota to obesity and insulin resistance and have recently found that the gut microbiota modulates adipose inflammation, bile acid signaling, and enteroendocrine cell function. However, the underlying mechanisms(s) by which the gut microbiota induces signalling is yet to be dissected. By combining defined microbial communities, multi-omics approaches with genetically modified mice we are beginning to clarify host microbial interactions and their metabolic responses.

**FEMS-2795****The Species Concept in the Genomic Era Supported by the Bergey's Manual Trust and Organized by ICSP****Genome sequences as nomenclatural type material for novel taxa**

W. Whitman<sup>1</sup>

<sup>1</sup>*Microbiology, University of Georgia, Athens, USA*

Major goals of the Bacteriological Code are to provide all prokaryotic species with a single name and insure that each name refers to a single species. Currently, these goals are achieved in part through designation of type strains, which are viable cultures deposited in two public culture collections. These cultures then become the reference material for comparison to the type strains of other validly described species.

The genome sequence provides sufficient information to satisfy the goals of the Bacteriological Code for type material. Based upon genome sequence similarities, it is possible to determine if two strains are members of the same species. The genome sequence also provides sufficient information about the growth properties, physiology, metabolism, and lifestyle to support polyphasic classifications. Thus, the Bacteriological Code should be modified so that genome sequences from clonal populations or single cells are acceptable type materials upon deposition of DNA to insure authenticity.

This change will allow naming of taxa not readily cultivated by service culture collections and uncultured taxa. Moreover, the current system was developed when the number of type strains was in the thousands. The number of type strains is now greater than 12,000 and continues to increase. Culture collections are unfairly burdened with the task of maintaining and distributing this large number of strains. Allowing genome sequences to serve as type material will allow culture collections to reallocate resources to the most important and valuable cultures.

**Applying an evolution-based species concept for the delineation of bacterial species: The *Pantoea* example**

S.N. Venter<sup>1</sup>, M. Palmer<sup>1</sup>, M.P.A. Coetzee<sup>2</sup>, T.A. Coutinho<sup>1</sup>, E.T. Steenkamp<sup>1</sup>

<sup>1</sup>Microbiology and Plant Pathology CTHB Forestry and Agricultural Research Institute and Genomics Research Institute, University of Pretoria, Pretoria, South Africa

<sup>2</sup>Genetics CTHB Forestry and Agricultural Research Institute and Genomics Research Institute, University of Pretoria, Pretoria, South Africa

Bacterial species are commonly defined by applying a set of predetermined criteria, such as DNA:DNA hybridization values, 16S rRNA sequence similarity and phenotypic and chemotaxonomic comparisons. Alternative genome-based similarity criteria have also been proposed to define bacterial taxa. We have previously shown that the metrics based on genome data support all of the validly described *Pantoea* species. However, the question remained whether the same species would have been recognised when taxa were delineated using an evolution-based species concept instead of fixed or quantitative criteria. Here we utilized *Pantoea* and the available genome data to investigate whether an evolution-based concept, in which species represent unique and genealogically exclusive groups of isolates on phylogenetic trees, would allow for delineation of the known species.

The core genomes (genes present amongst all member of the group) for *Pantoea* species were determined. These genes were subjected to phylogenetic analyses as they collectively represent the dominant evolutionary signal that depicts vertical descent. The core gene content was also characterized in terms of general cellular functions.

The *Pantoea* core genome consisted of approximately 2500 genes and differed markedly from the genomes of other closely related genera. Similar phylogenies were inferred for the various functional sets of genes. Although slight changes in sister relationships were observed for some of the species, the examined *Pantoea* species all represented exclusive genealogical groups. Our results thus indicated that a genome-based comparative and evolutionary approach could be a preferred alternative to fixed criteria when delineating coherent bacterial taxa.

<sup>3</sup>*Ribocon GmbH, Ribocon GmbH, Bremen, Germany*

<sup>4</sup>*Molecular Ecology, Max Planck Institute for Marine Microbiology, Bremen, Germany*

**Background:**

Molecular tools applied to understand microbial diversity have evidenced the very large extent of undescribed taxa. The estimated richness exceeds in orders of magnitude the current ~12,000 classified species. However, there is a need to find faster ways to catalogue the biosphere's diversity, and try to overcome the major problem in classification that is bringing the type material into pure culture.

**Objective:**

For this study we have measured the extent of hitherto discovered putative taxa in 16S rRNA gene databases using taxonomic thresholds that have been previously calculated with all cultured *Bacteria* and *Archaea*. In addition, we have evaluated the current species definition and its application to recognize uncultured microbial populations thriving in natural environments and detected through metagenomic approaches.

**Conclusions:**

The current species definition for prokaryotes is strongly based on its circumscription by genome sequence comparisons and genetic distances of housekeeping genes, together with a discriminative phenotypic property. The set of environmental 16S rRNA gene sequences in public repositories matched about 250,000 species, 80,000 genera and 1,300 phyla, and the predicted total number of species in the biosphere ranges from  $10^6$  –  $10^7$ . In addition, the new sequencing technologies allow retrieving individual population's (meta)genomes of uncultured organisms that can be used to understand their phylogeny and genomic uniqueness, and predict their metabolism as for cultured organisms. This will allow implementing metagenomics into the *Candidatus* proposals of organisms not showing conspicuous prominent characters, and speed up the description of uncultured organisms in a similar way to those in pure culture.

## FEMS-2708

### The Species Concept in the Genomic Era Supported by the Bergey's Manual Trust and Organized by ICSP

#### Type species in the genomic era of Mollicutes

D.R. Brown<sup>1</sup>, M.A. May<sup>2</sup>

<sup>1</sup>Infectious Diseases and Pathology, University of Florida, Gainesville FL, USA

<sup>2</sup>Biomedical Sciences, University of New England, Biddeford ME, USA

Since its inception, the International Code of Nomenclature of Bacteria has emphasized the importance of type material as a reference to be used when considering the identity of specimens. Nomenclatural types also permanently bear the name of the taxon. Investigators expect that types should exemplify the defining characteristics of the taxon as it exists within a hierarchy of superior taxa. The Code is sufficiently flexible to allow that types later realized to be unsuitable can be replaced with neotypes as knowledge advances.

The type of genus *Mycoplasma*, hence the *Mycoplasmataceae*, *Mycoplasmatales* and class *Mollicutes* is *Mycoplasma mycoides* subsp. *mycoides* strain PG-1<sup>T</sup>. Modern phylogenetic analyses situate *M. mycoides* in the distant order *Entomoplasmatales*, so if discovered today PG-1 would be doubtfully referred to *Mycoplasma*. Our objective was to explore genomic methods that might be used to identify candidates for neotype of the genus.

A well-chosen neotype might be expected to exhibit genomic consistency with others in its genus. JSpecies was used to calculate ANI values by pairwise comparisons of the complete genome sequences of 20 species representing six families within class *Mollicutes*. ANIm was calculated by the NUCmer algorithm of MUMmer and ANIb was calculated by reciprocal BLASTN. The alignment-free tetranucleotide frequency correlation coefficient was also calculated. The matrices were visualized as unrooted trees using PHYLIP, then reviewed by the ICSP Subcommittee on the taxonomy of *Mollicutes*. The Subcommittee unanimously agreed that the genomic trees were not congruent with the shared view of the taxonomic structure of the class. Although evidently not suitable for determination of supraspecific relationships, genomic analyses remain valuable for species-level circumscription of mollicutes.

### **Antibiotic resistance and environment**

#### **Antibiotic resistance in the urban water cycle: origins, fate and risks**

C.M. Manaia<sup>1</sup>

<sup>1</sup>CBQF – Centro de Biotecnologia e Química Fina – Laboratório Associado Escola Superior de Biotecnologia, Universidade Católica Portuguesa, Porto, Portugal

The urban water cycle refers to the journey of water from the collection, disinfection and purification for human consumption to its return to nature as treated wastewater. Over this cycle, water is inhabited by different bacterial populations, some strictly environmental, others of human or animal origin, most of which considered contaminants. Multidrug resistant bacteria, sometimes harboring antibiotic resistance (AR) genes of clinical relevance, are commonly found in each of these aquatic environments.

It is estimated that AR bacteria are responsible annually for > 20000 deaths, in both the US and the EU. Although these values are registered in the clinical settings, it is recognized that the environment, in particular water, plays an important role on the dissemination of AR from and to humans.

Urban wastewater, either raw or treated and ready to discharge in the environment, presents a high prevalence of AR to “old” antibiotics, suggesting the cumulative effect of this form of contamination. Moreover, almost all AR genes of clinical concern can be detected in wastewater, suggesting their rapid dissemination.

In contrast, drinking water, in principle free of pathogens, is inhabited by an impressive diversity of environmental bacteria, some of which exhibit multidrug resistance phenotypes, probably intrinsic in those species. Although not posing an acute problem of AR dissemination, intrinsically AR bacteria may have also adverse human health effects.

Nowadays, it is difficult to assess the risks of the transmission, directly or indirectly, of AR bacteria from the environment to humans. A major limitation is related with the absence of surveillance and data sharing systems comprising both environmental and clinical data, allowing a global overview of the emergence and evolution of AR and how it can affect human health.

**Disinfection of urban wastewater by conventional and new processes: effect on antibiotic resistance**

L. Rizzo<sup>1</sup>

<sup>1</sup>*Civil Engineering, University of Salerno, Fisciano, Italy*

The effluents of urban wastewater treatment plants (UWWTPs) are among the main point sources of antibiotic resistance pollution of surface waters. In several countries, disinfection process is the last step of UWWTPs to minimize the release of antibiotic resistant bacteria and genes (ARB&Gs) in the effluent. But in some country UWWTP effluent is disposed in the receiving water body without any disinfection treatment. Typical disinfection processes include chlorination and UV radiation but other disinfectants/oxidants such as ozone, chlorine dioxide and hydrogen peroxide are also used. Unfortunately, ARB&Gs have been detected in the effluents of UWWTPs raising the suspect that conventional disinfection processes (particularly chlorination and UV radiation) not effective in controlling antibiotic resistance spread into the environment. Therefore, in the last years non conventional disinfection technology such as that based on Advanced Oxidation Processes (AOPs) has been investigated as possible alternative to conventional disinfection processes for controlling antibiotic resistance spread.

In this work the results of disinfection experiments by chlorination, UV radiation and AOPs are summarized. The effect of disinfection processes on antibiotic resistant *E. Coli* (from the effluent of secondary treatment of an UWWTP) in terms of inactivation, bacterial regrowth and antibiotic resistance was evaluated. Moreover, the effect of an AOP (namely TiO<sub>2</sub> photocatalysis) on the mechanism of antibiotic resistance transfer was also investigated.

AOPs can be more effective than conventional disinfection processes in the inactivation of ARB but further studies on the effect of AOPs on antibiotic resistance transfer are needed to better understand the potential of residual ARB and mobile genetic elements of transferring antibiotic resistance after disinfection treatment.

<sup>3</sup>*Department of Biological and Environmental Sciences, University of Gothenburg, Gothenburg, Sweden*

<sup>4</sup>*Department of Shipping and Marine Technology, Chalmers University of Technology, Gothenburg, Sweden*

#### **Background**

A mixture of antibiotics and co-selective agents, such as biocides and metals, reach the environment through sewage effluents. It is unknown to what extent antibacterial agents select and co-select for resistance in aquatic ecosystems e.g. wastewater treatment plants and receiving waters.

#### **Objectives**

The aim was to determine the minimal selective concentration (MSC) of an antibiotic (tetracycline) and the minimal co-selective concentrations (MCCs) of a common biocide (cetyl trimethyl ammonium chloride; CTAC) in complex aquatic bacterial communities.

#### **Methods**

Treated sewage effluent (Gothenburg, Sweden) was diluted and used as inoculum to establish biofilms in flow-through systems containing different concentrations of antibacterial agents. Biofilms were screened for their resistance/tolerance using selective plating, characterization of isolates, metagenomics analyses (resistance genes and taxonomic composition), and pollution induced community tolerance (PICT).

#### **Conclusions**

Concentration-response curves for tetracycline were obtained for selective plating, *tet*-genes and PICT. Based on selective plating the MSC of tetracycline was 10ng/mL ( $p=0.009$ ), which correlates well with an increased MIC<sub>50</sub>-value (concentration inhibiting 50% of the isolates). Increases of other resistance genes, ISCR2 and *int1* were observed with increasing tetracycline concentrations. Effects of tetracycline on taxonomic composition are under evaluation.

CTAC selects for self-tolerance and co-tolerance to chloramphenicol, tetracycline and erythromycin. The MCCs of CTAC as well as effects on resistance gene frequencies and taxonomy remain to be evaluated.

Knowledge of the selective and co-selective properties of tetracycline and CTAC generated here will facilitate the establishment of safe emission limits. This could guide actions to reduce risks for resistance selection in the environment.

**EXPLORING PLASMID-BASED DISSEMINATION OF ANTIBIOTIC RESISTANCE GENES IN ENVIRONMENTAL MATRICES**

*C. Merlin<sup>1</sup>, X. Bellanger<sup>1</sup>, H. Guilloteau<sup>1</sup>, H. Scornec<sup>1</sup>*

*<sup>1</sup>LCPME, Université de Lorraine, Nancy, France*

**Background**

Plasmids are important actors of antibiotic resistance gene dissemination that contribute to reduce the effectiveness of our therapeutic potential.

**Objectives**

Our objectives are to identify permissive environments and/or conditions driving plasmid transfer in microbial communities.

**Methods**

Lately, we developed a sensitive molecular approach based on qPCR allowing the detection of rare transfer events of known plasmids in natural microbial communities. Basically, it consists in inoculating microcosms with a donor bacterium and to quantify the relative abundance of both the plasmid and the initial host DNAs over time. Since conjugative transfer is an intercellular mode of DNA replication, the plasmid to donor DNA ratio increases in the community DNA when the plasmid transfers into the indigenous population.

**Conclusions**

The transfer of the broad host range IncP-1 $\beta$  plasmid pB10 was studied in various environmental matrices. Under low level of inoculation, the transfer of pB10 in complex environments appeared relatively rare and was strongly matrix dependent. In some instance, the transfer of pB10 appeared influenced by eukaryotic predation, which alternatively could promote or inhibit plasmid transfer depending on the environmental matrix considered. An estimation of the IncP-1 $\alpha/\beta$  plasmids abundance by qPCR demonstrated that pB10 transfer tends to be supported by environmental matrices exhibiting a higher content of IncP-1 $\alpha/\beta$  plasmids. This tend to show that the relative abundance of IncP-1 plasmids in a given microbial community reflects its permissiveness to the transfer of plasmids belonging to the same incompatibility group, which seemed to prevail over transfer limitation due to the superinfection immunity (exclusion & incompatibility).

**METAL SPECIFIC MODULATION OF COMMUNITY PERMISSIVENESS  
TOWARDS BROAD HOST RANGE PLASMIDS THROUGH STRESS**

U. Klümper<sup>1</sup>, K.K. Brandt<sup>2</sup>, A. Dechesne<sup>1</sup>, L. Riber<sup>3</sup>, S.J. Sørensen<sup>3</sup>, B.F. Smets<sup>1</sup>

<sup>1</sup>*Environmental Engineering, Technical University of Denmark, Kgs. Lyngby, Denmark*

<sup>2</sup>*Department of Plant and Environmental Sciences, University of Copenhagen, Copenhagen, Denmark*

<sup>3</sup>*Department of Biology, University of Copenhagen, Copenhagen, Denmark*

**Background**

The extent by which antibiotic resistance encoding conjugal plasmids transfer in microbial communities is of acute relevance in the age of massive antibiotic usage. The occurrence of stressors, like metals, might play a major role in altering the acute permissiveness of a bacterial community, since plasmid transfer is considered a main process in immediate stress response and adaptation to environmental changes.

**Objectives**

We evaluated: Does the introduction of metal stress alter a soil community's permissiveness towards plasmids? Is a potential stress response general or a metal specific?

**Methods**

Hence, using a [3H]-leucine incorporation approach, we measured 20% and 50% inhibition concentrations for 5 metals. A *mCherry*-tagged donor carrying the *gfp*-tagged plasmid pKJK5 was mated with a soil bacterial community and exposed to metal stress. Transconjugants were quantified and isolated using advanced microscopy and fluorescent activated cell sorting. Sorted transconjugants were analyzed by pyrosequencing.

**Conclusions**

The imposed metal stress lowered the plasmid transfer frequency in filter mating assays. The intensity of this effect was metal specific and couldn't be explained by measured growth inhibition of the recipient community because the exposure was normalized to similar inhibition. Results revealed an effect on transconjugant diversity for the heavy metals, Nickel or Copper, while Arsenic exposure caused no effect. The changes in transconjugal pool diversity couldn't be directly correlated to a change in community diversity through the introduced stress. Our results suggest that this effect is not general but corresponds to a metal specific stress response of the soil microbial community with regard to plasmid transfer.

## EXPLORATION OF THE REMOVAL POTENTIAL OF WASTEWATER ANTIBIOTIC RESISTANCE GENES BY SELECTED PHOTOCATALYTIC AND BIOLOGICAL TREATMENT TECHNOLOGIES

*P. Karaolia<sup>1</sup>, J. Alexander<sup>2</sup>, T. Schwartz<sup>2</sup>, D. Fatta-Kassinos<sup>1</sup>*

<sup>1</sup>Nireas-International Water Research Centre, University of Cyprus, Nicosia, Cyprus

<sup>2</sup>Institute of Functional Interfaces, Karlsruhe Institute of Technology, Karlsruhe, Germany

### Background

The pressure applied onto bacteria in aquatic environments by the extensive use of antibiotics, leads to increased incidence of antibiotic resistance (AR) (Volkman et al., 2004), increasing the prevalence of nosocomial diseases. There is limited research regarding alternative actions of controlling AR in wastewater treatment plants (WWTPs), i.e. advanced oxidation processes (AOPs) and new biological methods which may remove AR more efficiently (Rizzo et al., 2013).

### Objectives

The aspects examined were: i) the prevalence of selected AR genes (ARGs) at different steps of the WWTP process ii) the ARGs removal efficiency (*vim*, *vanA*, *mecA* and *lak* genes) of a pilot scale Membrane BioReactor (MBR) and of two AOPs (solar photo-Fenton treatment and heterogeneous (TiO<sub>2</sub>) photocatalysis).

Step of treatment	Detector	% change (/100 ng of total DNA)	Detector	% change (/100 ng of total DNA)	Detector	% change (/100 ng of total DNA)	Detector	% change (/100 ng of total DNA)
Primary influent		-		-		-		LOD
MBR Mixed liquor Suspended Solids		28		67		69		-
MBR effluent	<i>vanA</i> Sybr	4400 (increase)	<i>lak1</i> Sybr	509 (increase)	<i>vim1</i> Sybr	18100 (increase)	<i>mecA</i> Sybr	-
Solar photo-Fenton treatment		7300 (increase)		6500 (increase)		99		-
TiO <sub>2</sub> heterogeneous photocatalysis		98		96		96		-

**Table 1.** Removal of examined antibiotic resistance genes after the investigated AOPs and biological treatment.

### Methods

The AOP experiments took place under bench-scale conditions while the MBR had a capacity of 10 m<sup>3</sup> day<sup>-1</sup>. Real-time qPCR assessment followed the filtration and DNA extraction of the samples.

### **Conclusions**

The highest prevalence of *lak* and *vanA* genes was found in solar photo-Fenton effluent. The highest *vim* prevalence was found in MBR effluent (Table 1), indicating an increase in the examined ARGs after treatment. Further optimization of the examined technologies must occur to ensure safe disposal of treated effluents into aquatic ecosystems.

This work was funded by COST through a Short Term Scientific Mission (STSM) within the COST scientific programme on 'Detecting evolutionary hotspots of antibiotic resistance in Europe (DARE)'. Nireas-IWRC (NEA ΥΠΟΔΟΜΗ/ΣΤΡΑΤΗ/0308/09) is co-financed by the Republic of Cyprus and the European Regional Development Fund through the Cyprus Research Promotion Foundation.

Bacterial spores are ubiquitous in nature. They are stress resistant entities that can withstand high environmental temperatures, chemical insults and physical stress such as radiation or increased pressure. Spores are a concern to microbiological food stability due to these characteristics as upon survival of a preservation process they may start to germinate and grow out in food causing food spoilage. In addition germinating and outgrowing spores at undesired times and places pose a significant health burden. The challenge is amplified due to the heterogeneous germination and outgrowth behaviour of an isogenic spore population. We set out to analyse effects of thermal stress and the presence of a weak organic acid preservative on *Bacillus subtilis* spores of different maturation stages. Spore germination and outgrowth was assessed using live-imaging including the monitoring of intracellular pH with IpHluorin. Significant heterogeneity in spore germination and outgrowth was observed and monitored using the newly developed Sporetracker image analysis tool. Thermal stress clearly enhances heterogeneous germination behaviour. To analyse whether different levels of spore coat cross-linking may be involved in the (heterogeneous) stress response we set out to identify such cross-links by mass-spectrometry analysis of the insoluble coat fraction of *B. subtilis* spores of different maturation levels. Heat resistance of spores from all samples was also tested. Using our gel-free proteomic approach and LC-FTICR-MS/MS analysis we monitored the efficiency of tryptic digestion of proteins in the coat during spore maturation over a period of 10 days, using metabolically <sup>15</sup>N labelled mature spores as a reference. The results showed that during spore maturation the loss of digestion efficiency of outer coat (for instance CotG, CotC, CotU) and crust (CotY, CotZ) proteins synchronized with an increased heat resistance.

#### **The sweet secrets of industrial strain improvement**

A.R. Neves<sup>1</sup>

<sup>1</sup>*Bacterial Physiology & Improvement, Chr. Hansen A/S, Hørslø, Denmark*

Lactic acid bacteria (LAB) are a functionally related group of Gram-positive bacteria known essentially for their roles in food bioprocessing. The successful biotechnological application of LAB depends to a great extent on their unique phenotypic traits, which among others include fast acidification of the medium, texture and flavour forming abilities, bioprotection, and health promoting properties. However, the highly dynamic food market and ever-changing preferences from end consumers demands constant focus on product development. Fostered by this market push, Chr. Hansen places continuous efforts into the development of new LAB strains and cultures with novel properties and superior performance for the dairy industry. In the 21<sup>st</sup> century, genetic engineering could make such tasks more ease to accomplish. However, the tight requirements of regulatory agencies and the negative perception by consumers of genetically modified foods impose the exclusive use of natural strain improvement methodologies. Thus, at Chr. Hansen innovative product development includes combining classical strain improvement techniques such as random mutagenesis, dominant selection, adaptive laboratorial evolution, with the insights gained from the molecular understanding of our model systems. This approach will be illustrated with relevant example cases of strain improvement for the dairy industry.

**A MOBILE GENETIC ELEMENT IS RESPONSIBLE FOR SUBSTANTIALLY  
INCREASED HEAT RESISTANCE OF BACILLUS SUBTILIS SPORES**

E.M. Berendsen<sup>1</sup>, O.P. Kuipers<sup>1</sup>, M.H.J. Wells-Bennik<sup>2</sup>

<sup>1</sup>Molecular Genetics, University of Groningen, Groningen, Netherlands

<sup>2</sup>Food Safety, NIZO Food Research B.V., Ede, Netherlands

**Background**

Spores of *Bacillus subtilis* are able to survive various harsh environmental conditions, including different heat preservation treatments used in food processing. Twenty strains of *B. subtilis* could be divided into two distinct groups with different spore heat resistances where the high spore heat resistance group required 100 times longer heating at 120°C to obtain the same level of spore inactivation.

**Objectives**

The goal of this study was to identify a genomic determinant for increased spore heat resistance, and to understand the underlying molecular mechanism mediating this increase in heat resistance of spores.

**Methods**

Whole genome sequencing was performed for these food isolates of *B. subtilis*, followed by correlating the genome content to the corresponding spore heat resistance phenotype. A transposon was identified and the insertion location was verified by PCR. Transfer of this element was achieved using filter mating.

**Conclusions**

A set of genes were uniquely present in the strains producing spores with increased heat resistance, and were located on transposon. The integration site of the transposon was found in the same gene for all strains producing high heat resistant spores. We demonstrated that the transposon was directly responsible for the very high heat resistance of spores; transfer of the transposon to a strain with significantly lower heat resistance (*i.e.* *B. subtilis* 168) rendered a phenotype of high spore heat resistance. The exact molecular mechanisms that mediate the increase of spore heat resistance are not known and the role of the genes on the transposon is currently subject of further investigation.

**RECONSTRUCTION OF THE METHIONINE TO CYSTEINE CONVERSION  
PATHWAY IN LACTOBACILLUS PARACASEI FAM18149 BASED ON  
COMPARATIVE GENOMICS AND WHOLE TRANSCRIPTOME ANALYSIS**

D. Wüthrich<sup>1</sup>, R. Bruggmann<sup>1</sup>, T. Bavar<sup>2</sup>, H. Berthoud<sup>2</sup>, S. Irmeler<sup>2</sup>

<sup>1</sup>Interfaculty Bioinformatics Unit and Swiss Institute of Bioinformatics,  
University of Bern, Bern, Switzerland

<sup>2</sup>Food Analytics, Agroscope Institute for Food Sciences, Bern, Switzerland

**Background**

The flavor of cheese results from metabolic activities of bacteria like *Lactobacillus paracasei* during cheese ripening. Among many others, volatile sulfur compounds (VSCs) such as methanethiol, methional and hydrogen sulfide are key flavor compounds. Methionine is the main sulfur source in cheese, and is probably the precursor for bacterial VSC production. We observed that various strains of *L. paracasei* grew in medium that contained methionine as the sole sulfur source. Interestingly, these strains were also capable to produce VSCs.

**Objectives**

*L. paracasei* strains that grow with methionine as sole sulfur source have the potential to be used as flavor enhancing adjunct cultures in cheese making. A better understanding of the pathways involved in the metabolism of methionine by this species is of importance for proper strain selection.

**Methods**

*L. paracasei* FAM18149 was grown in medium with cysteine as only sulfur source and in medium with methionine as only sulfur source. The transcriptome of both conditions was measured using RNA-seq. The significantly regulated genes were studied in a gene trait analysis including genomes of 23 additional strains.

**Conclusions**

We found 55 significantly regulated genes. Among the regulated genes we identified a cluster that is only present in strains that grow with cysteine as only sulfur source. The cluster consists of a cysteine synthase, a cystathionine gamma-/beta-lyase and a serine acetyltransferase.

Based on these results we were able to reconstruct the whole pathway of methionine to cysteine conversion and show that the cluster comprises the key enzymes of the pathway.

**Food biotechnology**

**MLST ANALYSIS TO CHARACTERIZE THE STRESS RESPONSE IN LACTOBACILLUS PARACASEI.**

*F. Ginaldi<sup>1</sup>, M. Manzano<sup>1</sup>, M. Vendrame<sup>1</sup>, G. Comi<sup>1</sup>, L. lacumin<sup>1</sup>*

*<sup>1</sup>Department of Food Science, University of Udine, Udine, Italy*

Background: The interest regarding the genetic variability among *L. casei* group members is increasing. These information are highly relevant in order to improve the knowledge and understand the correlation between genetic traits and biological properties, but also phenotypic characteristics and industrial properties of the strains. Objectives: The study of the correlation between the genetic profile of the strains and the stress response.

Methods: 25 *L. paracasei* strains were selected for MLST analysis; 8 genes related to stress response (*ctsR*, *hrcA*, *cydD*, *cydA*, *nox*, *npr*, *pox*, *dnaK*) were chosen as target genes. After the comparison of the obtained sequences, a Sequence Type (ST) number was assigned to each strain. MEGA version 6.06 software (<http://www.megasoftware.net>) was used to compare and align the sequences and phylogenetic trees were constructed using the UPMGA. DnaSP software version 5.10.1 was used to perform the descriptive analysis.

Conclusions: After PCR of the internal sequences of the selected loci (*npr*, *nox*, *hrcA*, *ctsR*, *cydA*, *cydD*, *dnaK*, and *pox*), the amplicon was obtained for all the tested strains, confirming the presence of the target genes. All the studied strains resulted having a different Sequence Type (ST). The mean G + C content of the different gene fragments was higher than 0.45, meaning that the analysed genes are almost stable. Observing the MLST UPGMA trees, the strain's cluster confirmed a correlation between the different genetic profile of the stress related genes and the different stress resistance of the strains.

**LISTERIA MONOCYTOGENES SURVIVAL STRATEGIES: POPULATION  
HETEROGENEITY AND STRESS RESISTANT VARIANTS**

T. Abee<sup>1</sup>, K.I. Metselaar<sup>1</sup>, I.K. van Boeijen<sup>1</sup>, H.M. den Besten<sup>1</sup>, M.H. Zwietering<sup>1</sup>

<sup>1</sup>Laboratory of Food Microbiology, Wageningen University, Wageningen, Netherlands

**Background**

The food-borne pathogen *Listeria monocytogenes* is a Gram-positive microaerophilic facultative anaerobic rod and the causative agent of listeriosis. This pathogen is notorious for its robustness and a range of studies have been performed that supplied insight in adaptive stress response and survival strategies.

**Objectives**

The objectives of this study are the assessment of *L. monocytogenes* population heterogeneity and the genotypic and phenotypic analysis of stress resistant variants obtained after high hydrostatic pressure, heat and acid exposure.

**Methods**

A range of phenotypes was determined for the different stress resistant variants obtained using *L. monocytogenes* EGDe, LO28 and ScottA, including level of acid resistance, growth rates at different temperatures, and biofilm-forming capacity. Whole genome sequencing analysis of *L. monocytogenes* wild types and selected stress resistant variants was performed, followed by cluster analysis of genotypic and phenotypic parameters to assess population diversity within *L. monocytogenes* strains.

**Conclusions**

Significant differences in phenotypes among variants were observed that pointed to differences in robustness and growth performance under food-relevant conditions. Whole genome sequencing analysis of *L. monocytogenes* wt and stress resistant variants revealed mutations in *ctsR*, encoding a class III heat shock repressor, and in *rpsU*, encoding ribosomal protein S21. Cluster analysis of genotypic and phenotypic parameters revealed large population diversity even within one *L. monocytogenes* strain and that different adverse conditions select for different variants. The large population diversity of *L. monocytogenes* signifies the organism's genetic flexibility, which in turn may contribute to the survival and persistence of this human pathogen in food-processing environments.

<sup>3</sup>Istituto di Microbiologia-Centro Ricerche Biotecnologiche, Università Cattolica del Sacro Cuore, Piacenza-Cremona, Italy

**Background**

Many lactic acid bacteria strains show extraordinary metabolic abilities, which are interesting for their application in functional food development such as group B vitamin overproduction. In this context, the determination of quality and food safety related traits i.e. antibiotic resistance are required.

**Objectives**

In this study, 29 *Lactobacillus plantarum* strains isolated from *chicha*, a traditional maize-based fermented Andean beverage, were previously selected by their ability to produce folic acid. Thus, we focused on evaluating additional activities relevant to functional food industry and to food safety and quality.

**Methods**

*Lactobacillus plantarum* strains were screened for riboflavin production (by reverse phase HPLC with fluorescence detector) and for the presence of riboflavin production related genes (*ribA*, *ribB*, *ribC*, *ribG* and *ribH*), antibacterial activity (Gaudana *et al.* 2010. *Brit J Nutr.* 103: 1620–1628) and antifungal activity (Magnusson *et al.* 2003. *FEMS Microbiol Lett.* 219:129-135). Regarding food safety, antibiotics resistance was tested as recommended by EFSA (2012) for *Lb. plantarum*.

**Conclusions**

Most strains strongly inhibited the growth of *Listeria innocua* CECT 910<sup>T</sup>, *Escherichia coli* CECT 5947, *Salmonella enterica* CECT 4138 and showed antifungal activity against *Aspergillus oryzae* CECT 2094. Some of them, inhibited *Aspergillus niger* CECT 2807, as well. Among them, four strains exhibited traits of interest for the functional food industry. They produced 400ng/ml riboflavin, determined by HPLC, and showed the amplification products corresponding to genes in the riboflavin synthetic pathway. All of these were sensitive to the antibiotics tested and were able to inhibit the growth of relevant food pathogens and spoiler fungi.

**Regulation of functional interferences between *Escherichia coli* type 1 fimbriae and Ag43 phase-variable adhesins**

J.M. Ghigo<sup>1</sup>

<sup>1</sup>*Department of Microbiology, Institut Pasteur, Paris, France*

Bacteria use a large number of adhesins involved in bacteria/surfaces and bacteria/bacteria interactions to colonize their environments. In *Escherichia coli*, there are two essential and prototypic adhesins: the chaperone-usher type 1 fimbriae, involved in mannose-dependent interactions to host cells, and the auto-transporter adhesin Ag43, mediating bacterial auto-aggregation. These two adhesins are regulated by two distinct phase variation mechanisms: a promoter recombination inversion for type 1 fimbriae and an epigenetic mechanism involving the Dam methylase and the oxidative stress regulator OxyR for the auto-transporter adhesin Ag43. Since expression of long type 1 fimbriae physically interferes with short Ag43 adhesins, the functions of these two adhesins are antagonistic, which raises the question of how *E. coli* coordinates their expression. I will describe previously unsuspected regulatory connection between phase variation mechanisms and stress responses and discuss how it contributes to coordinate the expression and exposition of *E. coli* surface adhesins and bacterial colonization capacity.

The process of biofilm dispersion represents an important phenotypic switch that allows cells residing within a biofilm to respond to changing conditions outside and within biofilm structures and to evade environmental stresses. Dispersion occurs in response to a wide array of signals, with dispersion-inducing conditions ranging from environmental cues to self-synthesized signaling molecules. Previous findings indicate biofilm dispersion by *Pseudomonas aeruginosa* to occur in response to various cues, to require BdlA and phosphodiesterases (PDEs, for instance DipA and RbdA), and to coincide with increased PDE activity and a reduction of c-di-GMP levels. However, little is known about dispersion cue sensing, the signaling events translating these cues into the modulation c-di-GMP levels, and the subsequent signaling cascade to enable dispersion resulting in the phenotypic switch. The presentation will focus on recent findings indicating how dispersion cue perception is translated across cellular compartments into the modulation of the intracellular c-di-GMP pool, the molecular events associated with signal transduction, and subsequent events associated with the induction of dispersion.

**ADHESIN PROTEINS IN BACILLUS CEREUS BIOFILMS.**

J. Caro-Astorga<sup>1</sup>, A. Perez-García<sup>1</sup>, A. de Vicente<sup>1</sup>, D. Romero<sup>1</sup>

<sup>1</sup>Microbiología, Facultad de Ciencias., Málaga, Spain

**Background**

The human pathogen *Bacillus cereus* is responsible for many recurrent outbreaks of food poisoning. Spores and biofilms are considered the most important reservoirs of *B. cereus* in contaminated fresh vegetables and fruits. Bacterial biofilms are difficult to eradicate specially due to the presence of a protective extracellular matrix made of exopolysaccharides, proteins, and other components. Amyloid-like proteins are essential for the integrity of biofilms of the related bacteria species *Bacillus subtilis*.

**Objectives**

To investigate the presence of amyloid-like fibers in biofilms of *B. cereus*.

**Methods**

We identified two genomic loci in *B. cereus*, which encode two orthologues of the amyloid-like protein TasA and a SipW signal peptidase of *B. subtilis*. Mutagenesis in *B. cereus* or heterologous expression of alleles in *B. subtilis* mutants combined with crystal violet staining served to evaluate the formation of biofilm. Electron microscopy let us visualize the presence of fibers on cells.

**Conclusions**

We demonstrate that the proteins TasA and CalY are necessary for *B. cereus* biofilm formation: i) as pellicle on the air-liquid interphase or ii) adhesion to abiotic surfaces. TasA and to a lesser extent CalY polymerizes in the form of fibers in the cell surface. Our findings of heterologous expression in *B. subtilis* let us propose an amyloid-like

nature of the *B. cereus* TasA-based fibers.

<sup>2</sup>Department of Biotechnology and Biomolecular sciences, University of New South Wales, Sydney, Australia

<sup>3</sup>School of Chemistry, University of New South Wales, Sydney, Australia

**Background**

Approximately 80% of Cystic Fibrosis (CF) patients are infected with *P. aeruginosa*. *P. aeruginosa* infected lungs/sputum of CF patients contain pyocyanin up to 27.3 µg/ml. Pyocyanin is a potent virulence factor causing cell death in chronic lung infection in CF patients, thus increasing mortality. Studies suggest that pyocyanin influence *P. aeruginosa* biofilm formation. However, no work was done investigating the mechanism or functions of pyocyanin in biofilm formation.

**Objectives**

To elucidate the mechanism and functions of pyocyanin in *P. aeruginosa* biofilm formation and identify a novel therapeutic target to modulate pyocyanin functions thereby control *P. aeruginosa* biofilm formation.

**Methods**

eDNA concentration in *P. aeruginosa* culture was measured using Qubit 2.0 flurometer. Pyocyanin-eDNA binding mechanisms were analysed using spectrometer techniques. Influence of pyocyanin-eDNA interaction on viscosity of DNA solution and cell surface of *P. aeruginosa* strains were analysed using viscometer and surface thermodynamics approach respectively. Biofilm imaging and analysis of biofilm properties were performed using confocal microscopy. Antioxidants interaction with pyocyanin and inhibition of pyocyanin-eDNA binding were investigated using NMR and spectrometer techniques respectively.

**Conclusions**

Pyocyanin promotes eDNA release in *P. aeruginosa* wild-type by inducing cell lysis mediated through generation of H<sub>2</sub>O<sub>2</sub>. Pyocyanin intercalates into the nitrogenous bases of DNA and consequently increases DNA viscosity and influences *P. aeruginosa* cell surface hydrophobicity, physico-chemical interactions promoting bacterial interaction and biofilm formation. Pyocyanin deficient strain showed significant reduction in eDNA release and biofilm formation. Ascorbic acid and glutathione modulate pyocyanin functions thus inhibit pyocyanin-eDNA binding and consequently hamper biofilm development.

#### BISTABLE GENE EXPRESSION IN SALMONELLA CONNECTS VIRULENCE TO PERSISTENCE

K.D. MacKenzie<sup>1</sup>, Y. Wang<sup>1</sup>, D.J. Shivak<sup>1</sup>, S. Lam<sup>1</sup>, H.G.G. Townsend<sup>1</sup>, W. Koester<sup>1</sup>, A. White<sup>1</sup>

<sup>1</sup>Vaccine and Infectious Disease Organization, University of Saskatchewan, Saskatoon, Canada

#### Background

For the human and animal pathogen *Salmonella* Typhimurium, biofilm formation is correlated with persistence outside a host but the connection to virulence is unknown.

#### Objectives

To analyze specialized cells of *S. Typhimurium* that arise from bistable expression of CsgD, the central biofilm regulator, during growth under biofilm-inducing conditions.

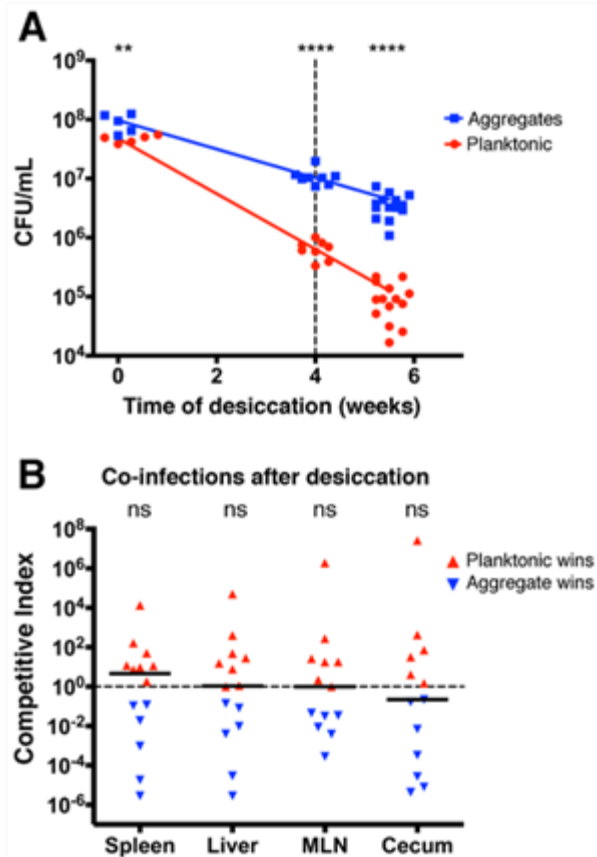

#### Methods

RNA-seq analysis of multicellular aggregates and planktonic cells identified 1856 genes, representing 34% of the genome, that were differentially expressed. Aggregated cells displayed the characteristic gene expression of biofilms, whereas

planktonic cells had enhanced expression of virulence genes, which were previously thought to be activated only by host conditions. Increased synthesis of the *Salmonella* pathogenicity island-1 type three secretion system in planktonic cells correlated with enhanced invasion of a human intestinal cell line and significantly increased virulence in mice as compared to the aggregates. However, when these same groups of cells were exposed to desiccation, the aggregates survived better and the competitive advantage of planktonic cells was lost.

## Conclusions

We hypothesize that CsgD-based differentiation is a form of bet-hedging for *S. Typhimurium*, with single cells primed for host cell invasion and aggregated cells adapted for persistence in the environment. This could be a common strategy for pathogens to spread the risks of transmission and ensure a smooth transition between the host and the environment.

### **GIL, A NEW C-DI-GMP-BINDING PROTEIN DOMAIN INVOLVED IN REGULATION OF CELLULOSE SYNTHESIS IN ENTEROBACTERIA**

X. Fang<sup>1</sup>, I. Ahmad<sup>2</sup>, A. Blanka<sup>2</sup>, M. Schotchkowski<sup>2</sup>, A. Cimdins<sup>2</sup>, M. Galperin<sup>3</sup>,  
U. Römling<sup>2</sup>, M. Gomelsky<sup>1</sup>

<sup>1</sup>Department of Molecular Biology, University of Wyoming, Laramie, USA

<sup>2</sup>Department of Microbiology Tumor and Cell Biology, Karolinska Institute, Stockholm, Sweden

<sup>3</sup>National Center for Biotechnology Information National Library of Medicine, National Institutes of Health, Bethesda, USA

### **Background**

Numerous enzymes are involved in c-di-GMP synthesis and degradation in enterobacteria. In contrast, only a handful of c-di-GMP receptors/effectors have been identified.

### **Objectives**

The aim of this study was to identify new c-di-GMP receptors and to further characterize them.

### **Methods**

In search of new c-di-GMP receptors, we screened the *Escherichia coli* ASKA overexpression gene library using the Differential Radial Capillary Action of Ligand Assay (DRaCALA) with fluorescently and radioisotope-labelled c-di-GMP. We uncovered three new candidate c-di-GMP receptors in *E. coli* and characterized one of them, BcsE.

### **Conclusions**

The *bcsE* gene is encoded in cellulose synthase operons in representatives of Gammaproteobacteria and Betaproteobacteria. The purified BcsE proteins from *E. coli*, *Salmonella enterica* and *Klebsiella pneumoniae* bind c-di-GMP via the domain of unknown function, DUF2819, which is hereby designated GIL, GGDEF I-site like domain. The RxGD motif of the GIL domain is required for c-di-GMP binding, similar to the c-di-GMP-binding I-site of the diguanylate cyclase GGDEF domain. Thus, GIL is the second protein domain, after PilZ, dedicated to c-di-GMP-binding.

We show that in *S. enterica*, BcsE is not essential for cellulose synthesis but is required for maximal cellulose production, and that c-di-GMP binding is critical for BcsE function. It appears that cellulose production in enterobacteria is controlled by a two-tiered c-di-GMP-dependent system involving BcsE and the PilZ domain containing glycosyltransferase BcsA.

**Host manipulation and bacterial survival Offered by Pathogens and Disease**

**Salmonella's intracellular toolkit**

D. Holden<sup>1</sup>

<sup>1</sup>MRC Centre for Molecular Bacteriology and Infection, Imperial College London, London, United Kingdom

Following entry of *Salmonella* into host cells, this pathogen resides in a membrane-bound compartment called the *Salmonella*-containing vacuole (SCV). Here, the bacteria sense the acidic pH and poor nutritional status of the vacuole lumen and either enter a viable non-replicating state or begin to divide. Replication is dependent on activation of the SPI-2 type III secretion system (T3SS). The T3SS comprises an envelope-spanning secretion system and associated translocon pore in the vacuolar membrane. Bacteria then sense the near-neutral pH of the host cell cytoplasm; this results in dissociation and degradation of a bacterial membrane-bound regulatory complex, which activates translocation of approximately 30 bacterial effector proteins into the host cell.

We are currently studying the biochemical and physiological functions of various effectors, which have been implicated in several activities, including lysosomal detoxification, SCV localisation and membrane dynamics, interference with immune signalling and the induction of cytotoxicity. In this talk I will discuss our recent progress in these areas.

**Manipulation of host membrane transport by Type IV effector proteins**

C. Roy<sup>1</sup>

<sup>1</sup>*Microbial Pathogenesis, Yale University School of Medicine, New Haven, USA*

Effector proteins delivered into the cytosol of host cells by Dot/Icm type IV secretion systems modulate processes important for creating a vacuole that supports bacterial intracellular replication. Here we describe the biochemical function of *Legionella pneumophila* and *Coxiella burnetii* effector proteins that play specific roles in controlling host membrane transport. These studies reveal new enzymatic activities and protein structures that demonstrate these pathogens encode novel effector proteins that can manipulate evolutionarily conserved host proteins that control membrane transport processes, which provide insight into how bacterial pathogens are able to construct a unique vacuole inside phagocytic host cells.

S Lyon UCBL, Lyon, France*

<sup>3</sup>*Evolutionary genetic and genomic,*

*Biometry and Evolutionary Biology UMR CNRS 5558, Villeurbanne, France*

**Background**

*Legionella pneumophila* is the causative agent of legionnaire's disease, a public health problem leading to at least 10% mortality rate. Via effectors secreted by its type IV secretion system, this intravacuolar bacterium interacts with many intracellular pathways of host cells including autophagy. This highly conserved pathway allows eukaryotic cells to recycle end-life cytosolic components in order to regulate cell homeostasis. Autophagy is also a degradative pathway essential to fight intracellular pathogen infections, but numerous microorganisms have evolved strategies in order to subvert this mechanism. The interaction between *L. pneumophila* and autophagy has been reported but remains still unclear.

**Objectives**

Our objective is to better decipher the *L. pneumophila*/autophagy interplay to determine whether this pathogen is controlled by autophagy or whether it gets benefit from this cellular process to survive/proliferate.

**Methods**

We used HeLa cells as a model to follow autophagy modulation upon *L. pneumophila* infection. Cells were infected with the northern Europe endemic strain *L. pneumophila* Paris.

**Conclusions**

Our experiments show that *L. pneumophila* infection induces autophagy in a type IV secretion system dependent manner, early post infection within infected cells but also in neighboring non-infected cells. Otherwise, preliminary data suggest that inhibition of autophagy is linked to a decreased bacterial replication, therefore autophagy could be beneficial for *L. pneumophila*. Thus, the autophagy stimulation could allow the acquirement of nutrients by the bacterium, provide membrane source for the expanding of *L. pneumophila* vacuole and/or lead to the delay of the fusion between *L. pneumophila* vacuole and lysosomes.

**PASTEURELLA MULTOCIDA TOXIN MANIPULATES T CELL DIFFERENTIATION**

K. Kubatzky<sup>1</sup>, D. Hildebrand<sup>1</sup>, K. Heeg<sup>1</sup>

<sup>1</sup>Department of Infectious Diseases, Medical Microbiology and Hygiene, Heidelberg, Germany

**Background**

*Pasteurella multocida* are gram-negative bacilli, which cause respiratory diseases in a number of wild and domestic animals. Toxigenic serotype A and D strains produce the *Pasteurella multocida* toxin (PMT), a classical AB toxin containing a deamidase activity in its catalytical domain. The toxin constitutively activates heterotrimeric G proteins and induces downstream signalling cascades involved in cytoskeleton rearrangement, proliferation, differentiation or survival of the host cell. Pathologically, PMT causes porcine atrophic rhinitis characterized by an increased number of osteoclasts and bone resorption at the nasal turbinate bones. However, PMT does not only act on cells of the bone system but we could demonstrate that it also modulates the signalling of many other hematopoietic cells such as B cells, macrophages or monocytes.

**Objectives**

We investigated how PMT treatment affects the differentiation of primary human T lymphocytes.

**Methods**

Proliferation studies showed that the toxin amplifies CD3/28 activated proliferation of T cells through the induction of cell cycle progression. Characterisation of transcription factor activation and the release of cytokines showed that PMT manipulates lineage determination towards T<sub>H</sub>17 and T<sub>reg</sub> cells as PMT-treated T cells are double positive for the lineage specific transcription factors FOXP3 (T<sub>reg</sub>) and RORγT (T<sub>H</sub>17) but predominantly behave like inflammatory IL-17-releasing T<sub>H</sub>17 cells.

**Conclusions**

These results indicate that a bacterial toxin is able to manipulate the direction of T<sub>H</sub>-cell differentiation and thereby presumably adjusts the sensitive balance of the immune response towards a condition that benefits the pathogen.

<sup>2</sup>Human Genetics, McGill University, Montreal, Canada

<sup>3</sup>Biotechnology Research Institute, National Research Council of Canada, Montreal, Canada

<sup>4</sup>Cytochem, Cytochem Inc, Montreal, Canada

**Background**

*Citrobacter rodentium* is a mouse pathogen widely used as a model for Enteropathogenic and Enterohemorrhagic *Escherichia coli* infections in humans. While *C. rodentium* causes self-limiting colitis in most inbred mouse strains, it induces fatal diarrhea in hyper-susceptible strains.

**Objectives**

Here we sought to identify the gene and molecular mechanisms underlying this differential response to intestinal infection.

**Methods**

We used a forward genetics approach to unambiguously localize the locus conferring this differential outcome to a 4 Mb interval. Systematic evaluation of the genes within this region pinpointed *R-spondin -2* as the gene underlying infection susceptibility.

**Conclusions**

Robust induction of *R-spondin -2* expression during infection in susceptible mouse strains leads to pathological activation of WNT signaling, subsequent loss of intestinal differentiation, and animal death. Conversely, mouse strains that do not induce *R-spondin -2* expression following infection undergo milder, self-limiting disease with no mortality. Our data demonstrate a previously unknown role of R-spondins and WNT signaling in susceptibility to infectious diarrhea and identify *R-spondin -2* as a key molecular link between enteric infection and control of intestinal homeostasis.

## **THE ROLE OF GLYCOGEN DEGRADATION AND METABOLISM IN BACTERIAL VAGINOSIS**

R. Hertzberger<sup>1</sup>, A. Lewis<sup>1</sup>, W. Lewis<sup>1</sup>

<sup>1</sup>*School of Medicine, Washington University, St. Louis, USA*

### **Background**

Bacterial vaginosis (BV) is a common condition of the human vagina in which the lactobacilli that normally dominate this niche are absent and replaced by a plethora of fastidious anaerobes. BV is associated with an increased risk of acquiring sexually transmitted disease and adverse health outcomes during pregnancy. Factors that drive the microbial dynamics in BV are poorly defined.

Glycogen is deposited in high levels in human vaginal epithelial cells. It has been postulated to be a major carbon source for vaginal bacteria.

### **Objectives**

Here we test the hypothesis that BV-associated bacteria digest and metabolize glycogen.

### **Methods**

We evaluated glycogen degrading enzyme activity in vaginal specimens of women with and without BV. Growth assays were conducted to examine the ability of lactobacilli and BV-associated bacteria to utilize glycogen. We examined evidence for glycogen-degrading enzymes among vaginal bacteria.

### **Conclusions**

These experiments provide strong evidence that BV associated bacteria degrade glycogen and metabolize the released sugar residues, whereas most vaginal lactobacilli do not utilize glycogen. These results provide an explanation of the recent observation by Mirmonsef et al. (1) that glycogen levels in BV are reduced.

1. Mirmonsef P, Hotton AL, Gilbert D, Burgad D, Landay A, Weber KM, Cohen M, Ravel J, Spear GT. 2014. Free glycogen in vaginal fluids is associated with Lactobacillus colonization and low vaginal pH. PLoS One. 9:e102467.

**Transcriptional networks controlling pathogenicity and polarized growth in *U. maydis***

B. Faist<sup>1</sup>, J. Ulrich<sup>1</sup>, K. Heimeß, J. Kämper<sup>1</sup>

<sup>1</sup>*Institute for Applied Biosciences, Karlsruhe Institute of Technology, Karlsruhe, Germany*

<sup>2</sup>*Institute for Microbiology and Genetics, University of Göttingen, Göttingen, Germany*

The transition from yeast-like saprophytic growth to the formation of pathogenic filamentous hyphae is a critical step in the life cycle of the basidiomycete *Ustilago maydis*. The switch is controlled by a pheromone/receptor system and the heterodimeric bE/bW transcription factor complex, encoded by the *a* and *b*-mating type loci, respectively. As both pathways control polar growth and cell cycle, they have to be closely interconnected and cross-controlled. The transcription factor Rbf1, a central node for gene regulation during pathogenic development, responds to inputs from both *a* and *b* pathways. Coordination is achieved via the interaction of Rbf1 and bW with the Clp1 protein that renders the bE/bW complex inactive and converts Rbf1 to a repressor of the pheromone pathway, releasing both the *a* and bE/bW mediated cell cycle arrest. We are currently investigating the molecular mechanisms by which the factors independently, cooperatively, and after interaction with Clp1, regulate gene expression during the dimorphic switch, using a combination of reporter gene assays, *in vitro* DNA binding studies and the genome-wide identification and occupation of promoter binding sites.

$\Delta clp1$  strains are capable to infect maize plants, but, as the cell cycle block is not released, development is stalled after formation of the appressorium, before the first cell division. In both wildtype and  $\Delta clp1$  hyphae, nuclear envelopes start to dissolve before appressorium formation, which is typical for nuclei entering mitosis. In wildtype cells, nuclei migrate into the invading hyphae and divide. However, nuclei of  $\Delta clp1$  cells remain in the appressorium, suggesting a novel function for Clp1 in the coordination of nuclear division and nuclear migration.

**Fungal plant pathogens**

**Pathogenomics of *Verticillium* wilt diseases**

B. Thomma<sup>1</sup>, M. Seidl<sup>1</sup>, X. Shi<sup>1</sup>, J. Boshoven<sup>1</sup>, M. van Damme<sup>1</sup>, J. Li<sup>1</sup>,  
E. Rojas Padilla<sup>1</sup>, Y. Song<sup>1</sup>, G. van den Berg<sup>1</sup>, L. Faino<sup>1</sup>

<sup>1</sup>Laboratory of Phytopathology, Wageningen University, Wageningen, Netherlands

Fungi cause severe crop losses and threaten food security worldwide. The soil-borne fungal pathogen *Verticillium dahliae* causes vascular wilt disease on hundreds of plant species, and disease control is challenging because resistance in plants is relatively rare. Moreover, *V. dahliae* has a flexible genome allowing it to escape host immunity and maintain aggressiveness. So far, knowledge on mechanisms governing this genomic flexibility remains limited.

Through comparative population genomics we have started to unravel mechanisms to establish the genomic diversity that is essential for adaptive genome co-evolution during the continued arms race with host plants. To this end, two *V. dahliae* genomes were assembled from telomere-to-telomere using long-read sequencing technology and optical mapping, and compared these to the genomes of other *Verticillium* spp., revealing a pre-speciation genome duplication event. Comparative genomics using the two finished *V. dahliae* genomes furthermore revealed recent segmental duplications that established lineage-specific regions. Interestingly, these regions are enriched for in planta-expressed effector genes encoding secreted proteins that enable host colonization, and thus contribute to the evolution of virulence. Our evidence suggests that error-prone homology-dependent DNA repair has caused genomic rearrangements, leading to extensive structural variations. Re-sequencing of additional strains showed that independent losses of genetic material favored the escape of host recognition and, likely, host specificity. We propose that evolution of *V. dahliae* is linked to segmental genome duplications mediated by improperly repaired DNA breaks.

In addition to genome evolution, we also study the role of epigenetic modifications on virulence of *V. dahliae* and the biological functions of effector proteins. Collectively, these research lines provide insight in mechanisms that make this fungus such a successful broad host range pathogen.

**Fungal plant pathogens**

**FGSSP6, A CERATO-PLATANIN PROTEIN WHICH CONTRIBUTES TO FUSARIUM GRAMINEARUM VIRULENCE ON WHEAT SPIKES.**

A.K.F.M. Machado<sup>1</sup>, W.S. Lee<sup>1</sup>, M. Urban<sup>1</sup>, F. Ölmez<sup>2</sup>, D.J. Studholme<sup>3</sup>, N.J. Talbot<sup>3</sup>, K.E. Hammond-Kosack<sup>1</sup>

<sup>1</sup>Plant Biology and Crop Science, Rothamsted Research, Harpenden, United Kingdom

<sup>2</sup>Plant Biology, Central Research Institute for Field Crops, Ankara, Turkey

<sup>3</sup>Bioscience, University of Exeter, Exeter, United Kingdom

**Background**

*Fusarium graminearum* (*Fg*) is one of the main fungal pathogens of wheat crops globally, causing Fusarium ear blight (FEB) disease. Like many other plant pathogens, *Fg* is predicted to produce *in planta* various secreted effector proteins that modulate plant metabolism to suppress or re-programme plant defences. These induced changes enable successful colonisation of plant tissues.

**Objectives**

To identify *Fg* effector proteins that can suppress host plant defences

**Methods**

We selected a set of small secreted proteins (SSP) to express *in planta* using the *Barley stripe mosaic virus* over-expression system (BSMV-VOX) and tested whether any enhance *Fg* fungal infection of susceptible wheat spikes.

**Conclusions**

Amongst the initial set of *Fg* SSP tested, one called FgSSP6, which belongs to the cerato-platanin protein (CPP) family, caused the quicker development of FEB disease symptoms in wheat ears following point inoculation. Bleaching of all spikelets on wheat spikes occurred by 12 days post inoculation (dpi) in the presence of BSMV:FgSSP6, whereas with various BSMV control vectors, full *Fg* infection took 16 dpi or longer. In several other plant pathogenic fungi, CPPs are already known to act as key virulence factors. So far our results suggest that FgSSP6 does not induce necrosis to assist infection, but either suppresses plant defence responses or plays a novel virulence role. This is the first report of the successful use of the BSMV-VOX system in combination with the *Fg*-wheat spike infections to identify novel

candidate *Fg* effectors. Further studies are planned to clarify the precise *in planta* role(s) of this newly identified cerato-platanin effector.

**A NOVEL METHOD FOR RAPIDLY ISOLATING FUNGAL SUPPRESSIVE MICROBES DIRECTLY FROM SOIL**

S. Cooper<sup>1</sup>, L. Pereg<sup>1</sup>

<sup>1</sup>Science and Technology, University of New England, Armidale, Australia

**Background**

Soilborne fungal root phytopathogens are some of the most damaging and difficult to control pathogens faced by agricultural production in the field, nurseries and greenhouses worldwide. There are many detrimental issues with current chemical control methods and this has increased interest in biological control using soil microorganisms that suppress the growth of phytopathogens. Antibiosis is one of the most important mechanisms responsible for fungal antagonism, with some significant antifungal compounds including, antibiotics, volatile organic compounds, hydrogen cyanide and lytic enzymes (Bhattacharyya & Jha, 2012; Compant *et al.*, 2005). Up to date methods for the isolation of fungal-suppressive microorganisms from the soil are time consuming and tedious.

**Objectives**

The aim of this study was to establish a simple method for isolating fungal pathogen-suppressive microbes (bacteria and fungi) directly from the soil as well as procedures for confirmation of disease suppression.

**Methods**

We will report on these methods, which were so far tested with three cotton fungal pathogens *Thielaviopsis basicola*, *Verticillium dahliae* and *Fusarium oxysporum* and a pathogen of button mushrooms *Verticillium fungicola*.

**Conclusions**

We have isolated a diversity of *T. basicola*- suppressive fungi and bacteria from two vastly different soil types. Identification of the antagonistic isolates revealed that they are a diverse lot, some belonging to groups known to be suppressive of a wide range of fungal pathogens, endorsing the power of this technique to rapidly and directly isolate soil-borne microbes antagonistic to a wide variety of fungal pathogens.

<sup>2</sup>*Institute of Agricultural Sciences,*

*Institute of Agricultural Sciences University of the Punjab Lahore Pakistan, LAHORE, Pakistan*

<sup>3</sup>*Department of Biosciences COMSATS Institute of Information Technology Islamabad Pakistan.,*

*Department of Biosciences COMSATS Institute of Information Technology Islamabad Pakistan., LAHORE, Pakistan*

**Background**

*Dalbergia sissoo* Roxburgi, (shisham) is an important and established forest species in south Asia. However, this precious tree is facing many devastating challenges from last six decades that dragging it towards disappearance from the subcontinent. Dieback is one of main diseases in Shisham plantations and caused by *Fusarium solani*.

**Objectives**

The aim of this study was to investigate the regional dependant genetic variation among different pathogenic *F. solani* isolates and a link to persistence cause of shisham dieback in various agro ecological zones.

**Methods**

A total of 23 pathogenic representative isolates of *F. solani*, collected from various agro ecological zones were subjected to analysis of genetic variability in terms of DNA polymorphism using RAPD-PCR. Results were obtained with the help of 10 randomly amplified polymorphic DNA markers (OPA1-OPA10) to test genetic variability in *F. solani* isolates.

**Conclusions**

A total of 238 amplified products generated with the primers and 23 isolates of *F. solani*. The pattern of genetic variability in the isolate was also supported by the analysis of the similarity indices and UPGMA dendrogram. Twenty three isolates of *F. solani* recovered from different areas showed a significant genetic variation during RAPD analysis. It seems that the genetic variability among fungal isolates is regional dependent and reason of persistent cause of shisham dieback in Punjab, Pakistan. Current findings showed the variation among pathogenic isolates of *F. solani* and

revealed that persistent cause of shisham dieback is due to *F. solani* complex in different shisham growing regions in province Punjab, Pakistan.

#### **APPLICATION OF TRICHODERMA STRAINS AGAINST GTD PATHOGENS**

C. Kovacs<sup>1</sup>, E. Sandor<sup>1</sup>, P. Balling<sup>2</sup>, Z. Bihar<sup>2</sup>, F. Peles<sup>1</sup>

<sup>1</sup>Food Sciences Institute, University of Debrecen, Debrecen, Hungary

<sup>2</sup>Research Institute for Viticulture and Oenology,  
Research Institute for Viticulture and Oenology, Tarcas, Hungary

#### **Background**

The Grapevine Trunk Diseases are one of the most prevalent diseases of the vineyard worldwide, caused by a variety of fungal pathogens. Mycoparasites, like *Trichoderma* species are potential biopesticides against GTD pathogens.

#### **Objectives**

The aims of this study were taxonomical identification of ten *Trichoderma* sps. from asymptomatic plants in the Tokaj wine region the determination of mycelial growth rate at different temperatures, the mycoparasitic potential against *Diplodia seriata* and *Neofusicoccum parvum* and field experiments with the mixed *Trichoderma* spore suspension.

#### **Methods**

The *Trichoderma* isolates were identified based on their ITS1,2 and *tef1* marker sequences. Their mycelial growth was determined from the two average colony diameters on PDA, measured for each *Trichoderma* isolates for 4 days. The mycoparasitic ability was detected according the method of Szerekes et al (2006; *Journal of Microbiological Methods*, 619-622). Some GTD symptomatic plants were treated with *Trichoderma* spore suspension in 2014. The treated trunks were checked monthly.

#### **Conclusions**

The ten isolates belonged to three species: *T. harzianum* (TR01-05, TR07, TR09-10), *T. orientalis* (TR06) and *T. viride* (TR08). The *Trichoderma* isolates showed different mycelial growth rate on different temperatures (5 - 37°C). The *T. orientalis* (TR06) and *T. harzianum* (TR05) isolates showed the highest growth rates within the whole temperature range, and their growth rates were especially high at 30 and 37°C. All *Trichoderma* overgrew the GTD pathogens, and sporulated on their colonies, therefore their Biocontrol Index was 100%.

The symptoms decreased on all treated samples, except one. Moreover the *Trichoderma* strains could be reisolated from their woody tissues.

**DNA substrates for horizontal gene transfer by natural transformation**

K.M. Nielsen<sup>1</sup>

<sup>1</sup>*Department of Life Sciences and Health,  
Oslo and Akershus University College (HIOA), Oslo, Norway*

The dynamic composition of the genomes of free-living bacteria challenges our understanding of microbial species. Horizontal gene transfer contributes to this dynamics and enables the ongoing dissemination of antimicrobial resistance genes across bacterial populations. Thus, there is a immediate need for a better understanding microbial genome dynamics both on a short-term ecological and long-term evolutionary scale. Natural transformation is a gene transfer mechanism that can both lead to intra-genomic rearrangement and inter-genomic DNA recombination. Here I present some recently experimentally derived results that advance our understanding of how species-foreign DNA fragments can be acquired by the naturally transformable model bacterium *Acinetobacter baylyi*, and describe the fate of such DNA after initial recombination with the host genome. Extracellular DNA in decaying organisms becomes chemically modified and degraded over time. However, it is known that from paleogenetics that short DNA fragments remain over time in some environments. The newly discovered opportunity for bacteria to acquire very short DNA fragments suggest extinct genomes can be an additional source of DNA for naturally transformable organisms.

**Evolution of a superbug: Real-time transfer of antimicrobial resistance in the host**

J.A. Lindsay<sup>1</sup>

<sup>1</sup>*Institute of Infection and Immunity, St George's University of London, London, United Kingdom*

***Staphylococcus aureus* is a commensal and major pathogen of humans and animals, capable of carrying a wide range of mobile genetic elements (MGEs) encoding antimicrobial resistance (AMR), virulence and host adaptation pathways. Whole genome analysis reveals a population structure consisting of independently evolving lineages, each defined by variation in core genomes. Within lineages, MGEs vary substantially with potential implications for selection in various hosts and under antimicrobial pressures. Little is known about the process of MGE transfer *in vivo*, nor how *S. aureus* adapt to antimicrobials or new hosts in real time. We co-colonized gnotobiotic piglets with both human- and pig-associated variants of the lineage clonal complex (CC)398, and observed transfer of MGEs including resistance genes from the pig to the human isolate within 4 hours. Extensive and repeated transfer resulted in colonization with isolates carrying a wide variety of MGE combinations. Whole genome sequencing of progeny bacteria revealed no acquisition of core genome polymorphisms. Separate studies of human hospitalized patients colonized with methicillin-resistant *S. aureus* (MRSA) CC22 revealed clonal populations varying in antimicrobial resistance profiles and MGE carriage, as well as free bacteriophage capable of gene transfer by generalized transduction. Our data show that transfer of AMR can occur at very high frequency *in vivo* and at higher frequency than detected *in vitro*.**

**Background**

Ethanol tolerance is a complex trait requiring interaction between different genes and pathways. Exposure to ethanol is toxic and slows down the cellular growth rate. Consequently, evolving high ethanol tolerance is slow and depends on the simultaneous occurrence of different mutations. This is unlikely in wild-type cells with a low mutation rate. In contrast, the odds that different mutations occur simultaneously are higher in hypermutable strains. These mutators are known to have an increased evolvability on a short evolutionary timescale, but display decreased fitness as the genetic load progressively becomes more deleterious.

**Objectives**

We aim at understanding the evolutionary mechanisms underlying adaptation to ethanol. This can lead to new insights that are also relevant for other complex phenotypes. Additionally, we investigate the role of a mutator phenotype in evolution towards high ethanol tolerance. This can shed light on the way bacteria adapt to severe stress conditions.

**Methods**

Here we used experimental evolution to study mechanisms underlying evolution to high ethanol tolerance in *E. coli*. Furthermore, through fluctuation assays and competition assays we determined mutation rates and established the advantage or disadvantage of hypermutation at different times during adaptive evolution.

**Conclusions**

We show that an increased mutation rate is essential for *E. coli* to adapt to high ethanol levels under slow-growing conditions. In direct competition under ethanol stress hypermutators outcompete wildtype cells. Moreover, we demonstrate that the population mutation rate decreases again when high ethanol tolerance is reached, indicating that once a population reaches a fitness peak, it strives to preserve the genome.

M.C. SALEH<sup>2</sup>, D. MAZEL<sup>2</sup>

<sup>1</sup>Génomes et Génétique, Institut Pasteur, Paris, France

<sup>2</sup>Department of Virology, Institut Pasteur, Paris, France

**Background**

The effects of gene order within the bacterial chromosome on cell physiology are poorly understood. *In silico* approaches have showed that ribosomal protein genes locate near the replication origin (*oriC*) in fast-growing bacteria, suggesting that such a positional bias is an evolutionarily conserved growth-optimization strategy. *Vibrio cholerae*, a bi-chromosomal fast-growing pathogen is a well-characterized model organism to experimentally tackle this hypothesis. The *S10-spc-α* locus (S10) encodes half of the ribosomal protein genes and is conserved along all life forms.

**Objectives**

To relocate S10 to different positions along the genome and measure putative physiological effects.

**Methods**

We used novel recombineering tools to create a set of isogenic strains in which S10 was systematically relocated to alternative genomic positions. Their DNA and RNA was analyzed using NGS.

**Conclusions**

We show that S10 relative distance to the *oriC* tightly correlates with a reduction of its dosage, mRNA abundance and growth rate. This is accompanied by a significant reduction in host-invasion capacity of *Drosophila melanogaster*. Strains bearing two S10 copies far from *oriC* rescue both phenotypes demonstrating that replication-dependent gene-dosage reduction is the main mechanism behind these alterations. Deep sequencing analyses shows that i) the whole *oriC* region is less transcribed in the most affected derivatives and ii) Gene Set Enrichment Analyses reveal 'translation' as the most altered pathway in such derivatives. S10 positioning connects genome structure to cell physiology in *V. cholerae*. We show that genomic positioning of genes involved in the flux of genetic information conditions global growth and hence bacterial physiology and evolution.

## **EVOLUTION AND PATHOADAPTATION OF PSEUDOMONAS AERUGINOSA IN CYSTIC FIBROSIS PATIENTS**

R.L. Marvig<sup>1</sup>, L.M. Sommer<sup>2</sup>, S. Molin<sup>2</sup>, H.K. Johansen<sup>3</sup>

<sup>1</sup>Center for Genomic Medicine and Dept. of Clinical Microbiology, Rigshospitalet Copenhagen University Hospital, Copenhagen, Denmark

<sup>2</sup>Systems Biology, Technical University of Denmark, Copenhagen, Denmark

<sup>3</sup>Clinical Microbiology, Rigshospitalet Copenhagen University Hospital, Copenhagen, Denmark

### **Background**

Laboratory evolution experiments have led to important findings addressing to what extent natural selection constrains parallel evolving organisms to follow common evolutionary pathways towards adaptive phenotypes, and in which way evolutionary outcomes become intertwined over time such that future alternatives may be contingent on the prior history of an evolving population. Nonetheless, similar systematic investigations of bacterial populations living in complex natural environments are lacking, limiting our understanding of these processes in situ.

### **Objectives**

To address questions about the role of evolutionary convergence and historical contingency in a “natural evolution experiment”, we investigate the molecular evolution of distinct clonal lineages of *Pseudomonas aeruginosa* from the initial invasion into the cystic fibrosis (CF) airways and onwards as they genetically adapt to a human host after transition from their environmental habitat.

### **Methods**

We sequenced and analyzed the genomes of >500 longitudinally collected clinical isolates of *P. aeruginosa* sampled from >40 CF patients.

### **Conclusions**

Parallel evolution across multiple *P. aeruginosa* strains identified convergent molecular evolution in pathoadaptive genes that revealed host-adaptation to involve remodeling of regulatory networks and central metabolism, acquisition of antibiotic resistance, and loss of extracellular virulence factors. Furthermore, we demonstrated how historical contingency played a role in on the evolution of regulatory networks, in which mutations in downstream transcriptional regulators were contingent upon mutations in upstream regulators; suggesting that remodeling of regulatory networks facilitate adaptation. Knowledge of pathoadaptive mutations and evolutionary contingency may help prediction of bacterial evolution in CF patients and design of future intervention strategies.

**Mäkelä-Cassell Awardee: Taxon-specific growth rates are related to phylogeny in soil bacterial communities**

E. Morissey<sup>1</sup>, R.L. Mau<sup>1</sup>, E. Schwartz<sup>1</sup>, J.G. Caporaso<sup>2</sup>, P. Dijkstra<sup>1</sup>, N. van Gestel<sup>1</sup>, B.J. Koch<sup>1</sup>, C.M. Liu<sup>3</sup>, T.A. McHugh<sup>1</sup>, J.C. Marks<sup>1</sup>, L.B. Price<sup>3</sup>, B.A. Hungate<sup>1</sup>

<sup>1</sup>Center for Ecosystem Science and Society, Northern Arizona University, Flagstaff, USA

<sup>2</sup>Department of Biological Sciences, Northern Arizona University, Flagstaff, USA

<sup>3</sup>TGEN, Translational Genomics Research Center, Flagstaff, USA

Understanding if and how the phylogenetic composition of microbial communities is related to ecosystem function has been a central question in microbial ecology. To date, attempts to unambiguously identify the microbial taxa involved in an ecosystem process of interest have relied on stable isotope probing (SIP), where heavy isotopes are incorporated into the nucleic acids of microorganisms utilizing a compound of interest (<sup>13</sup>C carbon sources) or actively growing (<sup>18</sup>O water). Traditionally, this method has been qualitative. However, we have advanced this technique in order to quantitatively assess the amount of isotope incorporation into nucleic acids of specific taxa. This is achieved by comparing the naïve density of a DNA fragment to its density after incubation in the presence of a stable isotope, as the change in density is proportional to the amount of stable isotope incorporation. Using this technique, we have estimated the taxon-specific growth rates of soil bacteria under control conditions and in the presence of an added substrate (<sup>13</sup>C-glucose). The growth rates and <sup>13</sup>C assimilation rates of the most abundant taxa were compared to their phylogenetic relatedness to determine if there was a phylogenetic signal (measured using Blomberg's K test) associated with the growth response. Indeed, closely related organisms were similar in their growth responses. This phylogenetic signal was found after single (K=0.81, p<0.001) and repeated substrate addition (K=0.99, p<0.001), as well as in the absence of added substrate (K=0.73, p<0.001). The different resource conditions elicited growth of distinct, phylogenetically-clustered groups suggesting a microorganism's taxonomic identity could be a useful indicator of its ecology in the environment. Generally, these data suggest that the growth responses and therefore nutrient transformations of soil microorganisms are significantly influenced by evolutionary history.

**Antibiotics: novel approaches to treat resistant organisms**

**Compounds for Overcoming Antibiotic Tolerance and Resistance**

K. Lewis<sup>1</sup>

<sup>1</sup>*Biology, Northeastern University, MA, USA*

**Compounds for Overcoming Antibiotic Tolerance and Resistance**

Currently available antibiotics are largely inactive against dormant persister cells produced by microbial pathogens, and are prone to resistance development. Persisters are responsible for the chronic, relapsing nature of the disease. An even more daunting unsolved problem is the seemingly inevitable development of resistance to all known antibiotics. We find that different natural compounds targeting the Clp protease, acyldepsipeptide and lassomycin, kill persisters and eradicate the pathogen population. Teixobactin, a cell wall synthesis inhibitor was discovered in a screen of uncultured soil bacteria. Teixobactin is the first member of a new class of cell wall acting inhibitors and binds two targets, lipid II, precursor of peptidoglycan, and lipid III, precursor of wall teichoic acid. The targets are not proteins, and there is no resistance development to this compound. Soil microorganisms are likely to harbor many more sterilizing and largely resistance-free compounds. Screening uncultured bacteria provides an effective platform for antibiotic discovery.

**FEMS-1059**

**Antibiotics: novel approaches to treat resistant organisms**

**Exploring microbial natural products as sources for novel antibiotics**

O. Genilloud<sup>1</sup>

<sup>1</sup>-, *Fundación MEDINA, Granada, Spain*

Infectious diseases are one of the leading causes of death worldwide and the emergence of multi-drug-resistant bacteria, and the lack of new antibiotics in development with new modes of action are widely accepted as one of the major clinical concerns that require to be addressed from the public and private sectors. One of major clinical needs are related with MDR Gram-negative bacteria hospital-acquired infections, frequently associated with high mortality rates and few treatment options. Very limited options have been developed to date against Gram negative, and even last resorts antibiotics such as colistin and polymixin B are facing resistances.

Microbial natural products (NPs) have been one of the most prolific sources of new leads for the discovery of novel antibiotics, with a large number of compounds and analogs successfully introduced in the market in the past decades and still today in the clinic. NPs potency and selectivity is the result of an extended evolutionary selection to create biologically active molecules with the required properties to penetrate bacterial membranes and interact and potentially inhibit bacterial targets.

The strategy developed atMEDINA for the discovery for novel antibiotics is focused on the exploitation of our proprietary NPs collections, one of the most diverse and continuously expanding sources of novel compounds. Most recent efforts have permitted the identification of novel families of compounds that will be discussed in the context of current antibiotic discovery efforts in the academia and the pharma sector.

**Antibiotics: novel approaches to treat resistant organisms**

**Xenorhabdus & Photorhabdus: a Promising Bioresource for the Discovery of Novel Antibiotics**

P. Villain-Guillot<sup>1</sup>

<sup>1</sup>, Nosopharm, Nimes, France

Antibiotic resistance remains a high unmet medical need. The situation is worsened by the scarcity of investigational new drugs in the antibacterial pipeline, especially against multidrug-resistant Gram-negative pathogens (*Enterobacteriaceae*, *Pseudomonas aeruginosa*, *Acinetobacter baumannii*). Novel antibiotic classes are clearly needed to overcome the current mechanisms of resistance faced by the clinicians. Among the different approaches to discover novel antibacterial classes, the mining of the microbial biodiversity is one of the most promising. In this context, the bacterial genera *Xenorhabdus* and *Photorhabdus* represent a high-potential bioresource that remains to be extensively explored. *Xenorhabdus* and *Photorhabdus* are symbiotic bacteria of the entomopathogenic nematodes *Steinernema* and *Heterorhabditis*. They have an original life-cycle that requires the production of a great diversity of bioactive secondary metabolites, including antimicrobials. This ecological rationale is supported by a high content of PKS and NRPS genes in their genomes. The screening of a collection of *Xenorhabdus* and *Photorhabdus* strains led to the discovery of the Odilorhabdins, a novel antibiotic class with a broad spectrum activity against Gram-positive and Gram-negative pathogens, including multidrug-resistant clinical strains. The Odilorhabdins have shown efficacy in murine infection models. They are currently undergoing preclinical optimization by medicinal chemistry. Odilorhabdins are expected to enter into clinical trials in human by 2017.

**Antibiotics: novel approaches to treat resistant organisms**

**$\beta$ -Hairpin peptidomimetic antibiotics targeting outer membrane proteins in Gram-negative bacteria**

J.A. Robinson<sup>1</sup>

<sup>1</sup>Chemistry, University of Zurich, Zurich, Switzerland

The biogenesis of the asymmetric outer membrane (OM) of Gram-negative bacteria, with lipopolysaccharide in the outer leaflet and phospholipid in the inner leaflet, and adorned with lipoproteins and a large family of  $\beta$ -barrel OM proteins, is an attractive target for the development of new antibiotics. One approach focuses on naturally occurring cationic antimicrobial host defense peptides (HDPs), which form part of innate immunity in many organisms and provide a first line of protection against microbial infection. In the pharmaceutical sciences as a whole it is well known that when linear peptides are constrained into unique backbone conformations, peptidomimetics can sometimes be found with target specificity and affinity not seen with unconstrained peptides. As an example, I will describe in this lecture a family of constrained  $\beta$ -hairpin-shaped cationic antimicrobial peptidomimetics derived from a HDP, with potent and selective antimicrobial activity against *Pseudomonas* spp. These peptidomimetics were shown to target the  $\beta$ -barrel outer membrane protein LptD in *P. aeruginosa* and to inhibit its key function in LPS transport during outer membrane biogenesis. This represents a novel mechanism of action that has not been described so far in any naturally occurring HDP or antimicrobial natural product. A clinical candidate is now in phase-II clinical studies in patients with serious hospital-acquired lung infections.

**Cyclic di-nucleotides in bacteria**

## **C-DI-GMP SIGNALING AND E. COLI BIOFILM ARCHITECTURE**

R. Hengge<sup>1</sup>

<sup>1</sup>*Institute of Biology / Microbiology, Humboldt-Universität zu Berlin, Berlin, Germany*

### **Background**

Bacterial biofilms contain matrix-producing and matrix-free cells in distinct zones. In *E. coli* K-12 the production of matrix components such as amyloid curli fibres and cellulose is promoted by the second messenger c-di-GMP, which is synthesized by 12 diguanylate cyclases (DGC) and degraded by 13 phosphodiesterases (PDE). Two PDE/DGC pairs (YhjH/YegE and YciR/YdaM) constitute a bistable switch device that can sharply drive up the cellular c-di-GMP level in slowly growing and stationary phase zones of macrocolony biofilms and thereby turn on the expression of the biofilm regulator CsgD. This transcription factor then activates expression of the curli genes as well as of *yaiC*, which encodes a DGC specifically required for cellulose synthesis.

### **Objectives**

Recent progress in understanding this c-di-GMP signaling network will be presented.

### **Methods**

Genetics, biochemistry, microscopy, mathematical modelling.

### **Conclusions**

In the central c-di-GMP signaling network that controls *E. coli* biofilm matrix production, YegE is the 'starter' DGC, which - by producing c-di-GMP that is sensed by the 'trigger enzyme' YciR - promotes YdaM activity and YaiC expression. These two DGCs further increase c-di-GMP levels and thereby form a positive feedback loop. In addition, most of the other DGCs and PDEs are expressed but do not contribute to this scenario under standard conditions, suggesting that these enzymes are inactive. However, specific signals perceived by the various N-terminal sensor domains may activate these DGCs and PDEs and thereby modulate c-di-GMP levels, matrix production and biofilm morphology. As an example a novel subfamily of c-di-GMP-related enzymes will be presented whose activity is regulated by redox signal input.

**c-di-AMP signalling in *Staphylococcus aureus***

A. Gründling<sup>1</sup>, I. Campeotto<sup>1</sup>, Y. Zhang<sup>1</sup>, M. Mladenov<sup>1</sup>, P.S. Freemont<sup>2</sup>

<sup>1</sup>Section of Microbiology and MRC Centre for Molecular Bacteriology,  
Imperial College London, London, United Kingdom

<sup>2</sup>Section of Structural Biology, Imperial College London, London, United Kingdom

Signalling nucleotides are key molecules in all domains of life and control fundamental processes including central metabolic or stress response processes as well as biofilm formation. c-di-AMP is one of the more recently discovered signalling molecules and is produced by a number of bacteria including pathogens such as *Staphylococcus aureus*. In *S. aureus*, c-di-AMP is synthesised from two molecules of ATP by the diadenylate cyclase DacA and degraded to pApA by the phosphodiesterase GdpP. c-di-AMP has since been implicated in controlling cell size in *S. aureus*, in helping this microorganism cope with cell wall stress and in the regulation of potassium uptake. Here, the identification and function of c-di-AMP receptor proteins will be discussed. Furthermore, the apo- and c-di-AMP complex structures of PstA, one of the c-di-AMP target proteins, will be presented. This allowed us to propose a mechanism on how PstA functions as a signaling transduction protein. The complex structure also highlighted common features of c-di-AMP binding sites allowing for a more rational prediction of cyclic-di-AMP binding sites.

### Cyclic di-nucleotides in bacteria

#### **Chp8, a composite diguanylate cyclase which promotes *Pseudomonas syringae* pv tomato DC3000 pathogenicity and plant immune evasion during infection of *Arabidopsis thaliana***

C. Engl<sup>1</sup>, C.J. Waite<sup>1</sup>, J.F. McKenna<sup>2</sup>, M. Bennett<sup>1</sup>, T. Hamann<sup>3</sup>, M. Buck<sup>1</sup>

<sup>1</sup>Life Sciences, Imperial College London, London, United Kingdom

<sup>2</sup>Biological and Medical Sciences, Oxford Brookes University, Oxford, United Kingdom

<sup>3</sup>Biology, Norwegian University of Science and Technology, Trondheim, Norway

*Pseudomonas syringae* (*Ps*) is a bacterial pathogen which interacts with more than 50 different plants causing diseases in crops including tomato, beans and rice. The associated decrease in crop yields results not only in economic losses, but also threatens global food security. *Ps* uses type-three-secretion (TTSS) to deliver virulence factors into the plant that promote survival of the bacterium and ultimately results in disease symptoms. The *Ps* TTSS is a product of the *hypersensitive response and pathogenicity* (*hrp*) and *hypersensitive response and conserved* (*hrc*) gene cluster under the control of sigma<sup>54</sup>, the co-dependent transcriptional activators HrpRS and the alternative sigma factor HrpL.

Here, I will present our findings that in the model strain *Ps* DC3000 HrpRS also activate expression of the composite diguanylate cyclase Chp8 (Co-regulated with hrp 8) in response to plant derived signals. Chp8 diminishes the hormonal immune response of *Arabidopsis thaliana* and promotes *Ps* DC3000 pathogenicity. Chp8 is the first example of a diguanylate cyclase promoting pathogenicity of a bacterial plant pathogen. The study was recently published in *mBio* (Engl *et al.*, 2014) and appraised as the first complete description of how a diguanylate cyclase can affect bacterial-host interactions in an acute infection model.

**THE ROLE OF CYCLIC DI-GMP IN STREPTOMYCES DEVELOPMENT**

N. Tschowri<sup>1</sup>, M.A. Schumacher<sup>2</sup>, S. Schlimpert<sup>3</sup>, N.B. Chinnam<sup>2</sup>, R.G. Brennan<sup>2</sup>,  
M.J. Buttner<sup>3</sup>

<sup>1</sup>Molecular Microbiology, Humboldt University Berlin, Berlin, Germany

<sup>2</sup>Biochemistry, Duke University School of Medicine, Durham, USA

<sup>3</sup>Molecular Microbiology, John Innes Centre, Norwich, United Kingdom

**Background**

*Streptomyces* are non-motile soil bacteria with a unique mycelial, sporulating life cycle and the ability to produce highly valuable secondary metabolites. *Streptomyces venezuelae* encodes for 10 putative cyclic di-GMP-metabolizing enzymes but the cellular processes controlled by the cyclic di-nucleotide remained elusive.

**Objectives**

Aiming to gain more knowledge about the regulation of the developmental processes in *S. venezuelae*, we found that elevated levels of c-di-GMP lead to a pronounced delay of the developmental program. On the other hand, depletion of c-di-GMP results in an enhanced sporulation phenotype due to bypassing the aerial mycelium stage.

**Methods**

We applied a global pull-down approach using the c-di-GMP Capture Compound (Caprotec, Berlin) and found a c-di-GMP-responsive regulator that connects c-di-GMP signalling pathways and developmental processes in *S. venezuelae*. Using structural and biochemical analyses we identified a previously unseen oligomeric form of c-di-GMP, which enables the effector protein to dimerize by binding to a heretofore unknown binding motif.

**Conclusions**

Altogether, we demonstrate that the signalling molecule c-di-GMP controls the hypha-to-spore transition in filamentous bacteria.

## **Bacterial persistence and Toxin - Antitoxins**

### **Magic Spot Controls Bacterial Persister Cell Formation by Activating Toxin - Antitoxins**

K. Gerdes<sup>1</sup>, E. Maisonneuve<sup>1</sup>, K. Winther<sup>1</sup>, E. Germain<sup>1</sup>, M. Roghanian<sup>1</sup>,  
R. Jørgensen Bager<sup>1</sup>, M. Fazli<sup>1</sup>

<sup>1</sup>Department of Biology, University of Copenhagen, Copenhagen, Denmark

#### **Background**

We showed previously that multidrug tolerance (persistence) of the model organism *Escherichia coli* K-12, depends stochastic induction of Toxin - Antitoxin (TA) activity by (p)ppGpp in a regulatory cascade that included also Lon protease and polyphosphate (Maisonneuve et al., **Cell**, 154, 1140-50, 2013). The TAs involved all encode inhibitors of translation, such as RelE, MazF, HicA etc. Remarkably, all antitoxins of *E. coli* K-12 encoded by type II TA loci are degraded by Lon that, in turn, is activated by polyphosphate. The model explaining stochastic induction of persistence is shown in **Figure 1**. Sophie Helaine and David Holden (Imperial College London, UK) showed that a similar mechanism allows cells of *Salmonella* to survive antibiotic treatment within macrophages (**Science** 343, 204–208, 2014).

#### **Objectives**

Many bacterial pathogens contain multiple type II TA genes and rely on (p)ppGpp to be virulent (**Figure 2**). We will determine the role(s) that (p)ppGpp and TAs play in persistence and virulence of different bacterial pathogens, including, *Mycobacterium tuberculosis*, *Burkholderia cenocepacia* and *Photobacterium luminescence*.

#### **Methods**

In this work, we will employ physiological, genetic, cytological and biochemical methods to reach our aim.

#### **Conclusions**

Preliminary results indicate that indeed (p)ppGpp is required for persistence of bacterial pathogens.

**FEMS-3162**

**Bacterial persistence and Toxin - Antitoxins**

**FIC domains in *Bartonella*: Evolution of diversified host effectors from a widely-spread bacterial toxin/antitoxin system**

C. Dehio<sup>1</sup>

<sup>1</sup>Biozentrum, University of Basel, Basel, Switzerland

The FIC domain being present in thousands of proteins and found in all domains of life mediates post-translational modification of target proteins, typically by transfer of an AMP moiety from ATP onto a target tyrosyl or threonyl side chain by a process called AMPylation or adenylation. The alpha-proteobacterial genus *Bartonella* comprises facultative intracellular pathogens that utilize a VirB type IV secretion system to translocate a cocktail of bacterial effectors protein into host cells in order to subvert cellular function to the benefit to the bacterial intruder. Diversified copies of the FIC domain are prominently presented in these effector sets, indicating that the various FIC domain variants may mediate diverse effector functions during infection. I will discuss the evolutionary origin of the FIC domain as a bacterial toxin-antitoxin system, its fusion with a type IV secretion signal to constitute an ancestral translocateable effector, as well as the duplication and diversification of the ancestral effector gene in the course of the evolution of the effector cocktails that facilitate host cell infection by bartonellae in diverse mammals.

**FEMS-0655**

**Bacterial persistence and Toxin - Antitoxins**

**Novel regulatory mechanisms in toxin-antitoxin modules**

R. Loris<sup>1</sup>

<sup>1</sup>*Structural Biology Brussels, Vrije universiteit brussel, Brussel, Belgium*

Prokaryotic toxin-antitoxin modules are involved in the establishment of persister cells. The latter involves complex regulatory mechanisms that link the regulation of protein activity to regulation of transcription. Recent structural and biochemical data shows a plethora of molecular mechanisms to achieve this goal. In the *phd/doc* module, conditional co-operativity is established via a combination of negative co-operativity through entropic exclusion of and IDP domain combined with a low to high affinity switch for the interaction between toxin and antitoxin. While Doc stabilizes the DNA binding conformation of Phd, Phd likewise inhibits the kinase activity of Doc and simultaneously prevents misfolding of Doc. The same phenomenon of conditional co-operativity is observed for *mazEF* and *ccdAB*, but with a different structural basis, although intrinsic disorder in the antitoxin is a common theme. Other TA modules such as *higBA* are regulated through a seemingly more simple mechanism where the antitoxin acts as the sole repressor, while toxin significantly weakens operator binding. Such a mechanism is observed in several *higBA* modules as well as in *mqsRA* and allows for transcription regulation without the specific need of intrinsic disorder.

**Bacterial persistence and Toxin - Antitoxins**

**Chaperone-mediated control of toxin-antitoxins**

P. Bordes<sup>1</sup>, A. Sala<sup>1</sup>, N. Slama<sup>1</sup>, P. Texier<sup>1</sup>, A.M. Cirinesi<sup>1</sup>, P. Genevoux<sup>1</sup>

<sup>1</sup>Laboratoire de Microbiologie et Génétique Moléculaires, CNRS Université Paul-Sabatier, Toulouse, France

Bacterial toxin-antitoxin systems are stress-responsive elements generally composed of a stable toxin that forms an inactive complex with its less stable cognate antitoxin. In response to specific stress conditions the antitoxin is degraded by stress proteases and the free active toxin subsequently targets important cellular processes such as DNA replication or protein synthesis. It is believed that the resulting growth inhibition facilitates adaptation to stress and persistence. *Mycobacterium tuberculosis*, the causing agent of human tuberculosis, encodes 79 putative toxin-antitoxin systems and it has been proposed that persistence induced by active toxins might be relevant for its pathogenesis. The tripartite toxin-antitoxin-chaperone (TAC) system of *M. tuberculosis* is an atypical toxin-antitoxin system strongly induced in persisters and tightly controlled by the molecular chaperone Rv1957, which is related to the canonical SecB chaperone involved in Sec-dependent protein export in Gram negative bacteria. Indeed, in spite of very little sequence similarity, Rv1957 is able to efficiently replace SecB during protein export in *E. coli*, and to specifically control the functional HigB1-HigA1 toxin-antitoxin system of *M. tuberculosis*. How does the mycobacterial SecB-like chaperone respond to stress and control the toxin activation cascade, and to what extent such activation is important for *M. tuberculosis* persistence and virulence are so far unresolved questions.

In this work, we will present recent data concerning the molecular mechanism of TAC complex formation and toxin activation, with emphasis on the role played by the SecB-like chaperone.

**CRISPR - biological and technological advances**

**Type II CRISPR-Cas9 systems: mechanisms, evolution and applications**

E. Charpentier<sup>1</sup>

<sup>1</sup>*Regulation in Infection Biology, Helmholtz Centre for Infection Research, Braunschweig, Germany*

The RNA-programmable CRISPR-Cas9 system has recently emerged as a transformative technology in biological sciences, allowing rapid and efficient targeted genome editing, chromosomal marking and gene regulation. In this system, the endonuclease Cas9 or catalytically inactive Cas9 variants are programmed with single guide RNAs (sgRNAs) to target site-specifically any DNA sequence of interest given the presence of a short sequence (Protospacer Adjacent Motif, PAM) juxtaposed to the complementary region between the sgRNA and target DNA. The system is efficient, versatile and easily programmable.

Originally, CRISPR-Cas is an RNA-mediated adaptive immune system that protects bacteria and archaea from invading mobile genetic elements (phages, plasmids). Short crRNA (CRISPR RNA) molecules containing unique genome-targeting spacers commonly guide Cas protein(s) to invading cognate nucleic acids to affect their maintenance. CRISPR-Cas has been classified into three main types and further subtypes. CRISPR-Cas9 originates from type II CRISPR-Cas that has evolved unique molecular mechanisms for maturation of crRNAs<sup>a</sup> and targeting of invading DNA<sup>a,b</sup>, which we identified in the human pathogen *Streptococcus pyogenes*. On the basis of the discovery of the DNA targeting mechanism, we proposed that RNA-programmable Cas9 could offer considerable potential for genome editing in cells of the three kingdoms of life for biotechnological, biomedical and gene-therapeutic purposes<sup>b</sup>. As demonstrated by a large number of studies published in the last 18 months, DNA targeting by CRISPR-Cas9 has quickly been adopted by the scientific community to edit and silence genomes in a large variety of cells and organisms including human cells, plants and mice. I will discuss the biological roles of CRISPR-Cas9, the mechanisms involved, the evolution of type II CRISPR-Cas components in bacteria and the applications of CRISPR-Cas9 as a novel genome engineering technology.

**Specific nucleic acid targeting by the Type III CRISPR-Cas complexes**

J. van der Oost<sup>1</sup>

<sup>1</sup>Laboratory of Microbiology, Wageningen University, Wageningen, Netherlands

CRISPR-Cas is a prokaryotic adaptive immune system that provides sequence-specific defense against foreign nucleic acids. Comparative analysis has revealed at least 3 distinct types of CRISPR-Cas systems. During the past few years, much has been learned on the structures and mechanisms of the effector complexes of Type I (Cascade) and Type II (Cas9). Until recently, structural and functional insights on the effector complexes of Type III CRISPR-Cas systems has lagged behind. To address this, the Type III-A (Csm) and III-B (Cmr) complexes of *Thermus thermophilus* have been selected as model systems. Integrated structural analyses (MS, EM) have revealed that the overall architecture of both complexes strongly resembles that of the Type I Cascade complexes. TtCsm is composed of five different protein subunits (Csm1-Csm5), whereas TtCmr has six subunits (Cmr1-Cmr6). Like Cascade, both Type III complexes have an uneven stoichiometry and a single crRNA guide. Interestingly, the TtCsm crRNA content is similar to the Type III-B Cmr complex, indicating that crRNAs are shared among different subtypes. Unexpectedly, both TtCmr and TtCsm cleave complementary target RNAs at multiple sites. Outstanding questions of the *Thermus* Type III systems include (i) a motif for auto-immunity protection (PAM analog), (ii) some target quality control (seed analog), and (iii) last but not least the potential of RNA-guided DNA targeting. The latest insights in the TtCsm and TtCmr mechanisms will be discussed.

**Memory formation in E. coli CRISPR-Cas systems**

S.J.J. Brouns<sup>1</sup>

<sup>1</sup>*Laboratory of Microbiology, Wageningen University, Wageningen, Netherlands*

An adaptive immune system in prokaryotes called CRISPR (clustered regularly interspaced short palindromic repeats) uses small guide RNAs to neutralize invading viruses and plasmids. In *Escherichia coli*, immunity depends on a ribonucleoprotein complex called Cascade. This protein complex recognizes double-stranded DNA from invaders by forming basepairs between the guide RNA and invader DNA. The structure of Cascade displays an unusual seahorse-shape that binds target DNA in an unique underwound ribbon like duplex. This recruits the effector nuclease Cas3 which progressively degrades the target DNA in an ATP-dependent manner, neutralizing the virus infection. Apart from giving insight into the crystal structure and function of Cascade, I will also show how viruses are able to escape immunity by point mutagenesis, and unveil how hosts rapidly adapt their immune specificity making use of prior memories to effectively counter escape mutants.

### **Establishment of the fungal mycelium**

#### **Heterogeneity of the fungal mycelium**

H.A.B. Wösten<sup>1</sup>

<sup>1</sup>*Microbiology, Utrecht University, Utrecht, Netherlands*

Fungi form colonies that consist of a network of hyphae. Macro-colonies with a diameter > 1 cm are formed on solid media, while micro-colonies with a diameter in the mm-scale are formed in liquid shaken cultures such as bioreactors. Research in our lab has revealed that micro- and macro-colonies are not a collection of hyphae with a synchronized activity. Fungal micro-colonies within a liquid culture are heterogeneous in gene expression and size. Heterogeneity in RNA composition can even be found between and within zones of macro- and micro-colonies. These findings imply that gene regulatory networks will not be correctly predicted by using whole cultures and colonies. This will be illustrated by regulatory networks of amylolytic genes and genes involved in asexual development. The finding of heterogeneity came to a surprise considering the fact that hyphae of higher fungi are compartmentalized with septa that contain large pores. These pores enable cytoplasmic streaming. It has now become clear that cytoplasmic streaming in aspergilli is reduced by dynamic plugging of septa. Modelling has shown that even open septa are a barrier for cytoplasmic mixing.

**The microtubule cytoskeleton in *Aspergillus nidulans***

R. Fischer<sup>1</sup>

<sup>1</sup>*Institute for Applied Biosciences Microbiology,  
Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany*

Polar growth in fungi requires intact microtubule and actin cytoskeletons. Both cytoskeletons consist of filamentous structures composed of alpha/beta tubulin dimers and actin monomers, respectively. The formation of both cytoskeletons is interdependent and relies on a class of so called cell-end marker proteins. The organization of the two cytoskeletons guarantees the directed travel of secretory vesicles. We found in *Aspergillus nidulans* that hyphal extension occurs in pulses at small areas at the hyphal tip rather than uniformly. Sites of secretion are only maintained for a short period before new sites are established.

*A. nidulans* harbors two genes encoding alpha tubulin and two genes encoding beta-tubulin. However, 2-D protein analyses revealed early on that tubulin can be post-translationally modified. Such modifications are a common phenomenon in eukaryotes, but their role is largely unknown. One modification is the C-terminal removal of tyrosin from alpha tubulin. The missing tyrosin can be re-added to alpha/beta tubulin dimers. Hence there is a cycle of detyrosination and tyrosination which determines the amount of modified alpha tubulin. Such modifications have not yet been described in fungi. We found that the kinesin 3 motor UncA binds preferentially to a subpopulation of microtubules in *A. nidulans* and also in *N. crassa*. We have evidence that the subpopulation consists of detyrosinated alpha tubulin and that the tail of UncA is required for the specificity. However, recent results suggest that the UncA tail harbours a microtubule-binding site and that the motor can interact with the motor domain with one microtubule and with the tail with a adjacent one. Thus UncA could be involved in bundling of microtubules.

**Establishment of the fungal mycelium**

**Signaling cascades associated with fungal cell-cell communication and trophic growth**

S. Seiler<sup>1</sup>

<sup>1</sup>*Biology II - Plant Physiology, Albert-Ludwigs-University Freiburg, Freiburg, Germany*

Intercellular communication is critical for the survival of unicellular microbes as well as for the development and function of multicellular tissues in higher eukaryotes. Cell-to-cell signaling is also required to develop the interconnected mycelial network characteristic of filamentous fungi and is a prerequisite for symbiotic and pathogenic host colonization achieved by molds. Somatic cell-cell communication and subsequent cell fusion is governed by the MAK-2 mitogen activated protein kinase (MAPK) cascade in the filamentous ascomycete model *Neurospora crassa*, yet the composition and mode of regulation of the MAK-2 pathway are currently unclear. In order to identify additional components involved in MAK-2 signaling we performed affinity purification experiments coupled to mass spectrometry with strains expressing functional GFP-fusion proteins of the MAPK cascade. This approach identified STE-50 as regulatory subunit of the yeast Ste11 homolog NRC-1 and HAM-5 as cell-communication-specific scaffold protein of the MAPK cascade. Moreover, we defined a network of proteins consisting of two Ste20-related kinases, the small GTPase RAS-2 and the adenylate cyclase capping protein CAP-1 that function upstream of the MAK-2 pathway and whose signals converge on the NRC-1/STE-50 MAP3K complex and the HAM-5 scaffold. Finally, our data imply the COT-1 NDR kinase network as effector module of the MAK-2 pathway to control the chemotrophic behavior of the two communicating cell tips. Taken together, these data have implications for our mechanistic understanding of MAPK pathways and their regulation during intercellular communication in eukaryotic microbes.

**Establishment of the fungal mycelium**

**Insights into the early regulation of conidiospore development in *Aspergillus nidulans***

U. Ugalde<sup>1</sup>, M. Iradi<sup>1</sup>

<sup>1</sup>*Applied Chemistry, Faculty of Chemistry, Donostia-San Sebastian, Spain*

Fungal hyphae are capable of undergoing different developmental programmes, thus enabling the mycelium to perform diverse biological functions simultaneously.

*Aspergillus nidulans* mycelia expand by means of vegetative hyphae at the colony periphery. At sub-peripheral regions, hyphae give rise to conidiophores bearing aerial mitospores (conidiospores) suitable for dispersal. At distal regions, hyphae support cleistothecium formation and eventually meiospores (ascospores), with long-term survival capabilities. The relative proportions of these cell-types can be further modulated to suit environmental conditions.

Three decades of molecular genetic research have unveiled the most important factors participating in the regulation of conidiophore development. Those already expressed in vegetative cells prior to the onset of development have been shown to participate in cell fate determination. Moreover, their characterisation has revealed that protein-protein interactions between these factors and their counterparts for cleistothecium formation, into protein complexes, are at the core of cell fate determination. Indeed, the alternative patterns of complex formation may well determine the alternative patterns of development.

In this presentation, we review the interaction patterns described for the velvet family of proteins VeA, VelB, VosA and VelC, the red light photosensor FphA, and the blue light photosensors LreA and LreB. We shall also incorporate interactions involving FluG and FlbA-E, developmental regulators specifically associated with conidiophore formation. An updated model of interactions leading to the determination of alternative developmental programmes will be presented.

#### **231 years after Lavoisier, in times of systems ecology – what tells us biological calorimetry?**

T. Maskow<sup>1</sup>, M.T. Weichler<sup>1</sup>, S. Paufler<sup>1</sup>

<sup>1</sup>*Department of Environmental Microbiology,  
Helmholtz Centre for Environmental Research-UFZ, Leipzig, Germany*

Heat is an unavoidable side-product of all life processes. Already in 1784 reported the father of quantitative chemistry – Antoine Laurent de Lavoisier – on the first measurement of the metabolic heat of a guinea pig and made first attempts to offer an interpretation. The main advantages of heat as an indicator for life processes are the reflection of any metabolic changes in real time and the tight correlation to metabolic fluxes and thermodynamic driving forces. Nowadays, even commercially available calorimetric instruments achieve detection limits low enough to measure the heat of 100 000 aerobically growing bacteria or of 100 myocardial cells. Heat can be monitored in reaction vessels ranging from a few nanoliters up to many cubic meters. In contrast to many traditional and emerging microbiological methods, heat flux measurements do not need labeling agents and reactants and also works with optically opaque solutions. It is further possible to assemble the thermal transducer in a protected way that reduces aging and thereby signal drifts.

All of these advantages make calorimetry an interesting tool for many applications in medicine and biotechnology. Unfortunately, metabolic heat signals are currently mainly used to monitor and control biological processes and their full information potential remains unexploited. However, new omics technologies offer a flood of information about complex biological and ecological systems. These detail information open the chance to be combined with calorimetric measurements and thermokinetic modelling to provide a holistic picture of the complex system under consideration. Various methods for quantitative data interpretations and their dependency on the applied calorimetric device and available additional biometric data will be presented and discussed. Also potential misinterpretations are considered.

#### **A novel biochemical trick of anaerobic microorganisms to deal with complicated thermodynamic situations**

R.K. Thauer<sup>1</sup>

<sup>1</sup>*Biochemistry, Max Planck Institute for Terrestrial Microbiology, Marburg, Germany*

Flavin-based electron-bifurcation is a recently discovered mechanism of coupling endergonic to exergonic redox reactions in the cytoplasm of anaerobic bacteria and archaea (1-7). The seven electron-bifurcating complexes characterized to date have in common that they catalyze the reduction of ferredoxin and of a second electron acceptor with NADH, NADPH, dihydrogen or formate as electron donors, the latter having a redox potential between that of ferredoxin and of the second electron acceptor. Via this mechanistic "trick" low potential electrons are generated that are used for energy conservation and biosyntheses in strict anaerobe such as Clostridia, acetogenic bacteria, methanogenic archaea and sulfate reducing bacteria.

### Thermodynamics in ecology and systems biology

#### **A thermodynamic theory of microbial growth and its perspectives for a better understanding of community dynamics**

T. Bouchez<sup>1</sup>, E. Desmond-Le Quémener<sup>1</sup>, H. Delattre<sup>1</sup>

<sup>1</sup>*Hydrosystems and bioprocesses research unit, Irstea, Antony, France*

The study of microbes, the simplest form of life, constitutes a fertile thinking ground for a deeper interlinking between physical and biological concepts. In 1922, Alfred Lotka suggested that the similarity between individuals was an invitation to imagine a "statistical mechanics of living beings"<sup>1</sup>. As an extension of these ideas, we proposed a thermodynamic theory of microbial growth by showing how systems constituted by microbes in contact with molecules could be likened to ensembles described by the laws of statistical physics. Based on thermodynamic balances established by different authors<sup>2</sup>, we defined the "activation energy" of a microbe and thus the probability for an elementary division act to be triggered. A growth equation could be proposed<sup>3</sup>, which links a flux (the growth of microbes) to a force (the free energy density in the environment). The equation allows adequate modeling of experimental growth data. More importantly, it also allows making new predictions in relation to the microbial isotopic fractionation phenomenon which can be viewed as a kinetic consequence of the differences in energy contents of isotopic isomers used for growth. We showed how recent experimental data actually support these original predictions. In the future, we plan to use our thermodynamic growth equation for modelling microbial community dynamics and studying the convergence of microbial ecosystems. Indeed our law offers a mathematical framework that may help understand the relevance of thermodynamic ecological goal functions such as dissipated power, exergy or entropy production.

**Mechanistic basis of equal plasmid spacing by the parABC system**

M. Howard<sup>1</sup>

<sup>1</sup>*Computational and Systems Biology, John Innes Centre, Norwich, United Kingdom*

Low copy number plasmids in bacteria require segregation for stable inheritance through cell division. This is often achieved by a *parABC* locus, comprising an ATPase ParA, DNA-binding protein ParB and a *parC* region, encoding ParB-binding sites. These minimal components space plasmids equally over the nucleoid, yet the underlying mechanism is not understood. Here we investigate a model where ParA-ATP can dynamically associate to the nucleoid and is hydrolyzed by plasmid-associated ParB, thereby creating nucleoid-bound, self-organizing ParA concentration gradients. We show mathematically that differences between competing ParA concentrations on either side of a plasmid can specify regular plasmid positioning. Such positioning can be achieved regardless of the exact mechanism of plasmid movement, including plasmid diffusion with ParA-mediated immobilization or directed plasmid motion induced by ParB/*parC*-stimulated ParA structure disassembly. However, we find experimentally that *parABC* from *Escherichia coli* plasmid pB171 increases plasmid mobility, inconsistent with diffusion/immobilization. Instead our observations favor directed plasmid motion. Our model predicts less oscillatory ParA dynamics than previously believed, a prediction we verify experimentally. We also show that ParA localization and plasmid positioning depend on the underlying nucleoid morphology, indicating that the chromosomal architecture constrains ParA structure formation. Our directed motion model unifies previously contradictory models for plasmid segregation and provides a robust mechanistic basis for self-organized plasmid spacing that may be widely applicable.

**The role of gene expression noise in the evolution of gene regulation**

E. van Nimwegen<sup>1</sup>, L. Wolf<sup>1</sup>, O. Silander<sup>1</sup>

<sup>1</sup>Biozentrum, University of Basel, Basel, Switzerland

Although it is often tacitly assumed that gene regulatory interactions are finely tuned, it is unclear how accurate gene regulation could evolve de novo from a state without regulation. Moreover, gene expression noise would seem to impede the evolution of accurate gene regulation, and the fact that expression noise varies greatly across genes suggests natural selection has affected noise levels. To infer how selection has tuned noise levels of *E. coli* promoters, we designed a novel synthetic biology approach in which we evolved a large library of synthetic promoters de novo. We show that, surprisingly, promoters exhibit low noise by default, and rather than having acted to lower noise levels, selection must have acted to raise noise levels of a substantial fraction of *E. coli* promoters. In addition, promoters with elevated noise levels are precisely those that are highly transcriptionally regulated.

To explain the general association between expression noise and gene regulation, it has been argued that elevated expression noise may either be directly selected as a 'bet hedging strategy', or that it may be a detrimental but unavoidable side-effect of regulation. We here present a general theory for the interplay of expression noise and gene regulation which shows that this is a false dichotomy: expression noise can be both a necessary consequence of regulation and a beneficial bet hedging strategy at the same time. Moreover, this theory elucidates how regulation can evolve incrementally starting from a state without regulation. Noise propagation from regulators to targets acts as a rudimentary form of regulation, and noisy expression is not a nuisance but rather a stepping stone toward the emergence of accurate gene regulation.

**Computational modelling**

**Stochasticity and homeostasis in cellular growth**

S. Tans<sup>1</sup>

<sup>1</sup>*Systems Biophysics, AMOLF institute, Amsterdam, Netherlands*

Elucidating the role of molecular stochasticity in cellular growth is important to understanding phenotypic heterogeneity and the stability of cellular proliferation. We used time-lapse microscopy to measure fluctuations in the instantaneous growth rate of single cells of *Escherichia coli* and in the expression of metabolic enzymes. We show that expression fluctuations of catabolically active enzymes can propagate and cause growth fluctuations. Conversely, growth fluctuations propagate back to perturb expression. Homeostasis is promoted by a noise-cancelling mechanism that exploits fluctuations in the dilution of proteins by cell-volume expansion. Thus, molecular noise is propagated not only by regulatory proteins but also by metabolic reactions. The results suggest that cellular metabolism is inherently stochastic, and a generic source of phenotypic heterogeneity.

**How bacteria can maximise their growth rate under stress conditions**

F. Bruggeman<sup>1</sup>

<sup>1</sup>*Systems Bioinformatics, VU University, Amsterdam, Netherlands*

Large population-sizes and the exponential increase in the abundance of fit genotypes makes growth-rate selection a powerful force that shapes bacterial survival strategies. Bacteria have to therefore carefully balance growth and stress tasks to prevent being outcompeted during nutrient-excess and stress conditions. In this talk, I will discuss several principles of bacterial-fitness optimisation, starting from basic relations of biochemistry, steady-state metabolism and growth-rate maximisation. The resulting theory explains how bacteria should balance growth and stress tasks to optimise fitness. Using this theory, several experimental findings can be explained. Those findings include how *E. coli* regulates its ribosome synthesis via ppGpp, the fitness costs of protein overexpression and the shape of fitness landscapes.

**Bio-synthetic routes based on new enzymatic reactions**

B. Hauer<sup>1</sup>

<sup>1</sup>*Institute of Technical Biochemistry, Universitaet Stuttgart, Stuttgart, Germany*

Traditionally, new enzyme activities have been discovered by screening microorganisms and mutant libraries. In recent years, these strategies were successfully expanded by a mechanism-based approach. Hereby, the catalytic machinery of known enzymes is harnessed to perform not only the same type of chemistry with different substrates but also to catalyze completely new non-physiological reactions. To identify initial activity and to address the catalytic flexibility, small and functionally rich enzyme libraries have been used. This presentation will highlight hidden as well as uninvestigated enzymatic activities and will illustrate strategies to unmask them. For example, we have recently harnessed the unique protonation machinery of squalene hopene cyclases to generate enzymes for non-natural chiral Brønsted acid catalysis.

The identification of novel enzymatic transformations enables complete new biosynthetic routes to interesting molecules. Examples like menthol, sebacic acid or heterocyclic compounds will be given which also explains how these new reactions can be applied in a retrosynthetic approach.

<sup>2</sup>*Institute of Molecular Plant Sciences, University of Edinburgh, Edinburgh, United Kingdom*

<sup>3</sup>*Biochemistry, University of Turku, Turku, Finland*

**Microbial biosynthesis and separation of alkanes and alcohols**

Economically sustainable conversion of solar energy and CO<sub>2</sub> into low value chemical energy (e.g. fuel) using biotechnology is a challenge. Several benefits can be imagined if the chemical product can be immediately separated from the (1) organisms that synthesized the product and (2) biotechnological process. These include enhanced product tolerance, reduced feedback inhibition, and enhanced pathway thermodynamics. In addition, by continuously removing the product, a continuous biotechnological process is possible. This allows the biological organism to act as a catalyst rather than as a substrate for further transformation. Several strategies for immediate product-process separation are possible: (a) a gaseous product spontaneously leaves the liquid phase, (b) excretion and engineered separation of a water-soluble liquid, (c) excretion and spontaneous separation of a hydrophobic liquid. In all above cases, it is necessary for the product to transfer through the cell envelope of the biocatalyst. Towards the objective of producing a useful fuel that can be easily separated, we have constructed several synthetic pathways for alkane and alcohol biosynthesis. The challenges and insight gained from this metabolic pathway and transporter engineering work will be summarised.

**Antibiotic resistance: human and veterinary medicine**

**Parallel but distinct evolution of *Pseudomonas aeruginosa* and *Acinetobacter baumannii* toward pan-drug resistance**

P. Plésiat<sup>1</sup>, K. Jeannot<sup>1</sup>, D. Fournier<sup>1</sup>

<sup>1</sup>National Reference Center for Antibiotic Resistance, Jean Minjoz hospital, Besancon, France

*Pseudomonas aeruginosa* and *Acinetobacter baumannii* have emerged as major nosocomial pathogens in the second half of the 20<sup>th</sup> century, as unexpected consequence of medical progress. These strictly aerobic bacilli share a high metabolic versatility and the ability to thrive in hostile environments. In addition to producing a complex array of virulence factors enabling them to infect fragile patients, both pathogens show a remarkable capacity to become resistant to all the antibiotics available. However, despite these apparent similarities, *P. aeruginosa* and *A. baumannii* differ in the mechanisms leading to such a high degree of resistance. Total recalcitrance of *P. aeruginosa* to  $\beta$ -lactams, the major class of antibiotics used in therapeutics, mostly relies on mutation-driven mechanisms (overproduction of intrinsic  $\beta$ -lactamase AmpC, porin OprD deficiency, activation of efflux systems) operating synergistically with a variety of extended-spectrum  $\beta$ -lactamases collected from environmental reservoirs via horizontal gene transfers. The parallel evolution of *A. baumannii* to pan- $\beta$ -lactam resistance involves IS-dependent up-regulation of natural  $\beta$ -lactamase ADC combined with conjugational acquisition of a limited number of OXA-type  $\beta$ -lactamases from closely-related species. Accumulating evidence suggests that the two microorganisms exploit distinct pools of resistance genes (resistomes) to reinforce their own resistance mechanisms, probably as a result of distinct ecological niches.

*Institute for Veterinary Medical Research Centre for Agricultural Research Hungarian  
Academy of Sciences (H.A.S), Budapest, Hungary*

The increasing challenge due to antimicrobial resistance of pathogenic bacteria in human-, and veterinary medicine prompted the general fear that several classes of antimicrobials are becoming more or less useless due to their prophylactic and/or therapeutic use for animals. In light of new knowledge on genomic flexibility and on clonal spreading of pathogens and/or commensal bacteria we aim to re-visit potential links of antimicrobial resistance between animals and man.

Data about possible ways of evolution of resistances against the most critical antimicrobials (third generation cephalosporins, fluoroquinolones and aminoglycosides) show that foodborne enteric pathogens like *Salmonella* and *Campylobacter* seem to be trafficking frequently from animals to man, with the occasional opportunity to transfer critical resistance determinants. In contrast to enteric pathogens, the dominant clones of non-enteritis causing antibiotic resistant bacteria - methicillin-resistant *Staphylococcus aureus* (MRSA), vancomycin-resistant *Enterococcus faecium*, multiresistant *Pseudomonas aeruginosa* - usually differ substantially in the human healthcare setting from those occurring in animals.

Adaption of distinct clones of bacteria to various species of animals or to humans may have contributed to the observed clonal diversity. The use of fluoroquinolone type antibiotics could also emerge as an enhancer of major international clones of MRSA and of some additional multiresistant pathogens.

Thus, evolution and spread of resistant enteric isolates is frequently driven by the development of some major clones originating and spreading from/within human clinical settings, while the resistant clones of animal/food origin seem to be more diverse with a partial human overlap. Therefore, the differences in spreading antimicrobial resistance within and between differing epidemiological compartments of animals and humans should be considered more analytically.

**Antibiotic resistance: human and veterinary medicine**

**A NOVEL D-ALANINE-D-ALANINE LIGASE GENE FROM HUMAN ORAL METAGENOMIC DNA CONFERS HIGH-LEVEL RESISTANCE TO D-CYCLOSERINE**

M.A. Rahman<sup>1</sup>, P. Mullany<sup>1</sup>, A.P. Roberts<sup>1</sup>

<sup>1</sup>Microbial Diseases, UCL Eastman Dental Institute, London, United Kingdom

**Background**

The human oral cavity is a reservoir for antibiotic resistance genes. While investigating integrons (a natural gene capture and expression system) and their associated gene cassettes from the human oral cavity, we identified two variants of D-alanine-D-alanine ligase (*ddl*) predicted to encode novel variants of the protein. The Ddl enzymes catalyse the synthesis of D-Ala-D-Ala dipeptide during the early stage of peptidoglycan biosynthesis. D-Cycloserine (DCS) is a Ddl inhibitor and is used as a second-line antibiotic to treat multidrug-resistant and extensively drug-resistant *Mycobacterium tuberculosis*. Overexpression of *ddl* genes from either *Mycobacterium smegmatis* or *M. tuberculosis* has been shown to confer resistance to DCS in *M. smegmatis*.

**Objectives**

The aim of this study is to test the hypothesis that *ddl*, identified on integron gene cassettes from a human oral metagenome may confer resistance to DCS.

**Methods**

Minimum Inhibitory Concentration (MIC) of DCS in *Escherichia coli* and *Bacillus subtilis* overexpressing the *ddl* variants was determined by agar dilution method according to the guidelines of Clinical and Laboratory Standards Institute (CLSI).

**Conclusions**

We observed that one variant of *ddl* confers resistance to DCS in *E. coli* and *B. subtilis* with an MIC of 128 µg/ml and 256 µg/ml, respectively. The other variant confers resistance with an MIC of 64 µg/ml and 256 µg/ml, respectively.

These results represent the first time that *ddl* has been found on an integron cassette suggesting that it is important in host adaptation to stress (e.g. cell wall targeting antibiotics). The mechanism by which Ddl confers DCS resistance is currently being characterised.

## **GUT RESISTOME DEVELOPMENT IN NEONATES MONITORED IN A COHORT STUDY**

C.J.H. von Wintersdorff<sup>1</sup>, J. Penders<sup>1</sup>, P.H.M. Savelkoul<sup>1</sup>, R.R.R. Nijssen<sup>1</sup>,  
E. Hamelmann<sup>2</sup>, S. Lau<sup>2</sup>, K. Gerhold<sup>2</sup>, P.F.G. Wolfs<sup>1</sup>

<sup>1</sup>Medical Microbiology, Maastricht University Medical Center, Maastricht, Netherlands

<sup>2</sup>University Children's Hospital St Josef, Ruhr-Universität Bochum, Bochum, Germany

### **Background**

The antibiotic resistance of pathogenic bacteria has been studied extensively. However, recently the collection of antibiotic resistance genes (ARGs) in the gut microbiota (resistome) has been acknowledged as an important reservoir of ARGs. The establishment of the human gut resistome is ideally studied in the pediatric microbiota.

### **Objectives**

Our objective was to investigate the presence of various ARGs in the microbiota of newborns in the weeks following birth.

### **Methods**

Within a prospective cohort among neonates born between 2000-2007, fecal samples collected at the ages of 5, 13 and 31 weeks postpartum were analyzed from a random selection of 120 infants. Inclusion criteria included healthy newborns at term, birth weight of  $\geq 2500$ g, and informed consent. Fecal samples were subjected to targeted metagenomics by qPCR for the detection of ARGs *cfxA*, *tetM*, *tetQ*, *aac-aph*, *ermB* and *qnrS*. The microbial composition in all samples was determined in a previous study. Prevalence was compared by using a McNemar's test for paired samples. Risk factors were analyzed by using logistic regression.

### **Conclusions**

Results show that acquisition of ARGs in the gut microbiota occurs already within the first weeks after birth and that the prevalence of these genes in the microbiota of newborns is highly variable over the course of a few weeks (Figure). Mode of delivery as well as duration of breastfeeding brought about significant changes in the prevalence of ARG. Relating ARG prevalence to microbiome analysis indicated that

changes in microbial composition are partly responsible for shifts in the resistome.

**MOLECULAR CHARACTERISTICS OF EXTENDED-SPECTRUM  
CEPHALOSPORIN-RESISTANT ENTEROBACTERIACEAE FROM HUMANS IN  
THE COMMUNITY DIFFER FROM THOSE IN BROILERS**

A.H.A.M. van Hoek<sup>1</sup>, L. Schouls<sup>1</sup>, M.G. van Santen<sup>1</sup>, A. Florijn<sup>1</sup>, S.C. de Greeff<sup>1</sup>,  
E. van Duijkeren<sup>1</sup>

<sup>1</sup>Centre for Infectious Disease Control,

National Institute for Public Health and the Environment, Bilthoven, Netherlands

**Background**

ESBL/AmpC-producing Enterobacteriaceae have frequently been reported in broilers and therefore they have been considered as a reservoir for ESBL/AmpC-encoding resistance genes with the potential to transmit to humans.

**Objectives**

The objective was to investigate the molecular characteristics of extended-spectrum cephalosporin (ESC)-resistant Enterobacteriaceae collected during a cross-sectional study examining the prevalence of faecal carriage of extended-spectrum  $\beta$ -lactamase (ESBL)-producing Enterobacteriaceae in a population sample of humans living in areas with high or low broiler density.

**Methods**

ESC-resistant Enterobacteriaceae were identified by combination disc-diffusion test. The presence and composition of ESBL/AmpC/carbapenemase encoding genes were assessed by PCR and sequencing. For *Escherichia coli*, phylogenetic groups and MLST were determined.

**Conclusions**

175 ESC-resistant Enterobacteriaceae were cultured from 165 of 1,033 sampled persons, yielding a prevalence of 15.9 %. No carbapenemase genes were identified. Most isolates were *Escherichia coli* followed by *Citrobacter freundii* and *Enterobacter cloacae*. The predominant ESBL genes were *bla*<sub>CTX-M-1</sub>, *bla*<sub>CTX-M-15</sub> and *bla*<sub>CTX-M-14</sub>, but other allelic variants were also identified as well *bla*<sub>SHV-12</sub> and *bla*<sub>TEM-52</sub>. The most common AmpC genes were *bla*<sub>CMY-2</sub> and *bla*<sub>CMY-48-like</sub>. A large variety of *E. coli* genotypes was found, ST131 and ST10 being most common. ESBL/AmpC genes in Enterobacteriaceae obtained from the community resembled those found in isolates from patients in Dutch hospitals, indicating that healthy humans act as a reservoir for transmission of these determinants to vulnerable people. In contrast, the molecular characteristics of *E. coli* isolates differed from those of broilers suggesting that

broilers are not an important source of ESBL/AmpC genes for humans living in the community.

**TRACKING IS26 MEDIATED IN VIVO GENE-SHUFFLING EVENTS ORIGINATING FROM A COMPLEX MULTI-DRUG RESISTANCE LOCUS**

P. Roy Chowdhury<sup>1,2</sup>, J. McKinnon<sup>1</sup>, I.G. Charles<sup>1</sup>, S.P. Djordjevic<sup>1</sup>

<sup>1</sup>The iThree institute Faculty of Science, University of Technology Sydney, Sydney, Australia

<sup>2</sup>NSW Department of Primary Industries, Elizabeth Macarthur Agricultural Institute, Camden, NSW, Australia

**Background**

The insertion element IS26 is known to play a crucial role in the rapid evolution of complex drug resistance loci (CRL) of Gram-negative pathogens by shuffling and/or disseminating clustered drug resistance genes. Until recently, the unique molecular mechanisms involved in the mobilization of DNA fragments flanked by IS26 elements were unknown. A model, describing the generation of diverse types of IS26-derived mobile units has now been established using simple artificially constructed resistance units to support the proposed molecular mechanisms. To the best of knowledge, the impact of IS26-mediated gene reshuffling events on naturally occurring CRLs containing multiple copies of IS26 has never been demonstrated.

**Objectives**

To characterize IS26-mediated laterally mobile resistance subunits that have the potential to originate from a specific complex resistance locus.

**Methods**

Combinations of Illumina and Sanger DNA sequencing, gene cloning and qPCR analytical techniques were used.

**Conclusions**

We identified a 27kb resistance locus (containing seven copies of IS26 and genes conferring resistance to five different classes of clinically relevant antibiotics) from the genome sequence of an *Escherichia coli* isolate belonging to sequence type 405, a major emerging uropathogenic *E. coli* clone implicated in the global dissemination of the *bla*<sub>CTX-M15</sub> gene. We have irrefutably tracked formation of five, of 16 possible, laterally mobile units encoding resistance to different combinations of clinically important antibiotics from the 27kb CRL. Our assays on the CRL documents, for the first time, IS26-mediated horizontal gene mobilisation events *in-vivo* and experimentally confirm the imperative role played by IS26 in rapid evolution of CRL.

**Microbial transformations of metals and metalloids**

**Ecology and mechanisms of microbial Fe(II) oxidation**

A. Kappler<sup>1</sup>

<sup>1</sup>*University of Tübingen, Geomicrobiology, Tübingen, Germany*

The two most important redox states of iron in the environment are Fe(II) [ferrous iron] and Fe(III) [ferric iron]. Dissolved Fe(II) and relatively soluble Fe(II) minerals are abundant in many environments including pH-neutral soils, sediments and iron seeps. Oxidation of dissolved and solid-phase ferrous iron [Fe(II)] at neutral pH can be catalyzed by microaerophilic, nitrate-reducing and even phototrophic microorganisms and leads to the precipitation of poorly soluble Fe(III) minerals. These minerals influence the environmental fate of many nutrients and contaminants and the precipitation of Fe(III) minerals by these three microbial processes has been shown to occur in many modern environments and has been suggested to have been present already on early Earth.

This presentation will summarize the current knowledge and show results regarding mechanisms, physiology, and ecology of microbial Fe(II) oxidation. Special focus will be on microaerophilic Fe(II)-oxidizing bacteria that thrive in gradients of ferrous iron and oxygen and on phototrophic and nitrate-reducing Fe(II)-oxidizing bacteria in freshwater and marine sediments. I will present data on the isolation and quantification of microaerophilic, nitrate-reducing and phototrophic Fe(II)-oxidizers from different habitats as well as results regarding the quantification of their activities under different environmental conditions.

## **Microbial transformations of metals and metalloids**

### **Microbial oxidation of metal sulfur minerals**

N. Balci<sup>1</sup>

<sup>1</sup>*Department of Geology and Geological Engineering, Istanbul Technical University, Istanbul, Turkey*

### **MICROBIAL OXIDATION OF METAL SULFUR MINERALS**

Microorganisms can significantly impact oxidation rate of sulfur minerals such as pyrite, sphalerite, galena and arsenopyrite and thus regulate sulfur and metals cycles in various environments. A wide range of acidophilic bacteria and archaea are capable of catalyzing sulfur oxidation near the Earth's surface resulting in production of highly acidic, sulfate-rich solutions known as acid drainage which represents extreme geochemical conditions. Recent molecular ecology studies revealed that extreme geochemical conditions such as acid drainage sites that were previously thought lack of life due to limited nutrients and extreme conditions have diverse microbial populations. These DNA based findings open new directions for research dealing with sulfur oxidation by emphasizing interactions between microbe and sulfur minerals. .

Elucidating the role of microorganism on dissolution of metal sulfide minerals is the key to understand environmental consequences of metal sulfur oxidation and developing of proper remediation techniques. Dissolution and oxidation of metal sulfur minerals usually generates different sulfur species with a wide range of valence states from sulfide (2-) to sulfate (+6). One way to understand metal sulfur oxidation pathway is to use O and S isotopes of reactants and products that are first witness of dissolution reactions. Biotic and abiotic metal sulfide oxidation experiments (pyrite, sphalerite, galena, arsenopyrite and S<sup>0</sup>) was carried out with different *Acidophilic spp.* species under various environmental conditions. Modern analysis techniques in addition to  $\delta^{18}\text{O}$  and  $\delta^{34}\text{S}$  measurements of sulfur species were used to reveal oxidation mechanism (biotic vs. abiotic) of each sulfur mineral. Results will be discussed in detail to step towards understanding of microbial role on the dissolution kinetics of sulfur minerals.

**Key Words:** Enzyme, metal sulfur, isotope, DNA, dissolution

#### **BIOLEACHING OF STRATEGIC ELEMENTS FROM PRIMARY AND SECONDARY RESOURCES**

M. Schlömann<sup>1</sup>, N. Gelhaar<sup>1</sup>, C. Klink<sup>1</sup>, S. Schopf<sup>1</sup>, S. Eisen<sup>1</sup>, J. Heim<sup>2</sup>, B. Daus<sup>3</sup>

<sup>1</sup>*Interdisciplinary Ecological Center, TU Bergakademie Freiberg, Freiberg, Germany*

<sup>2</sup>*Geobiotechnology, Helmholtz Institute Freiberg for Resource Technology, Freiberg, Germany*

<sup>3</sup>*Dept. for Analytics,*

*Helmholtz Center for Environmental Research UFZurce Technology, Leipzig, Germany*

#### **Background**

The prices of some economically strategic elements, e. g. indium, germanium, rhenium, vanadium, and antimony, due to their use for high-tech products have increased to an extent which raises the question, whether these elements can be obtained from complex ores or secondary resources also in Germany.

#### **Objectives**

The aim of the studies was to identify bacterial cultures and conditions under which metals mentioned above by microbial activity can be brought into solution. Indium was to be obtained from sphalerite (ZnS) of the ore mountain region around Freiberg, the other strategic metals from "Theisen sludge" which resulted from fine-grained flue dust of former copper smelters and which had been deposited in the Mansfeld area, Germany.

#### **Methods**

For indium from sphalerite molecular analyses of the microbial community of acidic waters in the mine "Reiche Zeche" were performed to identify suitable leaching communities. To obtain other elements from "Theisen sludge" appropriate strains were enriched. All leaching experiments were initially performed in shake flasks in several media by pure or mixed cultures, and compared to abiotic controls. Then bioreactor studies were performed. Redox potential, pH, and metal concentrations were determined.

#### **Conclusions**

Between 80 and 100% of the zinc were leached from sphalerite in 9K and DSM 882 medium by mixed cultures from various sources including "Reiche Zeche" as well as by *Acidithiobacillus ferrooxidans* DSM14882<sup>T</sup>. Due to a co-precipitation of indium with jarosite, an increase in the solids loading resulted in a lower increase of indium as compared to zinc in solution. The other elements mentioned could successfully be leached from "Theisen sludge".

**BOIFILM CONTRIBUTIONS TO MARINE CORROSION OF 70/30 CUNI ALLOYS**

Z. Makama<sup>1</sup>, I.B. Beech<sup>1</sup>, J. Sunner<sup>1</sup>, S.A. Campbell<sup>2</sup>, J. Galsworthy<sup>3</sup>, R. Oakley<sup>3</sup>,  
M. Kowalski<sup>1</sup>, L. Cieslak<sup>1</sup>

<sup>1</sup>*Microbiology and Plant Biology, University of Oklahoma, Norman, USA*

<sup>2</sup>*Pharmacy and Biomedical Sciences, University of Portsmouth, Portsmouth,  
United Kingdom*

<sup>3</sup>*Cody Technology Park, QinetiQ, Farnborough, United Kingdom*

**Background**

In marine environments, the activity of microorganisms which form biofilms on metallic materials such as Cu, Fe, Al, and their alloys can result in severe deterioration of these materials, a phenomenon known as microbiologically-influenced corrosion (MIC). It is accepted that biofilms comprising diverse microbial populations are more aggressive towards metals than monoculture biofilms. It has also been proposed that corrosion rates observed in the presence of microbial consortia are related to cooperative metabolic activities of biofilm population, as well as the chemical properties of the colonised surface. As a result of their corrosion resistance, thermal conductivity and reported anti-fouling properties, CuNi alloys find many applications in marine environments and are used extensively in heat-exchangers, pipelines and cladding materials. The stability of these alloys in chloride-containing media has been attributed to the presence of a duplex oxide layer on the alloy surface. However, it has been demonstrated the protective oxide structure on CuNi alloys does not prevent, and merely delay the onset of macrofouling and that these alloys are susceptible to MIC.

**Objectives**

Advanced electron microscopy, surface science and molecular ecology techniques, such as pyrosequencing have been used to characterise the enrichments and resulting biofilms.

**Methods**

Continuous flowing bioreactors operating at 10 C and 24 C have been employed to expose CuNi coupons with different surface pre-treatments to aerobic and anoxic microbial enrichments obtained from marine biofilm samples recovered from corroding and non-corroding systems.

**Conclusions**

The study revealed that there was a correlation between the microbial community structure and the extent of localised corrosion attack.

### Microbial transformations of metals and metalloids

#### CAN WE EXPLOIT BACTERIA AND FUNGI TO PRESERVE ARCHAEOLOGICAL IRON OBJECTS?

L. Comensoli<sup>1</sup>, J. Maillard<sup>2</sup>, P. Junier<sup>1</sup>, E. Joseph<sup>1,3</sup>

<sup>1</sup>*Institute of Biology - Laboratory of Microbiology, University of Neuchâtel, Neuchâtel, Switzerland*

<sup>2</sup>*Laboratory for Environmental Biotechnology, Swiss Federal Institute of Technology, Lausanne, Switzerland*

<sup>3</sup>*Haute Ecole Arc Conservation-Restauration, Neuchâtel, Switzerland*

#### Background

Without any conservation-restauration intervention, archaeological iron objects are affected by **dramatic corrosion** that leads to an **irreversible deterioration**. The main issue with this metallic substrate is the chlorine content within the corrosion layers that, reacting with H<sub>2</sub>O and O<sub>2</sub>, causes flacks, cracks and loss of shape of the objects after excavation. Conservation-restauration methods nowadays available are expensive, time consuming and often employ toxic substances.

#### Objectives

Therefore, the MAIA (Microbe for Archaeological Iron Artworks) project aims to develop alternative **conservation-restauration methods for iron artefacts that will be based on the use of microorganisms**.

#### Methods

For this purpose, two metabolic activities of specific microorganisms were studied. First we tested **iron reduction/accumulation by anaerobic bacteria and fungi**, leading to the formation of stable molecules of low molar volume; and second, the capacity of **translocating and/or accumulating chlorine** by fungi.

In order to identify some microorganisms with the desired iron metabolism, two anaerobic bacterial strains of *Desulfitobacterium hafniensis* (LBE and TCE1) and several fungal strains were studied. Different iron sources were tested either as soluble (iron citrate) or solid phases (powdered iron compounds from real objects). Spectrophotometric analyses were carried out to ascertain iron reduction and bacterial growth was followed by qPCR. Analyses by SEM allowed studying the iron and chlorine absorption by fungi, and finally, *Fourier Transform Infrared* (FTIR) and *Raman Spectroscopies* were used to identify the bio-minerals produced.

#### Conclusions

The results show that microbes have the potential to stabilize iron objects by both reduction into more stable minerals and by removing chloride from the object.

#### **USE OF ENDOSPORE-FORMING FIRMICUTES FOR THE BIOREMEDIATION OF TRACE-METALS**

M. Bueche<sup>1</sup>, N. Sieber<sup>1</sup>, P. Junier<sup>1</sup>

<sup>1</sup>*Microbiology, University of Neuchâtel, Neuchâtel, Switzerland*

#### **Background**

In urban environments, run-off water constitutes a sink for metals as it collects dust particles produced by human activities. In the case of the city of Lausanne (Switzerland), run-off and wastewater is not yet entirely separated. As a consequence, the wastewater treatment plant of Lausanne rejects metal contaminated effluent water into the lake of Geneva, leading to an enrichment of lake sediment by metals like copper, cadmium and zinc. In this environment a link between metal contamination and the relative abundance of endospore-forming Firmicutes was clearly observed. Further investigations tend to show that bacterial exudates, massively produced by these bacteria, play an important role in the chelation and immobilization of metals.

#### **Objectives**

The objective of this study is to achieve a better understanding of this relation between endospore-forming Firmicutes and metals in aquatic environments. Is it particular to environments under the influence of wastewater treatment plant rejections or could it be generalized to other polluted environments? The chelation mechanism is also of particular interest.

#### **Methods**

To achieve this, sediment cores from different location (two different lakes) were analyzed, looking for bacterial communities composition (454-pyrosequencing), but also physico-chemical characteristics, like metals content (ICP-MS measurement). Cultivation experiments in media amended with different concentrations of metals was also initiated, first for evaluating the chelation potential of the different strains tested (ICP-OES), second for isolating and investigating the chelation substances that were produced (SEM and FTIR).

#### **Conclusions**

A better understanding of the metal immobilization processes by bacterial biomass could lead to promising bioremediation technologies.

**FEMS-0906**

**Archaea and life in extreme environments**

**The archaellum: How archaea swim**

S.V. Albers<sup>1</sup>

<sup>1</sup>*Molecular Biology of Archaea, University of Freiburg, Freiburg, Germany*

Motility is an important feature for all life forms. Whereas bacteria use the well studied flagellum for swimming motility, archaea employ the archaellum, which is a rotating type IV pilus like structure. The crenarchaeal archaellum is only composed of seven subunits that are essential for the assembly and rotation of the archaellum. Next to the structural filament protein FlaB, the *S. acidocaldarius* archaellum operon encodes for the monotopic membrane proteins FlaX, FlaF and FlaG, whereas the motor complex is formed by the nucleotide binding protein FlaH, the ATPase FlaI and the polytopic membrane protein FlaJ.

Our current functional and structural analysis of the different archaellum components will be discussed as well as their role in assembly and rotation of the archaellum.

<sup>3</sup>Environment, National Research Council of Canada, Montreal, Canada

<sup>4</sup>NASA AMES, NASA, Ames, USA

<sup>5</sup>Earth & Planetary Sciences, McGill University, Montreal, Canada

This presentation will describe recent highlights of our research examining polar microbial biodiversity and microbial ecology in extreme polar cryoenvironments with a focus on the Archaeal components. In general, we have detected archaeal sequences (haloarchaea, methanogens, *Crenarchaeota*, *Thaumarchaeota*) from 16S surveys and metagenome sequencing projects in most of the habitats tested including Arctic and Antarctic permafrost soils, gypsum and sandstone cryptoendoliths, and saline and hypersaline cold perennial springs in the high Arctic of Canada, albeit at relatively less proportions (10 fold or greater) than Bacteria sequences. The Lost Hammer (LH) spring in the Canadian high Arctic perennially discharges subzero (-5°C) hypersaline (~24% salt) brines through thick layers of permafrost (> 500 m), and so far accounts for the only described terrestrial methane seep in frozen settings on Earth and serves as an analogue for possible Martian liquid water habitats. In the LH source sediments, archaeal phylotypes related to signatures from hypersaline deep-sea methane-seep sediments and were dominated by the anaerobic methane group 1a (ANME-1a) clade of anaerobic methane oxidizing archaea while spring channel sediments was dominated by phylotypes most closely related to ammonia-oxidizing *Thaumarchaeota*. Viral morphologies (fusiform, spherical) characteristic of archaeal viruses are present in the cold saline springs. Haloarchaea and methanogens are readily found in most permafrost soils and their role in CH<sub>4</sub> fluxes from melting Arctic permafrost environments will be presented. Overall, the roles and activities of *Archaea* in cryoenvironments, especially under ambient subzero conditions, remains very poorly elucidated and is significantly hampered by the lack of culturable archaeal representatives capable of subzero growth.

**FEMS-1447**

**Archaea and life in extreme environments**

**MOLECULAR MECHANISMS OF ACTION BY A TETR-FAMILY TRANSCRIPTION FACTOR IN SULFOLOBUS ACIDOCALDARIUS**

L. Lemmens<sup>1</sup>, E. Peeters<sup>1</sup>, D. Sybers<sup>1</sup>, A. Lindas<sup>2</sup>, K. Wang<sup>2</sup>

<sup>1</sup>Bio-engineering Sciences, Vrije Universiteit Brussel, Brussels, Belgium

<sup>2</sup>Molecular Biosciences, The Wenner-Gren Institute Stockholm University, Stockholm, Sweden

**Background**

Archaea, however also found in mainstream habitats, are characterized by several extremophilic species. Extremophilic microorganisms have more robust proteins and unique metabolic strategies to survive extreme conditions. *Sulfolobus acidocaldarius*, an aerobic thermoacidophilic crenarchaeon, is a promising host for biotechnological processes.

**Objectives**

Getting insight in the mode of action of transcriptional mechanisms could lead to a better understanding of archaeal physiology and to an extended transcriptional toolbox for genetic engineering of *Sulfolobus*. Gene regulation in response to environmental conditions is crucial for the fitness and survival.

This project focuses on the characterization of a TetR-like transcription factor, SaFadR.

**Methods**

A variety of biochemical techniques and *in vivo* experiments has been implemented to study DNA-binding behaviour and physiological role.

**Conclusions**

By analysing the interactions of the SaFadR protein with genomic regions, SaFadR binds *in vivo* ten genomic regions, with the highest affinity to its own promoter region and the one of a juxtaposed, divergently transcribed operon. Other ChIP-seq binding peaks were observed for an operon encoding enzymes involved in the  $\beta$ -oxidation pathway. This binding is confirmed *in vitro* by performing EMSA. Addition of a fatty acyl-CoA reduces the *in vitro* binding.

Using a SaFadR knockout strain, the relative expression levels of SaFadR and the other possible target genes were compared with an isogenic wild type by qRT-PCR.

Based on these results we can conclude that the SaFadR protein is a fatty acid responsive transcription factor that represses genes involved in fatty acid and lipid metabolism in a fatty acyl-CoA dependent manner.

**FEMS-1783**

**Archaea and life in extreme environments**

**POTENTIAL PH ADAPTATION MECHANISMS IN THE NOVEL ACIDOPHILIC IRON OXIDISER “FERROVUM” SP. JA12 INVOLVE A UREASE**

S.R. Ullrich<sup>1</sup>, A. Poehlein<sup>2</sup>, R. Daniel<sup>2</sup>, J.S. Tischler<sup>1</sup>, M. Schlömann<sup>1</sup>, M. Mühling<sup>1</sup>

<sup>1</sup>TU Bergakademie Freiberg, Institut für Biowissenschaften, Freiberg, Germany

<sup>2</sup>Georg-August-Universität Göttingen,

Genomic and Applied Microbiology & Göttingen Genomics Laboratory, Göttingen, Germany

**Background**

Members of the novel proposed order “*Ferrovales*” are the first acidophilic iron oxidising bacteria within the *Betaproteobacteria*.

**Objectives**

Since neutrophiles and acidophiles seem to use different strategies to maintain pH homeostasis and to cope with acid stress we were interested in the strategies of the novel acidophile “*Ferrovum*” sp. JA12.

**Methods**

Therefore we sequenced and assembled the complete genome sequence of “*Ferrovum*” sp. JA12, derived from the acid mine drainage of a lignite mining site.

**Conclusions**

The genome analysis revealed the gene repertoire for both the typical strategies of acidophiles and of neutrophiles. Like other acidophiles “*Ferrovum*” sp. JA12 may be able to create a reverse membrane potential by the increased uptake of potassium ions facilitated by a number of predicted potassium transporters. In “*Ferrovum*” sp. JA12 cytoplasmic buffering may be accomplished by amino acid decarboxylases or the production of polyphosphates and spermidine. The presence of a urease encoding gene cluster was unexpected since there are so far no similar gene clusters in other acidophilic iron oxidisers. “*Ferrovum*” sp. JA12 may use the urease to create a cytoplasmic buffering system similar to the pathogenic neutrophile *Helicobacter pylori*. Furthermore, the genome contains numerous genes encoding chaperones and DNA repair systems to cope with damages to proteins and DNA caused by low pH. Taken together “*Ferrovum*” sp. JA12 uses strategies to inhibit uncontrolled influx of protons, to cope with excess protons and to deal with cellular damages in order to maintain life in acidic environments.

## FEMS-2099

### Archaea and life in extreme environments

## SYSTEMS BIOLOGY X-TREME: METABOLISM AND ITS CHALLENGES AT HIGH TEMPERATURE

B. Siebers<sup>1</sup>, T. Kouril<sup>1</sup>

<sup>1</sup>Faculty of Chemistry Biofilm Centre, University of Duisburg-Essen, Essen, Germany

### Background

**Background.** Archaea are characterized by a complex metabolism with many unique enzymes that differ from their bacterial and eukaryotic counterparts. *Sulfolobus solfataricus* (optimal growth at 80°C, pH 3) is known for its metabolic versatility and is able to utilize a great variety of different carbon sources (e.g. polymers, pentoses, sugar acids, aldehydes). However, the underlying degradation pathways and their regulation are largely unknown.

### Objectives

**Objectives.** In the SulfoSYS<sup>BIOTEC</sup> project we analyse growth on different carbon sources using an integrated Systems Biology approach. Besides pathway elucidation metabolic constraints for life at high temperature due to metabolite instability are of special interest.

### Methods

**Methods.** Systems Biology approaches (genomics, transcriptomics, proteomics, metabolomics, bioinformatics, modelling, classical microbiology, biochemistry as well as genetic/ molecular biology techniques).

### Conclusions

**Conclusions.** Using a combined modelling and *in vitro* reconstruction approach it could be shown that in *S. solfataricus* the thermal instability of triosephosphates leads to carbon loss and futile cycling. Like in the modified branched Entner-Doudoroff pathway for D-glucose degradation also in the newly discovered pathway for L-fucose the formation of triosephosphates is omitted ((i) L-fucose oxidation to L-fuconate via a promiscuous dehydrogenase, (ii) dehydration to 2-keto-3-deoxy-L-fuconate via dehydratase, (iii) 2-keto-3-deoxy-L-fuconate cleavage to pyruvate and L-lactaldehyde via aldolase and finally (iv) L-lactaldehyde conversion to L-lactate via aldehyde dehydrogenase). This pathway shows interesting overlaps to the D-arabinose pathway representing another example for pathway promiscuity in *Sulfolobus* species. Thus, circumventing triosephosphate formation appears to be a special metabolic

thermoadaptation strategy in *Sulfolobus* to face the special challenge of metabolism at high temperature.

**PURPLE PHOTOSYNTHETIC REACTION CENTERS FOUND IN THE RARE BACTERIAL PHYLUM GEMMATIMONADETES**

M. Koblizek<sup>1</sup>, F. Feng<sup>2</sup>, H. Medova<sup>1</sup>, J. Dean<sup>1</sup>, Y. Zeng<sup>1</sup>

<sup>1</sup>Center Algatech, Inst of Microbiology, Trebon, Czech Republic

<sup>2</sup>Institute for Applied and Environmental Microbiology, Inner Mongolia Agricultural University, Huhhot, China

**Background**

Photosynthetic bacteria represent one of the earliest organisms on Earth. Despite over three billion years of evolution, organisms containing (bacterio)chlorophyll based reaction centers have so far been reported in only six out of over thirty bacterial phyla.

**Objectives**

In search for novel photosynthetic species we conducted a large screening of microorganisms inhabiting several extreme aquatic habitats.

**Methods**

One of the surveyed lakes was the Swan lake in the western Gobi Desert, Inner Mongolia, China. The screening was performed using a custom made infra-red screening system.

**Conclusions**

Using this approach we isolated a novel red pigmented strain AP64 belonging to the poorly characterized bacterial phylum Gemmatimonadetes. The new organism contains fully functional type-2 (pheophytin-quinone) photosynthetic reaction centers composed of bacteriochlorophyll *a* and carotenoids of spirilloxanthin series. Full genome sequencing revealed the presence of a 42.3-kb long photosynthesis gene cluster (PGC) in its genome. This makes Gemmatimonadetes the seventh bacterial phylum containing chlorophototrophic species (after Cyanobacteria, Proteobacteria, Chlorobi, Chloroflexi, Firmicutes and Acidobacteria). The organization and phylogeny of its photosynthesis genes suggested their ancient acquisition via horizontal transfer from purple phototrophic bacteria. It challenges our understanding of the evolution of photosynthesis providing the first evidence that photosynthetic capacity can be transferred between distant bacterial phyla.

**Toxin-antitoxin systems in bacteria: clinical implications**

**Role of TA modules in *Salmonella* persists during infection**

S. Helaine<sup>1</sup>, A. Cheverton<sup>1</sup>

<sup>1</sup>CMBI, Imperial College London, London, United Kingdom

Bacterial persisters are generally non-growing cells that are tolerant to antibiotic treatment. They have been studied mainly in *Escherichia coli in vitro* and are reported to form stochastically at very low frequency. All bacterial species form persisters and they are particularly relevant in the context of chronic infections that are recalcitrant to antibiotic treatment. *Salmonella enterica* causes acute and chronic infections by replicating and surviving for long periods of time within host cells, notably macrophages. Previously we described a dual fluorescence reporter method, Fluorescence Dilution, which enables heterogeneity of intracellular bacterial replication to be followed at the single cell level. Using this method we found many viable non-replicating bacteria in several organs in the mouse model of typhoid caused by *Salmonella*. We provide evidence that interaction with the host triggers formation of intracellular persisters that are likely to constitute a reservoir for relapse of infection by *Salmonella* and we decipher the host triggering signals and the bacterial actors involved in this phenomenon.

**FEMS-2816**

## **Toxin-antitoxin systems in bacteria: clinical implications**

### **Type II toxin-antitoxin systems: a reservoir for more sophisticated functions?**

L. Van Melderen<sup>1</sup>

<sup>1</sup>*Laboratoire de Génétique et Physiologie Bactérienne - IBMM,  
Université Libre de Bruxelles, Gosselies, Belgium*

### **Background**

Type II toxin-antitoxin systems (TAs) are composed of two genes that encode a toxic protein and its cognate antitoxin. TAs are surprisingly abundant in bacterial and archeal genomes. The reason of this evolutionary success remains largely unknown. Such 'toxin-antitoxin-like' functions are also found in complex secretion systems targeting bacterial or eukaryotic cells and relying on secreted toxins.

### **Objectives**

Our hypothesis is that type II toxic domains are recruited by genetic systems encoding sophisticated functions such as type III, IV and type VI secretion systems as well as bacterial contact-dependent growth inhibition system (CDI and Rhs).

### **Methods**

Using bioinformatics approaches, a series of domain of unknown function (DUF) was detected in bacterial genomes and predicted to be *bona fide* toxins belonging to TAs and to be associated with CDI and/or Rhs or to be homologous to effectors of type III secretion systems. Functionality of putative toxic domains and antitoxin/immunity is tested in *E. coli*. Toxin activity and targets are investigated.

### **Conclusions**

Our data show that domains from TAs or CDI/Rhs systems or homologous to type III effectors are toxic for *E. coli* and that toxicity is rescued by co-expression of the antitoxin/immunity cognate protein. These domains were shown to inhibit translation, although through different means, suggesting that new targets might be possibly involved.

In conclusion, recruitment of toxic domains encoded by TAs by secretion systems might constitute a strong selective pressure. This may provide an explanation why TAs are evolutionary successful and widespread in bacterial genomes.

<sup>2</sup>Molecular and Cellular Biology of Intracellular Bacterial Pathogens,  
Centro Nacional de Biotecnología (CNB), Madrid, Spain

**Background**

*Salmonella enterica* serovar Typhimurium (S. Typhimurium) is a Gram-negative bacteria which can infect and proliferate within several eukaryotic cells lines. This pathogen can persist in the infected organisms during a prolonged period of time and is responsible for human diseases ranging from gastroenteritis to systemic disease. This species, as most bacteria, possesses Toxin-Antitoxin Systems (TAS) in its genome. TAS are operons composed of two genes: an unstable antitoxin and a stable toxin, which can be activated in response to different stress conditions. The toxins targets are important for cell proliferation or viability. In this way, TAS can regulate bacterial cell growth and can induce biofilm formation, persistence, and probably dormancy during infections.

**Objectives**

To characterize TAS of S. Typhimurium and measure their role in infection.

**Methods**

TAS search was done using different data bases. Three different cell lines (two types of fibroblasts and HeLa cells) were selected for infection assays. Intracellular TAS expression was monitored by proteomics and RT-qPCR.

**Conclusions**

We report a systematic survey and functional analysis of TAS found in S. Typhimurium. Our analyses showed that 18 out of 27 identified TAS of S. Typhimurium are *bona fide* systems. Although we could detect expression of 10 TAS under eukaryotic cell infection, only 5 systems (3 type I and 2 type II modules) contributed to intracellular survival.

**Background**

The diverse and abundant proteins containing FIC (filamentation induced by cAMP) domains typically perform AMPylation, the transfer of an adenosine-5' monophosphate onto target proteins. Research has so far focused on scattered representatives that secondarily evolved into bacterial virulence factors, but their original functions and evolutionary trajectories have remained elusive.

**Objectives**

We studied the molecular function and biological role of bacterial FIC domain proteins that are related to host-targeted effector proteins of *Bartonella* in order to understand their evolution.

**Methods**

We used protein biochemistry and proteomics to identify the molecular function of bacterial FIC domain proteins. Classical microbiology and advanced agarose gel electrophoresis were used to study the effects of these proteins inside bacterial cells, particularly on DNA topology.

**Conclusions**

One major group of bacterial FIC domain proteins are toxins of a novel toxin-antitoxin (TA) module that acts via the AMPylation of DNA gyrase and topoisomerase IV, the two bacterial type IIA topoisomerases. AMPylation inhibits all activities of the targets and thus causes a disruption of cellular DNA topology that induces bacterial persistence, a dormant state of multidrug tolerance. One of these FIC domain toxins, VbhT, is encoded next to a type IV secretion system (T4SS) in *Bartonella* and unique

in that it contains a cognate secretion signal. This protein and the associated T4SS are closely related to host-targeted effectors of this widespread mammal pathogen and their secreting machinery. We therefore propose that VbhT is an interbacterial effector protein and constitutes a “missing link” in the evolution of host-targeted effectors from genuine bacterial proteins.

<sup>1</sup>*Microbiële en Moleculaire Systemen, KU Leuven, Heverlee, Belgium*

**Background**

Within a bacterial population, a small fraction of persister cells is transiently capable of surviving exposure to lethal doses of antibiotics. As a bet-hedging strategy, persistence levels are determined both by stochastic induction and by environmental stimuli, called responsive diversification.

**Objectives**

Our results support a central role for the conserved GTPase Obg in determining persistence in *Escherichia coli* in response to nutrient starvation. In this work we unravel the underlying molecular mechanism.

**Methods**

We used single cell methods to correlate Obg levels with persistence and identified the stringent response as a contributing pathway by using knockout strains. Furthermore, we performed a transcriptome study to identify downstream genetic elements. This resulted in the identification of HokB, a pore-forming toxin and part of a toxin/antitoxin module, as an effector of Obg-mediated persistence. To assess the role of HokB in this phenomenon, we showed membrane depolarization upon *obg* and *hokB* overexpression. Furthermore, repolarization of the bacterial membrane by means of a light-driven proton pump diminishes the effect of Obg and HokB on persistence, demonstrating a causal link between the membrane potential and the persistence phenotype.

**Conclusions**

We propose a model for Obg-mediated persistence that requires the stringent response alarmone (p)ppGpp and proceeds through transcriptional control of the *hokB-sokB* type I toxin-antitoxin module. In individual cells, increased Obg levels induce HokB expression, which in turn results in a collapse of the membrane

potential, leading to dormancy. Combined, our findings signify an important step towards unravelling genetic mechanisms underlying persistence.

**Toxin-antitoxin systems in bacteria: clinical implications**

**MOLECULAR BASES OF THE ALLOSTERIC SWITCH IN CONDITIONAL COOPERATIVITY REGULATION OF TOXIN-ANTITOXIN OPERONS**

A. Garcia-Pino<sup>1</sup>, R. Loris<sup>2</sup>

<sup>1</sup>*Department of Molecular Biology, Free University of Brussels (ULB), Gosselies, Belgium*

<sup>2</sup>*Department of Molecular and Cellular Interactions, Vrije Universiteit Brussel, Brussels, Belgium*

**Background**

Conditional cooperativity is the paradigm of transcription regulation of type II toxin-antitoxin (TA) operons and is intricately related to persistence. Conditional cooperativity allows the toxin component of toxin-antitoxin modules to act as a co-repressor at low toxin:antitoxin ratios and become an activator at high toxin:antitoxin ratios. A common feature in the majority of antitoxins is the presence of an intrinsically disordered region (IDR) typically involved in toxin neutralization and repressor complex formation.

**Objectives**

To address how the antitoxin IDR is involved in transcription regulation, using the *phd/doc* operon as model system.

**Methods**

We determined crystal structures of Phd in complex with its operator box. The DNA-binding domain of Phd interacts with DNA in a novel fashion. Moreover thermodynamic and structural characterization of Phd in complex with the operator region of the operon in different repression states reveals that a phenotypic switch from negative to positive cooperativity, involving the IDR, is the core of the regulatory process.

**Conclusions**

In absence of Doc, the intrinsically disordered part of the repressor bound to the DNA acts as a "veil" covering the second site and precluding the binding of a second Phd molecule, resulting in strong negative cooperativity and weak repression. The presence of Doc drives the folding upon binding of the additional Phd molecule with the consequent increase in affinity and strengthening repression, up to the point when the excess of Doc overwhelms the system leading to its de-repression. Our model has important implications in the regulation of bacterial operons involving intrinsically disordered transcription factors.

**Fungal bacterial interactions**

**Microbial logistics - Mycelia as networks for functional transport of bacteria and chemicals**

L. Wick<sup>1</sup>

<sup>1</sup>*Environmental Microbiology, Helmholtz Centre for Environmental Research - UFZ, Leipzig, Germany*

Biodegradation of contaminants in soil is a logistic problem. 'Logistics'; refers to have 'the right thing, at the right place, at the right time'. Degrading bacterial communities walk the tightrope of contaminant availability and suitable physical habitats for their metabolic activity; this situation is often aggravated by the concurrence of restricted bacterial mobility and retarded transfer of hydrophobic organic contaminants (HOC). In order to cope with heterogeneous soil environments mycelial fungi therefore have developed a unique network-based growth form. Unlike bacteria mycelia spread efficiently in the soil, penetrate air-water interfaces and cross over air-filled pores between the bacteria and contaminants in the vadose. In air-filled soil, enhanced homogenization of bacteria and contaminants can be achieved by bridging physical air gaps with fungal hyphae thus enabling substrate-directed mobilization of bacteria along chemical gradients. In this contribution we demonstrate the biodegradation-enhancing influence of mycelial dispersal networks on both the microbial transport and the translocation of HOC. Here we show that mycelial networks (i) act as effective dispersal networks for both undirected and targeted mobilization of contaminant degrading bacteria ('fungal highways'), (ii) act as hotspots for horizontal gene transfer, (iii) increase the mobility of a wide range of HOC due to their translocation in their cytoplasmic streaming ('fungal pipelines'), and (iv) improve the accessibility of bacteria to soil contaminants and their subsequent biodegradation. Given their ubiquity and length of up to  $1000 \text{ m g}^{-1} \text{ dry soil}$  mycelia may play a significant role for the ecosystem service of contaminant biodegradation. Knowledge of 'logistic fungus bacteria interactions' may also be exploited in biotechnological approaches beyond soil remediation, such as in food industry or the production of biofuels.

Although the role of fungi and bacteria in processes such as decaying or nutrient cycling in soils has been established, the part played by the interactions between these microbial taxa in soil functioning is still poorly known. Myriads of potential interactions can emerge as results of the encounter of fungi and bacteria in a shared environment. These interactions range from positive (e.g. mutualism) to negative (e.g. antagonism). I will present results for several of these types of interactions including fungus-driven bacterial dispersal, bacterial farming by fungi, as well as biocontrol and niche exclusion between bacteria and fungi. For those, we have started to understand the underlying principles that have allowed the emergence and maintenance of these interactions within an evolutionary conceptual frame. In addition, we are investigating the molecular and chemical mechanisms that regulate processes such as partner recognition or metabolic activity. All of these elements are addressed in the context of the importance of fungi-bacteria interactions in ecosystem functioning and services, in particular related to pedogenic carbon storage.

In the past few years, the scientific community has started to recognize the importance of fungi-bacteria interactions in fields as varied as human health (e.g. infection and obesity), agriculture (e.g. plant growth promotion), or the environment (e.g. carbon storage and nutrient cycling). In the future it will be important to compare the mechanisms discovered in the case of soil fungi-bacteria interactions with other ecosystems, in order to understand the universality of the processes that allow these phenomena to emerge in nature.

**EFFECT OF DISPERSAL NETWORKS ON BACTERIAL DISPERSAL AND BIODEGRADATION AT VARYING WATER POTENTIALS**

A. Worrich<sup>1</sup>, M. Kästner<sup>2</sup>, A. Miltner<sup>2</sup>, L.Y. Wick<sup>1</sup>

<sup>1</sup>*Environmental Microbiology, Helmholtz Centre for Environmental Research, Leipzig, Germany*

<sup>2</sup>*Environmental Biotechnology, Helmholtz Centre for Environmental Research, Leipzig, Germany*

**Background**

In porous media the matric and the osmotic potential contribute to the availability of water to microbes and decisively influence important microbial ecosystem services such as biodegradation. Bacterial motility is considered as a key driver for biodegradation and fungal mycelia have been shown to serve as effective dispersal networks thereby increasing bacterial movement in water unsaturated environments.

**Objectives**

However, poor knowledge exists on the beneficial effects of mycelia at varying water potentials ( $\Psi_w$ ).

**Methods**

We therefore established experimental microcosms to investigate the effect of mycelia-like dispersal networks on the dispersal and growth of *Pseudomonas putida* KT2440-gfp at given osmotic and matric potentials and determined their benefit for the biodegradation of benzoate. Using either NaCl or polyethylene glycol 8000 the  $\Psi_w$  of agar was modified between  $\Delta\Psi_w$  0 - -1.5 MPa (i.e. water potentials representing completely saturated or plant permanent wilting point conditions).

**Conclusions**

We found that dispersal, growth and biodegradation rates dropped noticeably below  $\Delta\Psi_w$  -0.5 MPa in osmotically stressed systems. However, in matric stress treatments this decline occurred at  $\Delta\Psi_w$  -0.25 MPa due to a complete repression of bacterial movement at this  $\Psi_w$ . The presence of dispersal networks effectively defused the negative effects of lowered matric potentials by enhancing bacterial dispersal. No beneficial network effect was observed in the osmotically stressed systems, likely due to NaCl toxicity rather than the water deprivation effects. We propose that dispersal networks act as an important buffer mechanism and hence may increase the microbial ecosystem's functional resistance to matric stress.

## **STRATEGIES OF STREPTOMYCETES FOR FUNGAL TARGETING AND INHIBITION**

H. Schrempf<sup>1</sup>, P. Merling<sup>1</sup>

<sup>1</sup>FB Biologie/Chemie, University of Osnabrück, Osnabrück, Germany

### **Background**

Streptomyces belong to actinobacteria, have a complex life cycle, and comprise many species. They have a large linear chromosomal DNA, which has been sequenced from many species. They are highly abundant in different soil-types and the rhizosphere of plants. They can play a role in association with selected organisms, and sometimes as symbionts. The knowledge about proteins and compounds facilitating these interactions is still scarce.

### **Objectives**

The aim of the presented investigations was to investigate the role of newly discovered proteins and vesicles during the interaction of streptomyces with selected fungi.

### **Methods**

Characterization of proteins and metabolites using LC-MS, electron-microscopy, fluorescence microscopy, cloning of genes, and analyses of designed mutants.

### **Conclusions**

Streptomyces produce several unique proteins that target selected fungi provoking close interaction. We purified the proteins and elucidated their mode of action.

In addition, we discovered firstly that several proteins and metabolites of streptomyces reside in vesicles, which we characterised by several biochemical and microscopic tools. We succeeded to monitor the in vivo generation of vesicles and to propose of a model for their biogenesis. The application of vesicles to selected fungi including a plant pathogen, led to pronounced fungal damages. The investigations revealed the sophisticated *Streptomyces* repertoire to target and to suppress fungi

including a plant pathogen.

<sup>1</sup>Department of Food Science, University of Copenhagen, Copenhagen, Denmark

<sup>2</sup>Nutrition Biosciences ApS, DuPont, Brabrand, Denmark

**Background**

Fungi constitute a major spoilage problem in many foods including dairy products. The use of specific lactic acid bacteria (LAB) with antifungal properties has shown potential for delaying fungal spoilage without compromising sensory acceptability of the products. Much effort has been put into isolating and identifying antifungal metabolites from active fractions of cell free ferments of these bacteria. However, the methods used have been suboptimal for detection of volatiles.

**Objectives**

To study the antifungal role of volatiles.

**Methods**

Inhibitory effect of a *Lactobacillus paracasei* and metabolites was studied in a newly developed chemically defined medium and yogurt against two spoilage-associated *Penicillium* strains using a gentle sample treatment.

**Conclusions**

Diacetyl was identified as the major volatile produced. Antifungal activity was observed in both solid and liquid media as well as in yogurt. If cells were removed from the ferment both diacetyl content and antifungal activity was drastically reduced. If formation of diacetyl was inhibited by enzymatic conversion of the pre-cursor antifungal activity decreased markedly underlining the importance of volatile compounds in the inhibitory activity.

### **THE 'FUNGAL HIGHWAY' TOLL: METABOLISMS AND GENES INVOLVED IN FUNGAL-DRIVEN BACTERIAL DISPERSAL IN NATURAL ECOSYSTEMS**

A. Simon<sup>1</sup>, A. Al-Dourob<sup>1</sup>, S. Bindschedler<sup>1</sup>, L.Y. Wick<sup>2</sup>, J. Zopff<sup>3</sup>, D. Job<sup>1</sup>, E.P. Verrecchia<sup>4</sup>, P. Junier<sup>1</sup>

<sup>1</sup>Laboratory of Microbiology, University of Neuchâtel, Neuchâtel, Switzerland

<sup>2</sup>Department of Environmental Microbiology, Helmholtz Centre for Environmental Research - UFZ, Leipzig, Germany

<sup>3</sup>Department of Environmental Sciences, University of Basel, Basel, Switzerland

<sup>4</sup>Biogeosciences laboratory, University of Lausanne, Lausanne, Switzerland

#### **Background**

Bacterial motility in water-unsaturated soil is usually highly restricted. Previous experiments *in vitro* however have demonstrated that bacteria may take the 'fungal highway', i.e. are able to actively move along fungal hyphae.

#### **Objectives**

In order to get better insights into such fungal-bacterial interactions *in situ*, we developed a column system designed to collect and cultivate fungi and associated migrator bacteria at varying growth conditions.

#### **Methods**

Our column system was placed into a soil known to exhibit high metabolic fungal-bacterial interactions within the oxalate-carbonate pathway. After 4 to 8 days, the columns were removed, bacteria and fungi that grew in the columns identified, and the bacteria analyzed for their ability to use different carbon sources, fix nitrogen and to encode the type-III secretion system (as possible indicator for migrating activity along hyphae).

#### **Conclusions**

We identified *Fusarium* sp. and *Chaetomium* sp. as fungi, and *Achromobacter* sp., *Acinetobacter calcoaceticus*, *Ochrobactrum* sp., *Olivibacter* sp., *Pseudomonas* sp., *Stenotrophomonas* sp. and *Variovorax* sp. as associated migrator bacteria. We found that the ability of bacteria to move along their fungal hosts was medium-dependent. Most of the bacteria were able to fix dinitrogen. This points to a possible trophic exchange between bacteria and fungi. Except for one bacterial strain genes encoding type-III secretion systems were not found in the isolated bacteria.

Our findings propose that fungal hyphae are not an inert path taken by motile bacteria; 'fungal highways' interactions seem to be mediated by trophic exchanges between fungi and bacteria. Therefore, migrator bacteria selection might be based on their metabolic capabilities.

**Natural products including secondary metabolites**

**Metabolically talented bacteria from microbial dark matter**

J. Piel<sup>1</sup>

<sup>1</sup>*Institute of Microbiology, ETH Zurich, Zurich, Switzerland*

Environmental studies suggest that a large fraction of the total bacterial diversity has so far resisted cultivation. Many of the uncultivated bacteria belong to large taxonomic groups without cultivated representatives and known functional properties. Considering the importance of bacteria for drug discovery, it has been proposed that these elusive organisms represent a massive untapped resource of novel compounds and biotechnologically useful enzymes. To investigate the biosynthetic potential of microbial dark matter, our laboratory uses metagenomic and single-cell methods focusing on host-associated microbiomes. We provide evidence for the existence of a new environmental candidate phylum, termed "Tectomicrobia", members of which live associated with marine sponges and are metabolically highly versatile. These bacteria exhibit a rich specialized metabolism with bioactive compounds not yet encountered in cultivated microbes. Functional studies revealed unprecedented types of biosynthetic transformations that are of significant biotechnological interest.

#### **High-throughput chemotyping and phenotyping using *Pseudomonas aeruginosa* deletion libraries**

M. Banzhaf<sup>1</sup>, A. Typas<sup>1</sup>

<sup>1</sup>Genome Biology, EMBL, Heidelberg, Germany

We are currently profiling two *P. aeruginosa* single-gene deletion libraries (in the clinically relevant strains, PA01 and PA14) in a large number (>200) of chemical and environmental stresses. In these assays, we obtain quantitative measurements both for the fitness, the ability of each mutant to form biofilms and their secondary metabolite profile.

The quantitative phenotypic and chemotypic signature for each mutant will be later used to a) identify novel gene function; b) map metabolic pathways c) map interconnections between functional processes; d) address the role of horizontal gene transfer in network rewiring and gene repurposing; d) understand how chemical perturbations effect the secondary metabolite profile; e) identify novel secondary metabolites; etc.

At the workshop I will present the basis of our methodology, a progress report on the ongoing screen and proof-of-principle examples highlighting the different types of information we are obtaining. Another aspect of the talk will be how to handle and mine such a diverse data set (<16k MS&MS2 profiles, <12800k independent phenotypic data points).

<sup>3</sup>*School of Biomedical Sciences, Curtin University, Perth, Australia*

<sup>4</sup>*Department of Microbiology, University College Cork, Cork, Ireland*

**Background**

The increase in antibiotic resistance among clinical microbes has created a need to develop antimicrobials with novel modes of action.

**Objectives**

As part of a marine biodiscovery programme, sponge-associated microbes were screened to identify novel metabolites.

**Methods**

Metabolomics and genomics are two complementary platforms for analysing an organism as they provide information on the phenotype and genotype, respectively. These two techniques were applied in the dereplication and identification of bioactive compounds from a *Streptomyces* sp. (SM8) isolated from the sponge *Haliclona simulans* from Irish waters. Three distinct bioactives that include an antibacterial fatty acid derivative, and separate antifungal and anti-calcineurin activities were identified. Antimycin compounds were identified in the antifungal fractions. Genomic analysis revealed the presence of multiple secondary metabolism gene clusters, including a cluster for the antimycin family of compounds. When the extract of the mutant strain was analysed, it showed loss of antimycin production and significantly less antifungal activity than the wild-type strain. Butenolides were identified as compounds showing anti-calcineurin activity<sup>1</sup>.

**Conclusions**

The combined metabolomic and genomic approach used in this study resulted in the identification of antimycins, polyhydroxylated saturated fatty acids and butenolides as

major antifungal and antibacterial and anti-calcineurin metabolites of SM8, respectively. The genome sequence provides a genetic framework to study their biosynthesis and their potential role in regulation of gene expression.

## **MOLECULAR GENETICS OF SIMOCYCLINONES BIOSYNTHESIS: SURPRISING ASSEMBLY OF THE TETRAENE CHAIN**

O. Bilyk<sup>1</sup>, E. Brötz<sup>1</sup>, T. Paululat<sup>2</sup>, A. Luzhetskyy<sup>1</sup>

<sup>1</sup>AMEG, Helmholtz Institute for Pharmaceutical Research, Saarbrücken, Germany

<sup>2</sup>Fakultät IV Organ. Chemie 2, Universität Siegen, Siegen, Germany

### **Background**

Simocyclinone D8 and its' derivatives were isolated from *Streptomyces antibioticus* Tü6040. They exhibit antibiotic activity against Gram-positive and Gram-negative bacteria, and are highly potent inhibitors of DNA gyrase supercoiling with an IC<sub>50</sub> lower than that of novobiocin<sup>1,2</sup>.

### **Objectives**

However, biosynthetic studies and bioengineering of simocyclinones were limited because of difficulties in genetic manipulations of the producer strain. We have discovered the new strain *Kitasatospora* sp. producing novel simocyclinone.

### **Methods**

*Kitasatospora* sp. genome was sequenced and detailed *smc* cluster annotation has been performed as well as its alignment to published *sim* gene cluster from *S. antibioticus* Tü6040<sup>3</sup>. Inactivation and heterologous expression of several biosynthetic genes have been performed to prove their function.

### **Conclusions**

Several significant differences in the architecture of the new *smc* gene cluster have been found in comparison to the previously published *sim* gene cluster from *S. antibioticus* Tü6040. Most striking, genes responsible for the tetraene chain formation (type I PKS in *sim* cluster) could not be detected. Instead, three genes with the high similarity to ACP and two beta-ketoacyl-synthases were annotated within the *smc* cluster (*ORF2*, *ORF3* and *ORF4*, respectively).  $\Delta$ *ORF4* mutant was deficient in production of the D-type simocyclinones, only angucyclines with the attached sugar could be detected. Subsequent complementation of the mutant with the intact *ORF4* restored biosynthesis of simocyclinones. Furthermore, inactivation of the KS domen in type I PKS from *sim* cluster in *S. antibioticus* Tü6040 didn't influence biosynthesis of the simocyclinone D8. Obtained data suggest new unusual pathway for linear polyketide assembly during simocyclinone biosynthesis.

#### HETEROLOGOUS PRODUCTION OF ANTIBACTERIAL SECONDARY METABOLITES FROM *SERRATIA MARCESCENS* IN *PSEUDOMONAS PUTIDA*

A. Loeschcke<sup>1</sup>, S. Thies<sup>1</sup>, J. Hage-Hülsmann<sup>1</sup>, A. Grünberger<sup>2</sup>, D. Binder<sup>1</sup>, A. Domröse<sup>1</sup>, A. Klein<sup>3</sup>, D. Kohlheyer<sup>2</sup>, J. Pietruszka<sup>3</sup>, K.E. Jaeger<sup>1</sup>, T. Drepper<sup>1</sup>

<sup>1</sup>Institute of Molecular Enzyme Technology, Forschungszentrum Jülich, Jülich, Germany

<sup>2</sup>Institute of Bio- and Geosciences, Forschungszentrum Jülich, Jülich, Germany

<sup>3</sup>Institute of Bioorganic Chemistry, Forschungszentrum Jülich, Jülich, Germany

#### Background

Microorganisms produce a huge variety of secondary metabolites that often exhibit several valuable bioactivities such as antibiosis. This wealth is often accessed by heterologous biosynthesis in a host microbe. Several challenges are typically encountered here, concerning i) the establishment of the genetic information underlying a biosynthetic pathway, ii) the complex biosynthesis and iii) the host's tolerance towards antibiotic products.

#### Objectives

*Pseudomonas putida* is an outstanding host candidate for the heterologous production of substances with antimicrobial activity. The strain *P. putida* KT2440 is a well-established "safety strain" which is amenable to genetic modification, possesses a versatile metabolic background and withstands many antimicrobial compounds with high tolerance.

Here, we aimed to produce the secondary metabolites prodigiosin and serrawettin W1 from *Serratia marcescens*. Besides other highly valuable properties such as anticancer activity, both the tripyrrolic red pigment prodigiosin and the lipopeptide serrawettin W1 exhibit antibacterial activity, rendering their heterologous production challenging.

#### Methods

For heterologous production of prodigiosin, the entire prodigiosin gene cluster was inserted into the chromosome of *P. putida*. For the production of serrawettin W1, a single synthase gene was expressed from a plasmid in the host. Products were isolated and antimicrobial activities were verified.

## Conclusions

We successfully established production of the two antibacterial natural products prodigiosin and serrawettin W1 in the bacterial host *P. putida*, thereby enabling further studies on their bioactivities. This study further highlights that *P. putida* is highly suited for the expression of complex secondary metabolite pathways and the efficient production of antimicrobial compounds.

<sup>3</sup>*Division of Gastroenterology and Hepatology, Medical University of Graz, Graz, Austria*

**Background**

*Klebsiella oxytoca* is a natural resident of the human gut microbiota. During antibiotic-induced intestinal dysbiosis colonic overgrowth of this bacterium rapidly leads to antibiotic-associated hemorrhagic colitis (AAHC). We have shown that bacterial production of the secondary metabolite tilivalline, which is structurally related to pyrrolobenzodiazepines, induces apoptosis of epithelial cells, disrupts their barrier function, and is key to the pathogenesis of colitis in an animal model of AAHC (1). The impact of tilivalline on host physiology in healthy carriers of low (commensal) levels of *Klebsiella oxytoca* is unknown.

**Objectives**

We synthesized tilivalline chemically to investigate the human cellular processes altered by this enterotoxin in vitro.

**Methods**

HeLa cells were treated with a range of tilivalline concentrations and cellular stress responses were monitored on the transcriptional level using qRT-PCR, the protein level via Western analysis, through microscopic imaging and FACS as well as by biochemical analysis.

**Conclusions**

Apoptosis is induced by high doses of tilivalline. Low concentrations of the cytotoxin inhibit HeLa cell proliferation. The position of cell cycle arrest was defined via quantification of cyclin transcripts, DNA damage response markers, modulation of checkpoint pathways, analysis of spindle apparatus formation and centrosome dynamics.

## **FEMS-3093**

### **New diagnostic approaches**

#### **Rapid antimicrobial susceptibility testing : will it be genotypic or phenotypic?**

J. Schrenzel<sup>1</sup>

<sup>1</sup>*Dpt of Medical Specialties Dpt of Genetics and Lab Medicine,  
Bacteriology and Genomic Research Labs, Geneva, Switzerland*

#### **Rapid antimicrobial susceptibility testing: will it be genotypic or phenotypic?**

Clinicians are used to get sequential results from the microbiology lab.

For blood cultures, it is classical to report as soon as possible the presence of growth and the morphology of the bacteria that are observed under the microscope (e.g. Gram-negative rods), then an identification (e.g. *E. coli*) and finally the antimicrobial susceptibility profile, AST (e.g. amoxillin R, co-amoxicillin S, etc...). The clinician learns therefore several clinically-relevant elements, on a sequential manner, typically over a few days: i) there is bacterial growth in this sample, ii) the identification of the bacteria may suggest a particular anatomic source (e.g. likely from urinary or digestive origin), and finally, iii) the AST permits reducing the antibiotic spectrum.

MALDI-TOF MS has allowed reducing the time for bacterial identification, but this is typically insufficient to permit targeted antimicrobial therapy. There is therefore a major incentive in knowing as soon as possible how to better target antimicrobial therapy.

Sequencing (and especially with the availability of bench-top NGS systems) can provide an extensive listing of DNA sequences that are present in a sample. Irrespective of the numerous technical challenges (sample preparation, DNA extraction/purification, DNA sequencing, data analysis with or without assembly, etc...), sequence interpretation remains a major hurdle, and can also fail to capture bacterial properties affecting the AST (e.g. the activity of an extrusion pump, ...). Clinically-relevant diagnostic devices may therefore need -at least in the initial phase- to be coupled with some advanced phenotypic information of diverse nature (peptides, mRNA, enzymatic activity, etc...).

This strategy and possible implementation will be discussed during the lecture.

## **FEMS-2619**

### **New diagnostic approaches**

#### **Whole genome sequencing as a tool for clinical diagnostics**

H. Hasman<sup>1</sup>

<sup>1</sup>*Genomic Epidemiology, DTU - National Food institute, Kgs. Lyngby, Denmark*

The introduction of Whole Genome Sequencing (WGS) through the Next Generation Sequencing (NGS) technology has great potential as a typing as well as a diagnostic tool in the clinical laboratory. In principal, WGS data contain all relevant information for typing and diagnostic analysis. Existing gene based (local) typing and diagnostic data are often easily extracted from WGS data and many studies have shown the potential of WGS data for (global) analysis of clonal relationship in outbreaks. However, a prerequisite for the transition from current typing and diagnostic methods to methods based on WGS data is to identify the added value of this transition such as increased speed of analysis, decreased costs as well as cheap (free) and user-friendly harmonised WGS-based tools. Also, it will to some extent require the establishment of backward compatibility with existing typing methods, which are currently well-established tools for both clinical and epidemiological investigations. In addition to this, great efforts in relation to standardization and validation of WGS tools as well as harmonization of methods will be a requirement for a successful transition. Finally, WGS has the potential to detect and possibly type pathogens directly in complex samples (the so-called *metagenomics*), rather than analysing and comparing single isolates. The benefits from this include decreased time for diagnostics and the ability to detect pathogens, which are not easily detected by standard laboratory methods. However, tools and methods to analyse metagenome data is still in their infancy and will require further maturation before implementation directly in a clinical setting.

**FEMS-0870**

**New diagnostic approaches**

**AN INTEGRATED ANALYSIS WITH DEEP-SEQUENCING OF BACTERIAL INFECTION AND PROTEOMIC PROFILING OF NEUTROPHILS IMPROVES PREDICTION OF CLINICAL OUTCOMES IN SEPSIS**

Q. Li<sup>1</sup>, C. Wang<sup>1</sup>, C. Tang<sup>1</sup>, X. Zhao<sup>1</sup>, L. Cai<sup>1</sup>, Q. He<sup>1</sup>, J. Li<sup>1</sup>

<sup>1</sup>Department of General Surgery,

Research Institute of General Surgery Jinling Hospital Nanjing University, Nanjing, China

**Background**

Sepsis is a life-threatening complication caused by a serious microbial infection. Due to the complexity of the sepsis response, the prognosis of sepsis is poor and outcomes in individual patients are difficult to predict.

**Objectives**

This study aims to define molecular signatures of bacterial infection at various stages of sepsis progression and associate them with the clinical features and outcomes of sepsis patients.

**Methods**

Two thousand three hundred forty-three patients who underwent elective general surgery were recruited prospectively at Jinling Hospital in China from June 2013 to September 2014. A set of 180 patients had six groups that reflected conventional concepts of sepsis progression as a pyramid. Molecular patterns of bacterial infection were elucidated by 16S rDNA-based high-throughput sequencing techniques. We also performed a comparative proteomic profiling on neutrophils derived from peripheral blood of the patients.

**Conclusions**

The bacterial profiles of patients who were diagnosed as sepsis and ultimately died within 28 days differed markedly from those of survivors with sepsis. The different taxa of bacterial profiling clustered into the following genus: *Escherichia/Shigella*, *Stenotrophomonas*, *Acinetobacter*, *Pseudomonas*, *Corynebacterium* and *Propionibacterium*. A total of 97 proteins were characterized as differentially expressed between nonsurvivors and sepsis survivors, indicating impaired functions of neutrophils in lysosome, chemotaxis, transmigration, phagocytosis and intracellular killing of microorganisms. Our data demonstrate that an in-depth analysis of peripheral blood bacteria with measurements of six protein molecules on neutrophils

would predict survival of sepsis patient. This algorithm may help to guide the treatment of individual patients with sepsis.

**New diagnostic approaches**

**CAMPYLOBACTER DETECTION IN POULTRY MEAT BY USING AN ORGANIC LIGHT-EMITTING DIODE BASED BIOCHIP.**

M. Manzano<sup>1</sup>, F. Cecchini<sup>1</sup>, L. Iacumin<sup>1</sup>, G. Comi<sup>1</sup>, P. Melpignano<sup>2</sup>

<sup>1</sup>Food Science, University of Udine, Udine, Italy

<sup>2</sup>Organska Elektronika, OR-EL.doo, Kobarid, Slovenia

**Background**

Nine million cases of campylobacteriosis, due to handling and/or consumption of undercooked poultry meat contaminated with *Campylobacter*, occur each year in Europe, with a cost to public health systems of about EUR 2.4 billions. The direct plating and/or enrichment culture methodologies based on the ISO 10272-1B: 2006 are the methods typically used, but the long time required by the classical methods to grow microorganisms, can lead to the distribution of contaminated food. Molecular biology with PCR, qPCR and blotting techniques have greatly improved the techniques by reducing the time required to obtain results, but integrated biochips are the ideal solution for producing portable diagnostic systems.

**Objectives**

The aim of the work was the development of a miniaturised, highly-sensitive DNA biochip based on a deep-blue organic light-emitting diode (OLED) to analyze real poultry samples.

**Methods**

Two specific DNA probes (capture and detection) were designed and used to analyze real poultry meat samples. The capture probe was bonded to a glass slide while the detection probe was labelled with a Alexa Fluor fluorophore to be detected by the utilization of the OLED.

**Conclusions**

The results obtained by the biochip were compared with PCR, broth enrichment and colony growth methods, to demonstrate the relevance of this system. The OLED biochip reached a sensitivity of 0.37 ng/μL DNA, which was approximately 20-fold higher than the sensitivity obtained with dot blot assay (25 ng/μL) and didn't need an enrichment step. This system exploits a multi-disciplinary approach, and shows high sensitivity, quick test results and ease of use.

<sup>5</sup>Departamento de Bioquímica Clínica,  
Universidad de Buenos Aires Facultad de Farmacia y Bioquímica,  
Ciudad Autónoma de Buenos Aires, Argentina

**Background**

*Treponema pallidum* subsp. *pallidum*, the causative agent of syphilis, is a sexually-transmitted disease with worldwide occurrence. Molecular typing of *T. pallidum* provides valuable epidemiological information, including determination of macrolide resistance.

**Objectives**

This study was aimed to type, for the first time in South America, *T. pallidum* isolates in clinical samples

**Methods**

During 2013, 79 samples were collected from patients with clinical signs of syphilis: 72 lesion swabs, 3 whole blood samples and 4 cerebrospinal fluid. DNA was extracted and PCR amplification of *poIA*(TP0105), *tmpC*(TP0319), TP0136, TP0548, and 23S rRNA was performed(1). A CDC typing scheme was made including the determination of 60-bp repeats in the *arp* gene, RFLP of *tprE*-G-J and sequence analysis of TP0548(2). The human MTHFR gene was amplified to test for PCR inhibitors.

**Conclusions**

Treponemal DNA was detected in 57.3%(43/75) of samples (four were excluded). A total of 36 samples (83.7%) were typed. Nine genotypes were detected using the sequencing-based typing, with SSS being the most frequent. CDC typing scheme

was done in 22 samples, and 7 genotypes were detected, with 14d/d being the most common. In 13.9% of the samples, mutations causing macrolide resistance were detected. In conclusion, during this first molecular typing study, low frequency of macrolide resistant mutations was detected compared to Europe and the US. Although some detected treponemal genotypes were identical to those described in other countries, several genotypes were new, not found outside Argentina.

### New diagnostic approaches

#### RAPID AND SENSITIVE ISOTHERMAL DNA AMPLIFICATION ON A DIGITAL MICROFLUIDIC DEVICE FOR THE DETECTION OF ANTIBIOTIC RESISTANT BACTERIA

M. Valiadi<sup>1,2</sup>, S. Kalsi<sup>1,2</sup>, R.J. Watson<sup>3</sup>, J.M. Sutton<sup>3</sup>, H. Morgan<sup>1,2</sup>

<sup>1</sup>Electronics and Computer Science, University of Southampton, Southampton, United Kingdom

<sup>2</sup>Institute for Life Sciences, University of Southampton, Southampton, United Kingdom

<sup>3</sup>Healthcare Biotechnology, Public Health England, Salisbury, United Kingdom

#### Background

Antibiotic resistance is a growing global threat to human health. There is a clear need to develop rapid and sensitive tests to determine antibiotic resistance as part of diagnosis so that antibiotics can be prescribed to treat infections in a targeted manner. The most rapid, sensitive and specific molecular assays are based on nucleic acid amplification to detect specific genes of interest. Combining this with droplet microfluidic platforms represents the most promising approach for portable point-of-care assays.

#### Objectives

To develop a miniaturised assay to detect the gene encoding for a CTX-M enzyme, an extended spectrum  $\beta$ -lactamase present in common bacteria such as *E. coli*.

#### Methods

We perform real time isothermal DNA amplification by recombinase polymerase amplification (RPA) on a digital microfluidic device, which utilises active matrix electrowetting on dielectric (AM-EWOD) technology.

#### Conclusions

The assay can detect just 10 copies of the *E. coli* CTX-M gene within 15 minutes. Continuous mixing during the assay run on AM-EWOD enhances the sensitivity of the assay by 10-fold relative to a commercial microplate reader. The assay is quantitative, with the time of onset of amplification relating to the logarithm of DNA copies in a linear manner. DNA from *E. coli* containing the CTX-M gene can be detected even when it is mixed 1:100 with genomic DNA from *E. coli* without CTX-M. Our systems ability to rapidly detect antimicrobial resistance genes represents a promising step to a complete and fully automated, sample in – answer out, Point of Care diagnostic assay suitable for directing antibiotic prescribing.

### **Protein Engineering and Enzyme Cascade Reactions**

U.T. Bornscheuer<sup>1</sup>

<sup>1</sup>Universität Greifswald

Uwe T. Bornscheuer, Universität Greifswald

Protein engineering has developed in the past decade to a highly important technology (1,2) to create enzymes with desired properties, but also to understand their function. Whereas initially rational protein design based on detailed analysis of structures was the method of choice, directed evolution became an important alternative. In this lecture, the principle strategies and current challenges in protein engineering will be highlighted. We used information from protein databases to create 'small, but smart' focused protein libraries of enzymes from the a/b-hydrolase fold family using the 3DM database (3). This resulted in enzyme variants with enhanced thermostability or enantioselectivity (4). For the synthesis of chiral amines, we developed an *in silico* analysis and identified a toolbox of novel (*R*)-selective transaminases (5) as well as (*S*)-selective enzymes from a structure-guided search (6). More recently, we focused on cascade reactions to convert unsaturated fatty acids to  $\omega$ -hydrocarboxylic acids (7), or to combine alcohol dehydrogenase, enoate reductase and monooxygenase for *in vivo* biotransformations (8). In another project, we use a chalcone isomerase in the conversion of flavonoids (9). Very recently, we developed a synthesis of  $\epsilon$ -caprolactone-oligomers through an enzyme cascade (10).

**Discovery and engineering of enzyme systems for the transformation and degradation of explosives**

N.C. Bruce<sup>1</sup>

<sup>1</sup>*Department of Biology, University of York, York, United Kingdom*

**Background.** The contamination of the environment with toxic explosives presents a serious and widespread problem at sites across the world. Our recent studies on the biodegradation of energetic compounds have resulted in the isolation of bacteria from explosive-contaminated land that are capable of metabolizing 2,4,6-trinitrotoluene (TNT) and RDX. Our work has targeted the use of genetic engineering for broadening and improving the degradative capabilities of biological systems for the remediation of explosives pollution. Significant progress has been made towards this goal and we have successfully combined the biodegradative capabilities of soil bacteria with the high biomass and stability inherent to plants. In an effort to determine how plant tolerance could be further improved, we have been investigating the enzymology underlying the innate ability of plants to detoxify explosives.

**Objectives.** 1. To determine the biochemistry and molecular genetics of explosives metabolism in microorganisms and plants. 2. To characterise the enzymes mediating these degradative pathways. 3. To engineer transgenic plant systems for the remediation of explosives contaminated land.

**Methods.** The work has required a plethora of modern molecular techniques and spans methods in microbial and plant biology through to methods in synthetic biology and enzyme engineering.

**Conclusions.** These studies have identified a number of interesting enzymes including a unique cytochrome P450 XplA from a strain of *Rhodococcus rhodochrous* that degrades RDX. We have successfully engineered transgenic plants that can efficiently remove toxic levels of TNT and RDX from contaminated soil and water. As a result of recent advances in our knowledge of the biodegradation of explosives, endogenous plant detoxification systems and the use of genetic engineering, our work on transgenic plants is now poised for testing in the field.

## **FERMENTATION OF CRUDE SYNGAS FROM THE BIOLIQ® PLANT KARLSRUHE**

*F. Oswald<sup>1</sup>, A. Neumann<sup>1</sup>*

<sup>1</sup>*Technical Biology, Karlsruhe Institute of Technology, Karlsruhe, Germany*

### **Background**

The new bioliq® pilot plant at the KIT covers the complete process chain required for producing customized fuels from dry lignocellulosic biomass. For energy densification of the biomass, fast pyrolysis is applied. The liquid pyrolysis oil and solid char obtained can be processed further in the entrained flow-gasifier to tar-free, low-methane raw synthesis gas. Prior to chemically catalysed fuel synthesis a multistep cleaning of raw synthesis gases is performed: Particles, alkaline salts, HCl, H<sub>2</sub>S, COS, CS<sub>2</sub>, NH<sub>3</sub>, and HCN are removed to avoid catalyst poisoning during fuel synthesis. The pilot plant is equipped with an innovative hot-gas cleaning system.

### **Objectives**

Acetogenic bacteria are able to ferment syngas to a variety of organic acids and alcohols. In contrast to the catalysts used in the Fischer-Tropsch process, these biological catalysts can process a broad range of syngas compositions and deal with impurities like sulphur compounds or CO<sub>2</sub>. At the moment intense efforts are made to genetically modify *C. ljungdahlii* to optimize product yields and establish synthesis routes to new products. To assess industrial large scale applicability of these strains it will be necessary to determine their performances with crude syngas, as each purifying step will decrease the economy of the process.

### **Methods**

Our aim is to establish a platform process for evaluating the use of different qualities of raw syngas obtained from the different steps of Karlsruhe bioliq® plant.

### **Conclusions**

Therefore, a setup of multiple 2 L bioreactors with online gas and product analysis is currently developed in our lab

**HIGH LEVEL PRODUCTION OF ETHYLMALONYL-COA PATHWAY-DERIVED DICARBOXYLIC ACIDS BY METHYLOBACTERIUM EXTORQUENS UNDER COBALT-DEFICIENT CONDITIONS AND BY POLYHYDROXYBUTYRATE NEGATIVE STRAINS**

F. Sonntag<sup>1</sup>, E. Gehr<sup>1</sup>, P. Kiefer<sup>2</sup>, J. Müller<sup>2</sup>, J. Vorholt<sup>2</sup>, J. Schrader<sup>1</sup>, M. Buchhaupt<sup>1</sup>

<sup>1</sup>Biochemical Engineering, DECHEMA Research Institute, Frankfurt am Main, Germany

<sup>2</sup>Institute for Microbiology, ETH Zurich, Zurich, Switzerland

**Background**

There is a high need for sustainably producible chemical building blocks being applicable e.g. as monomers for novel bioplastics. The ethylmalonyl-CoA pathway (EMCP) harbors several CoA-esters such as ethylmalonyl-, methylsuccinyl- or mesaconyl-CoA whose free dicarboxylic acid derivatives potentially present promising synthons for chemical industry. The EMCP in *Methylobacterium extorquens* offers the possibility to produce these new building blocks directly from the cheap and non-food competing C-source methanol.

**Objectives**

Main objective of this work was the optimization of dicarboxylic acid production with *M. extorquens* strains expressing a thioesterase towards an industrially relevant process.

**Methods**

Suitable thioesterase enzymes were identified by *in vitro* assays and the product spectra were analyzed by *in vivo* experiments. Expression of thioesterases in different *M. extorquens* strains was increased by optimization of ribosome binding sites. To increase carbon flux into product and avoid acid reuptake we used metabolic engineering and medium optimization strategies. First high cell density fermentations were performed in a bioreactor.

**Conclusions**

Suitable thioesterases for production of different EMCP-derived dicarboxylic acids were identified and their expression levels in *M. extorquens* were optimized. Productivities of different strains were compared and increased by different metabolic engineering and medium optimization strategies. In summary, we present the biotechnological production of unconventional dicarboxylic acids from methanol with high efficiency.

## **PLANT SECONDARY METABOLITE PRODUCTION IN SACCHAROMYCES CEREVISIAE**

L. Blank<sup>1</sup>, K. Walter<sup>1</sup>, E. Czarnotta<sup>1</sup>, B. Ebert<sup>1</sup>

<sup>1</sup>Aachen Biology and Biotechnology - ABBt, Institute of Applied Microbiology - iAMB, Aachen, Germany

### **Background**

The diversity of metabolites of plants with an estimated 200,000 different compounds is unrivaled by any other group of organisms. Many of these metabolites have special features, ranging from scents to antimicrobial agents. The limited availability of secondary metabolites often hinders their exploitation. This can be overcome by implementing synthesis pathways into the yeast *Saccharomyces cerevisiae* that has an excellent track record in white biotechnology.

### **Objectives**

We constructed and characterized *S. cerevisiae* microbial cell factories producing triterpenoids.

### **Methods**

Advanced metabolic engineering including compartment engineering was employed to redistribute carbon flux through the mevalonate pathway and squalene synthesis towards triterpenoids. The product performance of the engineered strains was investigated by bioprocess engineering, while advanced analytics delivered targets for the next round of strain improvement.

### **Conclusions**

*S. cerevisiae* was engineered for triterpenoid production. In fermentations considerable titers of these valuable secondary plant metabolites could be produced. The results will be presented in the context of the required molecular tools and novel engineering targets.

<sup>2</sup>ACIB GmbH, Institute of Molecular Biotechnology, Graz, Austria

<sup>3</sup>BASF SE, Advanced Materials & Systems Research - Biopolymers, Ludwigshafen, Germany

<sup>4</sup>University of Natural Resources and Life Sciences Vienna, Institute for Environmental Biotechnology, Tulln, Austria

### **Background**

In nature microbes are equipped with enzymes and helper proteins to modify and degrade naturally occurring polymers including polyesters. Due to huge environmental problems, the development of efficient polyester recycling strategies and improvement of biodegradable polyesters that show required material properties is necessary. Learning strategies from microbes enables us to fight against these ecological problems and process polymers efficiently.

### **Objectives**

Here, strategies based on novel microbial enzymes for tailor-made polyester modification and degradation are presented. Mimicking nature, enzymes have been genetically equipped with polymer binding modules [1]. Moreover, mechanistic insights into the enzymatic hydrolysis of synthetic polyesters like polyethylene terephthalate and the compostable synthetic polyester poly(butylene adipate-co-butylene terephthalate) by cutinases and novel “anaerobic” esterases are given.

### **Methods**

The enzymatic hydrolysis of polyesters by cutinases e.g. from *Thermobifida cellulosilytica* (Thc\_Cut1) and novel anaerobic esterases from different *Clostridium* spp. was investigated via HPLC-MS. Additionally, fusion proteins of Thc\_Cut1 and binding modules of polyhydroxyalkanoate depolymerases and combination with hydrophobins from *Trichoderma* spp. [2] were investigated.

### **Conclusions**

Novel enzymes isolated from anaerobic microorganisms were demonstrated to degrade synthetic polyesters. The adsorption as well as the activity of microbial

polyesterases was increased when fused to different binding modules or when hydrophobins were applied when compared to the native enzyme.

**Microbial symbioses with marine animals**

**How to eat without a mouth or gut: symbioses between chemosynthetic bacteria and gutless marine worms**

N. Dubilier<sup>1</sup>

<sup>1</sup>*Symbiosis Department, Max Planck Institute for Marine Microbiology, Bremen, Germany*

Marine worms without a mouth or gut were first discovered over 35 years ago in coral reef sediments, but the mystery of how they gain their nutrition was not solved until large communities of gutless invertebrates were discovered in 1977 at hydrothermal vents in the deep sea. We now know that these animals gain their nutrition from chemosynthetic bacteria that fix carbon dioxide into organic compounds, as in photosynthesis, but using reduced compounds such as sulfide or methane as energy sources instead of sunlight. Chemosynthetic symbioses occur worldwide and have evolved multiple times from numerous bacterial lineages and at least 9 animal groups (Dubilier et al. 2008. *Nature Rev Microbiol*). In my talk, I will present an overview of the research in my lab on these symbioses and describe how new tools that range from in situ instruments for measuring environmental parameters to lab-based methods such as 'omics' and single cell imaging, provide the opportunity to understand symbiotic associations in their environmental and ecological context.

**Food biotechnology**

**The transcriptome landscape of *Lactococcus lactis*: regulatory RNAs uncovered**

J. Kok<sup>1</sup>

<sup>1</sup>*Molecular Genetics, Top Institute Food and Nutrition (TIFN),  
University of Groningen, Groningen, Netherlands*

The lactic acid bacterium *Lactococcus lactis* is of high importance in biotechnology, specifically in the dairy industry. It is used in starter cultures world-wide for the production of safe and nutritious milk fermentation products. Rapid acidification of milk through lactose utilization and proteolytic activity are key parameters in determining product quality. The large-scale industrial processes in which these bacteria are employed put them under a variety of intrinsic and extrinsic (technological) stresses. Consequently, stress response systems in *L. lactis* have been extensively studied, as have industrially important global transcriptional regulators of carbon and nitrogen metabolism.

It is becoming increasingly clear that, in addition to protein regulators, small non-coding RNAs play important regulatory roles in bacteria. Recent developments in next-generation RNA sequencing and in bioinformatics have revolutionized transcriptome analyses. As a result, novel non-coding RNAs have been discovered in many micro-organisms and subsequent studies have uncovered several regulatory mechanisms that operate at the level of RNA.

The presence and roles of non-coding RNAs with regulatory functions have not yet been assessed in *L. lactis*. Because of their presumed importance, we set out to identify novel RNA elements, such as small regulatory RNAs, antisense RNAs and sORFs, by growing the organism under various (stressful) conditions. Using differential RNA sequencing, a transcriptome landscape of *L. lactis* was obtained that was automatically mined using TSSer and verified and refined manually. Thus, we identified hundreds of novel RNA species. Experimental validation was performed for a selection of these potential RNA regulators. The role of one non-coding RNA located in the 3'UTR of the gene for the regulator of e.g. the *arc*-operon in *L. lactis*, ArgR, will be further detailed.

## FEMS-2815

### Food biotechnology

#### Understanding the mechanisms of yeast adaptation to wine fermentations

A. Querol<sup>1</sup>, R. Perez-Torrado<sup>1</sup>, E. Barrio<sup>2</sup>

<sup>1</sup>Food Biotechnology,

Instituto de Agroquímica y Tecnología de los Alimentos IATA-CSIC, Valencia, Spain

<sup>2</sup>Food Biotechnology,

Instituto de Agroquímica y Tecnología de los Alimentos IATA-CSIC and Departament de Genética Universitat de Valencia Valencia Spain., Valencia, Spain

The wine fermentation is a complex process produced as a result of the activities of a succession of microorganisms. Although *S. cerevisiae* is the most frequent species in wines, and the subject of most studies, *S. bayanus* var. *uvareum* and natural hybrids between *Saccharomyces* species such as *S. cerevisiae* x *S. kudriavzevii* and *S. cerevisiae* x *S. bayanus* var. *uvareum* are also involved in wine fermentations and can be preponderant in certain wine regions. Studies performed in our laboratory, showed that strains of non-conventional *Saccharomyces* species, such as *S. bayanus* var. *uvareum* and *S. kudriavzevii*, exhibit physiological properties of potential interest in enology because they can respond to the new demands of the wine industry, such as their ability to ferment at low temperatures, their increased **production of glycerol**, their lower ethanol yield (1, 2, 3). The main objective of this work is to decipher the molecular mechanisms responsables of the overproduction of glycerol in *S. kudriavzevii*, *S. bayanus* var. *uvareum* and natural strains of *S. cerevisiae* (4, 5), as well as the molecular basis involved in the cold adaptation of *S. kudriavzevii* strains (6).

<sup>1</sup>Max F. Perutz Laboratories, University of Vienna, Vienna, Austria

**Background**

The RNA chaperone Hfq has been recognized as the principle post-transcriptional regulator of carbon catabolite repression (CCR) in the opportunistic human pathogen *P. aeruginosa* (PAO1). Hfq was shown to act as a translational repressor that prevents ribosome loading through binding to A-rich sequences within the ribosome binding site of mRNAs encoding catabolic enzymes. Furthermore, the non-coding CrcZ RNA was shown to bind to and to sequester Hfq, which in turn abrogates Hfq-mediated translational repression.

**Objectives**

To study the role of *P. aeruginosa* Hfq and of the regulatory RNA CrcZ in anoxic biofilm formation and antibiotic susceptibility.

**Methods**

Biochemical and genetic methods as well as next generation sequencing were employed to address the impact of Hfq and CrcZ on anoxic biofilm formation and antibiotic susceptibility of *P. aeruginosa*.

**Conclusions**

Comparative transcriptome studies identified CrcZ as being up-regulated in anoxic biofilms of PA14 grown under conditions that mimic growth in the cystic fibrosis lung. We show that CrcZ up-regulation suppresses biofilm formation, which most likely results from sequestration of Hfq. Moreover, RNA-seq analyses revealed functions that account for decreased biofilm formation upon CrcZ up-regulation. In addition, we show that CrcZ affects the susceptibility of PA14 towards several antibiotics, which in turn can explain the differential susceptibility of *P. aeruginosa* to certain antibiotics during planktonic and biofilm growth, respectively.

**Small regulatory RNAs in type I toxin-antitoxin systems**

S. Brantl<sup>1</sup>, N. Jahn<sup>1</sup>, C. Meißner<sup>1</sup>, C. Maiwald<sup>1</sup>, C. Ring<sup>1</sup>

<sup>1</sup>Lehrstuhl für Genetik AG Bakteriengenetik, Friedrich-Schiller-Universität Jena, Jena, Germany

Toxin-antitoxin (TA) systems are pairs of adjacent genes in which a stable toxic peptide is neutralized by an unstable antitoxin. A broad variety of type I TA systems are known in which the antitoxin is a small RNA that is convergently transcribed to the toxin mRNA, and inhibition occurs by RNA/RNA binding. The antitoxin either inhibits translation or facilitates degradation of the toxin mRNA. We investigate two type I systems from the *B. subtilis* chromosome, *bsrG*/SR4 and *bsrE*/SR5. The toxins are small hydrophobic peptides, and toxin and antitoxin genes overlap at their 3' ends by ≈120 nt. Whereas BsrG (38 aa) causes cell lysis in the absence of its antitoxin SR4, BsrE (30 aa) is only toxic upon overexpression. The antitoxins SR4 and SR5 promote toxin mRNA degradation by recruiting RNase III. In contrast to SR5, SR4 has a second function: it induces structural changes around the *bsrG* SD sequence, thus further obstructing ribosome binding which results in translational inhibition.

Secondary structures of toxin RNA, antitoxin and their complexes were mapped, apparent binding rate constants ( $k_{app}$ ) of wild-type and mutated toxin/antitoxin pairs determined, and the results corroborated by *in vivo* experiments. The binding pathways of toxin mRNA and antitoxin were elucidated by employing time-course experiments. In both cases, binding initiates between the antitoxin terminator-loop and loop 4 of toxin mRNA.

RNases involved in the degradation of toxin mRNAs and antitoxins were identified. RNase R plays the major role in *bsrG*/SR4, whereas RNase J1 is a crucial player in *bsrE*/SR5. Antitoxin-induced RNase III cleavage sites in *bsrG* and *bsrE* mRNAs were mapped.

Whereas *bsrG*/SR4 is the first temperature-sensitive TA system, factors affecting *bsrE*/SR4 expression have still to be identified.

**New players in the field of small regulatory RNAs**

E. Masse<sup>1</sup>, D. Lalaouna<sup>1</sup>, M.C. Carrier<sup>1</sup>

<sup>1</sup>Biochemistry, University of Sherbrooke, Sherbrooke, Canada

Bacterial small RNAs (sRNAs) are crucial regulators of cellular functions by modulating gene expression in response to various environmental changes. Many bacterial species were shown to express hundreds of sRNAs. These sRNAs regulate target mRNAs by direct base-pairing to positively or negatively affect their translation and stability. In *E. coli* and other Enterobacteriaceae, the sRNA RyhB regulates iron homeostasis. Under iron-rich conditions, the transcriptional repressor Fur blocks *ryhB* transcription. During conditions of iron starvation however, Fur becomes inactive and relieves repression of *ryhB*. Under these conditions, RyhB directly regulates approximately 20 different mRNAs encoding iron-using proteins. By binding to those mRNAs, RyhB shuts down translation and stimulate their rapid degradation through the action of the endoribonuclease E (RNase E). RyhB contributes actively to increase the levels of free intracellular Fe<sup>2+</sup> (iron sparing) under conditions of iron starvation by reducing the expression of iron-using proteins and by stimulating siderophore synthesis. Surprisingly, although we have used microarrays to successfully determine the effect of RyhB on the transcriptome of *E. coli*, this approach was insufficient to determine the regulation of undetected but important mRNAs. Thus sRNAs can significantly modulate many target mRNAs without interfering with their levels, which unfortunately prevents target detection by classical techniques. To address this challenge, we developed a method based on affinity purification and RNA sequencing, which could identify any RNA molecule interacting with sRNAs, regardless of the regulation. Thus, we used sRNAs tagged with the bacteriophage MS2 RNA stemloops, which are bound with high specificity by the MS2 coat protein. We then analysed all bound target RNAs by RNA sequencing. We will present new targets that suggest an unexpected but important mechanism for bacterial cells.

**Regulatory RNAs in the pathogenic Epsilonproteobacteria, *Helicobacter pylori* and *Campylobacter jejuni***

C.M. Sharma<sup>1</sup>

<sup>1</sup>Research Center for Infectious Diseases (ZINF), University of Würzburg, Würzburg, Germany

Genome sequencing revealed the potential proteins and a high genetic diversity of *Helicobacter pylori*, the causative agent of gastritis and gastric cancer, and the related, emerging food-borne pathogen *Campylobacter jejuni*. So far, little is known about post-transcriptional regulation in these pathogenic Epsilonproteobacteria. However, based on a differential RNA-sequencing approach (dRNA-seq), we had defined a genome-wide map of transcriptional start sites (TSS) and identified >60 small RNAs (sRNAs) in *H. pylori*. To understand how transcriptome differences could contribute to phenotypic differences among strains, we applied a comparative dRNA-seq approach to multiple *C. jejuni* strains. Our study revealed that the majority of TSS is conserved among strains, but we also observed strain-specific promoter usage and sRNA repertoires, which could contribute to strain-specific gene regulation. Based on our transcriptome datasets, we are now using *Helicobacter* and *Campylobacter* as new model organisms for riboregulation in virulent bacteria and bacteria without the RNA chaperone Hfq. We are functionally characterizing abundant sRNAs and are especially interested in their roles and underlying molecular mechanisms in stress response and virulence control. For example, we could show that the highly abundant and conserved sRNA, RepG, from *Helicobacter* directly base-pairs with a homopolymeric G-repeat in the mRNA leader of the chemotaxis receptor TlpB and that length variation of this G-repeat determines the outcome (repression or activation) of RepG-mediated post-transcriptional regulation. More recently, we have identified additional RepG targets, including genes involved in LPS biosynthesis or oxidative stress response, and a potential functional RepG homolog in *C. jejuni*. The example of RepG shows that identifying and studying sRNAs in bacteria without Hfq can reveal new twists in RNA-mediated regulation and will provide new insights into regulatory mechanisms and virulence control of bacterial pathogens.

*<sup>1</sup>ITQB, ITQB Universidade Nova de Lisboa, Oeiras, Portugal*

The dissimilation of sulfur compounds is likely to have been one of the first energy metabolisms on the early Earth [1]. However, many questions remain about how sulfur-metabolizing organisms obtain energy for growth from reducing, oxidizing or disproportionating sulfur compounds. In the case of sulfate reduction, the terminal reductases involved (APS reductase, AprAB, and dissimilatory sulfite reductase, DsrAB) have long been identified, but how these two reactions are coupled to energy conservation is still not clear. DsrAB, in particular, is a key enzyme in dissimilatory sulfur metabolism, being present not only sulfate/thiosulfate/sulfite reducing organisms, but also in sulfur-oxidizers and sulfur disproportionators.

Our lab has studied several of the key proteins involved in sulfate reduction, including AprAB, DsrAB and two respiratory membrane complexes specific to sulfur-metabolizing organisms, QmoABC and DsrMKJOP, which are involved in the electron transfer pathways with AprAB and DsrAB [2]. These complexes hint at the possibility of menaquinone involvement and chemiosmotic energy conservation, during sulfate reduction. In addition, a genomic analysis of energy metabolism genes in sulfate reducers suggested that the recently recognized process of electron bifurcation may also be involved [3], and that there are conspicuous links between sulfate reducers and methanogenic organisms [1].

In this talk I will present an overview of the role of these proteins in sulfate reduction, with a special focus on the function of the small protein DsrC as a physiological partner of DsrAB and the DsrMKJOP complex [4].

**New Insights into the Metabolism of Nitrate-driven Anaerobic Oxidation of Methane**

C.U. Welte<sup>1</sup>

<sup>1</sup>*Department of Microbiology, Radboud University, Nijmegen, Netherlands*

Methane oxidation is an important process to prevent emission of the greenhouse gas methane and further exacerbating of climate forcing. Both aerobic and anaerobic microorganisms have been reported to catalyze methane oxidation with only few substrates as electron acceptors. New microorganisms were discovered that coupled the oxidation of methane to nitrate or nitrite reduction [1-3].

Here, we investigated such an enrichment culture on physiological, biochemical, transcriptomic and genomic level to establish a metabolic model of nitrate-driven anaerobic oxidation of methane (nitrate-AOM). Nitrate-AOM is catalyzed by an archaeon closely related to methanogens. Methane may be activated by methyl-CoM reductase and subsequently undergo full oxidation to carbon dioxide via reverse methanogenesis. All enzymes of this pathway were present and expressed in the investigated culture. The genome of the archaeal culture encoded a variety of proteins involved in a membrane-bound electron transport chain similar to those found in *Methanosarcina* species. Nitrate reduction seems to be located in the extracellular space and may be catalyzed by Nxr- or Nar-like protein complexes. The enrichment culture produced mainly nitrite but also some ammonium during nitrate reduction, presumably by the action of an extracellular Nrf enzyme. One of the key questions is how electrons from cytoplasmic reverse methanogenesis reach the nitrate reduction enzymes in the extracellular space. We will present a tentative model, based on genome and transcriptome studies, how electrons from reverse methanogenesis are transported to the nitrate and nitrite reductases, thereby suggesting how central energy metabolism of nitrate-driven anaerobic oxidation of methane could work.

**Microbial life under extreme energy limitations: how to make a living by producing acetate from hydrogen and carbon dioxide**

V. Müller<sup>1</sup>

<sup>1</sup>*Molecular Microbiology & Bioenergetics, Johann Wolfgang Goethe University, Frankfurt am Main, Germany*

Acetogens constitute an important limb in anaerobic food webs. Synthesis of acetate from carbon dioxide and molecular hydrogen *via* the Wood-Ljungdahl pathway is thermodynamically at the edge of life since it allows or the synthesis of only a fraction of an ATP. How the pathway is coupled to the net synthesis of ATP has been an enigma for a long time, but recently, new insights have been obtained using the anaerobic, acetogenic bacterium *Acetobacterium woodii* as a model system (1,2). The energy conserving module comprises of a Na<sup>+</sup> translocating ferredoxin-NAD oxidoreductase (Rnf complex) (3) and an unusual Na<sup>+</sup>-F<sub>1</sub>F<sub>0</sub> ATP synthase (4). Endergonic reduction of ferredoxin with H<sub>2</sub> as electron donor is achieved by energy coupling *via* electron bifurcation (5). Reduction of CO<sub>2</sub> to formate with NADH would be highly endergonic and this energetic barrier is overcome by a novel hydrogen-dependent CO<sub>2</sub> reductase (6).

Under anaerobic conditions many microorganisms are able to utilize insoluble metal species during respiration. In Gram-negative organisms this requires electrons that accumulate in the menaquinol pool to be transported across the periplasm, through the outer membrane and ultimately transferred to an extracellular electron acceptor. One of the best-studied organisms capable of metal respiration is the facultative anaerobe *Shewanella oneidensis*, which produces a range of multiheme cytochromes that facilitate electron transfer to extracellular minerals.

During mineral respiration *S. oneidensis* utilizes a porin-cytochrome complex to shuttle electrons from the periplasm across the outer membrane. This complex is comprised of a periplasmic decaheme cytochrome (MtrA), a 28-strand porin (MtrB) and an outer membrane decaheme cytochrome (MtrC) that forms the interface between the cell and mineral surfaces. During anaerobic respiration *S. oneidensis* also secretes trace amounts of flavin mononucleotide (FMN) and this has been linked to effective reduction of insoluble metals. FMN was originally proposed to function as a soluble electron shuttle mediating electron exchange between extracellular cytochromes and the mineral surface, however we have recently shown that FMN binds tightly to the extracellular MtrC, becoming a eleventh cofactor under anaerobic conditions. These findings, coupled with new structural and kinetic information have allowed us to reconsider how the cytochromes of *Shewanella* are used during dissimilatory metal reduction.

**Cell-cell communication / Quorum sensing: basic aspects**

**Unravelling autoinducing peptide biosynthesis and recognition in staphylococci**

P. Williams<sup>1</sup>

<sup>1</sup>*Life Sciences, University of Nottingham, Nottingham, United Kingdom*

The *agr* quorum sensing (QS) system plays a pivotal role in the co-ordination of virulence in *Staphylococcus aureus* and other closely related Gram-positive bacteria. The *agr* locus consists of two divergent transcriptional units controlled by the *agrP2* and *agrP3* promoters. The *agrP2* operon consists of four genes, *agrBDCA*. AgrB processes the pre-propeptide AgrD to generate a macrocyclic auto-inducing peptide (AIP). This is exported from the cell and subsequently recognized by AgrC, a transmembrane receptor kinase that activates the response regulator, AgrA. This drives expression of the *agrP2* operon completing the autoinduction loop as well as the *agrP3* operon which codes for both delta-toxin and a regulatory RNA, RNAIII, the primary effector of the *agr* response. The *agr* locus has undergone evolutionary divergence such that the AIPs of four different *S. aureus agr* groups self-activate but cross-inhibit. Consequently to retain functionality, any changes in the AIP-encoding gene (*agrD*) that results in modification of the AIP structure must be accompanied by corresponding changes in the AgrC receptor. To better understand the biosynthesis and recognition of staphylococcal AIPs we have exploited both *in vivo* and *in vitro* chemical biology approaches to gain new insights into the function of AgrB and the structural features of the AIPs and AgrC that determine activation or inhibition of the sensor kinase. This work is of particular relevance to the design of *agr* inhibitors as antivirulence agents for the prevention and treatment of staphylococcal infections.

**Interspecies and interkingdom signaling in plant associated bacteria**

V. Venturi<sup>1</sup>

<sup>1</sup>*Bacteriology, ICGEB, Trieste, Italy*

Just like what occurs in humans, plants have been recently recognized as meta-organisms possessing a distinct microbiome which has close relationship with their associated microorganisms. The plant microbiome presents an additional reservoir of genes that the plant can have access to when needed. Plant health is thought to heavily depend also on its microbiome and plants most probably intimately affect bacterial gene expression via a communication highway of signals produced by bacteria and plants. These complex highways will become clearer through the detection of signal molecules and identifying the effects on gene expression of microbial and plant exudates. Although plant microbiome composition is now being well studied, there is hardly any information on these signals.

Interspecies and interkingdom signaling, is now a fast developing field of research; we are using plant associated bacteria to investigate these types of communication. We have identified a new sub-family of bacterial LuxR proteins which is widely present in plant associated proteobacteria which binds and consequently responds to plant signals. In addition we are using a plant disease as model of interspecies bacterial interactions which also highlights the role of these interactions in bacterial plant pathogenicity. Understanding these types of communication between microbiomes and plants are a step in the right direction for disease management.

## FEMS-0615

### Cell-cell communication / Quorum sensing: basic aspects

#### The DSF family of bacterial cell-cell signal molecules

M. Dow<sup>1</sup>

<sup>1</sup>*School of Microbiology, University College Cork, Cork, Ireland*

The Diffusible Signal Factor (DSF) family of cell-to-cell signalling molecules comprises *cis*-2-unsaturated fatty acids that differ in their chain length and branching. DSF signalling was first described in the plant pathogen *Xanthomonas campestris* (Xcc) where the signal was identified as *cis*-11-methyl-dodecenoic acid. The synthesis and perception of the DSF signal in Xcc require products of the *rpf* gene cluster (for regulation of pathogenicity factors). The synthesis of DSF is dependent on RpfF, whereas the RpfC/RpfG two-component system is implicated in DSF perception and signal transduction. RpfC is a complex hybrid sensor kinase whereas the RpfG regulator has a CheY-like receiver domain attached to an HD-GYP domain, which acts to degrade the second messenger cyclic di-GMP, leading to regulation of the expression of virulence factors. Recent work has described a second receptor for DSF in Xcc; the RpfS sensor kinase binds DSF through an N-terminal PAS domain to control factors involved in the epiphytic phase of the disease cycle. Although DSF signalling has now been described in several *Xanthomonas* species and the related genera *Xylella* and *Stenotrophomonas*, it is not restricted to xanthomonads. DSF family signals are produced by the human pathogens *Burkholderia cenocepacia* and *Pseudomonas aeruginosa* where they act to regulate virulence, biofilm formation and antibiotic tolerance. Two sensors for DSF family signals have been described in *B. cenocepacia*: a membrane-associated histidine kinase unrelated to RpfC and a soluble PAS-GGDEF-EAL domain protein that couples DSF sensing to cyclic di-GMP turnover. In addition to intraspecies signalling, DSF family signals have been implicated in interspecies signalling that modulates bacterial behavior to include antibiotic tolerance. An understanding of these diverse signalling mechanisms could suggest strategies for interference, with consequences for disease control.

**Cell-cell communication / Quorum sensing: basic aspects**

**Quorum sensign in rhizobia: getting attached to their roots**

J.A. Downie<sup>1</sup>, M. Frederix<sup>1</sup>, A. Edwards<sup>1</sup>, A. Swiderska<sup>1</sup>, A. Stanger<sup>1</sup>,  
R. Karunakaran<sup>1</sup>, P.S. Poole<sup>1</sup>

<sup>1</sup>Molecular Microbiology, John Innes Centre, Norwich, United Kingdom

**Background:** Most rhizobia have N-acyl-homoserine (AHL)-based quorum sensing regulatory systems. These influence phenotypes such as plasmid transfer, exopolysaccharide synthesis and processing, biofilm formation, motility and root attachment.

**Objectives:** In *Rhizobium leguminosarum* bv. *viciae*, which forms nitrogen-fixing nodules on peas and vetch, quorum-sensing regulation plays an important role in competitiveness for nodule infection. Our aim was to identify the key genes for this and their regulation.

**Methods:** We identified a small protein (CinS) that is co-expressed in a population-density-dependent manner with the AHL synthase CinI. CinS binds to the repressor PraR, thereby relieving repression of several genes including LuxR-type quorum-sensing regulators. Mutation of *praR* enhanced biofilm formation *in vitro* and on legume roots; this was correlated with enhanced infect infection of pea nodules in competition with the wild-type. Analysis of gene expression by microarrays and promoter fusions revealed that PraR represses its own transcription and the expression of several genes including those encoding secreted proteins (including the adhesins RapA2, RapB and RapC, a cadherin and the glycanase PlyB). Single mutations in *rapA2*, *rapB*, *rapC*, *plyB*, the cadherin or *rosR* did not affect the enhanced root attachment or nodule competitiveness of the *praR* mutant. However combinations of mutations in *rapA*, *rapB* and *rapC* abolished the enhanced attachment and nodule competitiveness.

**Conclusions:** Relief of PraR-mediated repression via quorum-sensing regulation determines a lifestyle switch allowing the expression of genes that are important for biofilm formation on roots and consequently enhances infection of legume roots and formation of nitrogen-fixing nodules.

We thank our colleagues for help and discussion. This research was supported by the BBSRC (BB/E017045/1) and MF was supported in part by a Marie-Curie short term EST fellowship (019727).

**Jorgen Lehmann and Gerhard Domagk event on *Mycobacterium tuberculosis*: current concepts of immunity in tuberculosis and their relevance for vaccine development**

**Towards new TB vaccines - what are the challenges?**

H.M. Dockrell<sup>1</sup>

<sup>1</sup>*Department of Immunology and Infection,  
London School of Hygiene and Tropical Medicine, London, United Kingdom*

To control the global threat from tuberculosis, we urgently need new TB vaccines that induce effective protection, as well as new drug regimens and diagnostic tools. However there are significant challenges. A new TB vaccine might replace the current BCG vaccine at birth, or be given as a boosting vaccine following BCG (or a BCG replacement vaccine) to infants or young adolescents. A post exposure vaccine could be given to older adolescents or adults. In addition, a therapeutic vaccine could be given to those with clinical disease to accelerate bacterial clearance. These vaccines could include improved BCG vaccines, safe live mycobacteria, antigens delivered by viral vectors, and proteins delivered with adjuvant. Vaccines could be injected or delivered by the mucosal route. There is a vaccine development pipeline with ongoing international efforts to coordinate and facilitate the development and testing of the most promising candidates. These efforts would be accelerated if we had biomarkers or protective biosignatures that predicted the protective efficacy of a new vaccine. Although there is increasing investment in non-human primate models, at present we also do not have animal models that reliably predict protection in man, so the main challenge is how to prioritise development of the best candidate vaccines. Although some measures of immunity have proved disappointing, there are promising developments exploiting gene expression signatures and novel mycobacterial growth inhibition assays. Identifying protective biosignatures, which may differ for different types of vaccines, would greatly facilitate the prioritisation of new TB vaccine candidates for further development. It would also be useful if we could understand better why the existing BCG vaccine induces such variable protection, to ensure that any new TB vaccine will work irrespective of location.

**Steps ahead in the Development of New Vaccines Against Tuberculosis, searching for new attenuated vaccines**

C. Martin<sup>1</sup>

<sup>1</sup>Microbiology, University of Zaragoza, Zaragoza, Spain

Steps ahead in the development of new vaccines against Tuberculosis, searching for the new attenuated vaccines

Carlos Martin

University of Zaragoza  
<http://genmico.unizar.es/>

One of the major challenges in the field of TB vaccines is the lack of a correlation of protection what necessary for efficacy evaluation of new vaccines in clinical trials in endemic countries. Live attenuated vaccine candidate MTBVAC is an attenuated *Mycobacterium tuberculosis* (MTB) genetically engineered to fulfil the Geneva consensus requirements to enter human clinical trials. We selected a MTB clinical isolate belonging to Euro-American lineage to generate two independent deletions without antibiotic-resistance markers. One is the *phoP*, essential for virulence in MTB where it controls expression of approximately 2% of the genes, including those for the ESX-1 secretion apparatus, a major virulence determinant and the secretion of the immunodominant Ag85 complex. Deletion in *phoP* gene lead to compromised production of pathogen-specific cell wall components and attenuation both *ex vivo* and *in vivo*. Deletion in *fadD26*, inactivate phthiocerol dimycocerosates (DIM) operon which, codes for the production of one of the major MTB virulence factors.

MTBVAC exhibits safety and biodistribution profiles similar to BCG and confers superior protection in preclinical studies. A major difference between MTBVAC and BCG, which is derived from the cattle pathogen *M. bovis*, is that BCG has many deletions in its genome when compared to MTB, and during the attenuation process BCG had lost over a hundred additional genes from its genome including immunodominant antigens. After more than 15 years of preclinical development MTBVAC is the first live attenuated vaccine to enter clinical evaluation in Lausanne

(Switzerland) with Prof Spertini as Principal Investigator and sponsored by Biofabri and TBVI (ClinicalTrials.gov: NCT02013245).

**MYCOBACTERIUM MARINUM CAN CROSS THE BLOOD-BRAIN BARRIER VIA DIFFERENT MIGRATION ROUTES**

*L.M. van Leeuwen<sup>1</sup>, A.M. van Furth<sup>2</sup>, W. Bitter<sup>1</sup>, M. van der Kuip<sup>2</sup>, A.M. van der Sar<sup>1</sup>*

*<sup>1</sup>Medical Microbiology and Infection control, VU University Medical Center, Amsterdam, Netherlands*

*<sup>2</sup>Pediatric Infectious Disease and Immunology, VU University Medical Center, Amsterdam, Netherlands*

**Background**

Tuberculous meningitis (TBM) is a major disease burden in children in TB endemic countries.

**Objectives**

We use our zebrafish – *Mycobacterium marinum* infection model for TBM to study early granuloma formation in brain and meninges of zebrafish embryos.

**Methods**

We dissected the migration mechanism employed by *M. marinum* to cross the blood-brain barrier (BBB) and cause infection of the central nervous system. To study the role of macrophages in this process, we depleted the macrophage pool in zebrafish embryos with pu.1 morpholinos and clodronate filled liposomes. Embryos lacking phagocytic cells showed an increased overall infection rate and a higher bacterial load in the head at 5 days post infection in comparison to the control group. Detailed analysis showed that in the presence of macrophages, *M. marinum* leaves the bloodstream and forms early granulomas consisting of mycobacteria and L-plastin positive phagocytes in brain tissue. Virtually all *M. marinum* inside and outside the blood vessels were present in phagocytic cells, suggesting that mycobacteria use macrophages as a Trojan horse to cross the BBB. As expected, we did not observe granuloma structures after macrophage depletion. However, we still found extravasated mycobacteria in the brain parenchyma. Most of these mycobacteria were found in close vicinity of blood vessels, following the blood vessel shape in a longitudinal manner.

**Conclusions**

We observed that *M. marinum* preferably use macrophages as Trojan Horses to cross the BBB. However, in the absence of macrophages *M. marinum* can adept and seems capable of using additional migration routes.

## **THE ROLE OF A TYPE VII SECRETION CHAPERONE IN THE SPECIFIC SUBSTRATE RECOGNITION IN PATHOGENIC MYCOBACTERIA**

T. Phan<sup>1</sup>

<sup>1</sup>*Melecular Microbiology, VU University, Amsterdam, Netherlands*

### **Background**

Type VII secretion (T7S) is employed by mycobacteria, including the important pathogen *Mycobacterium tuberculosis*, to export protein effectors across their highly unusual cell envelope. *M. tuberculosis* contains five paralogous T7S systems, ESX-1 to ESX-5, each having its own role in viability and/or virulence. The mycobacteria-specific PE/PPE proteins are one group of proteins that are secreted via these secretion systems, of which at least some are secreted as heterodimers. We have previously shown that the cytosolic chaperone EspG specifically interacts with cognate PE/PPE dimers and is required for their successful secretion.

### **Objectives**

Our aim is to understand the determinant factors for substrate-specific binding of EspG to T7S substrates.

### **Methods**

The crystal structure of ESX-5 chaperone EspG<sub>5</sub> with the ESX-5 substrate pair PE25/PPE41 was determined and important residues for chaperone-binding of several PPE proteins were mutated. Additionally, EspG-binding domains of ESX-1 and ESX-5 substrates were exchanged.

### **Conclusions**

The structure revealed that EspG<sub>5</sub> interacts with the elongated end of PPE41, a region containing several hydrophobic residues that are conserved in PPE substrates of different secretion systems. Mutating these residues of multiple ESX-5 PPE substrates and an ESX-1 dependent PPE protein abolished the interaction with the cognate chaperone and blocked their secretion by *Mycobacterium marinum*. Subsequently, exchanging the complete EspG-binding domain between an ESX-1 and ESX-5 PPE protein altered chaperone-binding specificity. The effect of system-specific chaperone-binding on rerouting of T7S substrates is currently tested. In

summary, we have elucidated the molecular determinants for EspG-specific binding to PPE substrates and the key role of chaperone-binding in secretion.

<sup>1</sup>*Leprosy Research Center, National Institute of Infectious Diseases, Tokyo, Japan*

**Background**

*Mycobacterium leprae* (*M. leprae*), the causative agent of leprosy, parasitizes within lipid droplets stored in enlarged phagosome of histiocytes, which is thought to be important nutrient source and sheltering for the bacillus. However, the mechanisms by which *M. leprae* triggers lipid accumulation within phagosomes remain unclear.

**Objectives**

To elucidate the mechanism underlying *M. leprae*-induced lipid accumulation in macrophages.

**Methods**

Real-time PCR, western blotting, histochemical staining and DNA microarray were employed to analyze human premonocytic THP-1 cells infected with *M. leprae* as well as skin biopsies and smears of leprosy patients.

**Conclusions**

Live *M. leprae*, but not heat-killed *M. leprae*, specifically induced adipose differentiation-related protein (ADRP) and perilipin, which are essential regulators for lipid accumulation, in THP-1 cells. However, live *M. leprae* suppressed and inactivated hormone sensitive lipase (HSL). Clofazimine, one of the drugs for treating leprosy, devastated the *M. leprae*-induced lipid-rich intracellular environment by modulating the expression of ADRP and HSL, and by activating the innate immune response in host macrophages. Staining of skin biopsies and smears confirmed the above results. DNA microarray analysis revealed that live *M. leprae* modulated gene expressions important for lipid accumulation, as well as their common transcriptional factors, *i.e.* peroxisome proliferator-activated receptor (PPAR) $\delta$  and PPAR $\gamma$ . The antagonists of PPAR $\delta$  and PPAR $\gamma$  abolished the effect of *M. leprae* to modulate such gene expressions and lipid accumulation in macrophages. These results indicate that live *M. leprae* creates lipid-rich intracellular environment by modulating gene expressions of host macrophages through PPAR $\delta$  and PPAR $\gamma$  signaling.

### Imaging of macromolecular structures

#### Structure and evolution of rotary motors

M. Beeby<sup>1</sup>, B. Chaban<sup>1</sup>, A. Wilson<sup>1</sup>, D. Hendrixson<sup>2</sup>

<sup>1</sup>Life Sciences, Imperial College London, London, United Kingdom

<sup>2</sup>Medical Center, UT Southwestern, Houston, USA

Microbes propel themselves in beneficial directions using cell wall-embedded rotary motors that spin helical propellers. Bacteria swim using bacterial flagellar motors, large nanomachines composed of hundreds of proteins — from approximately twenty protein families — that harness proton-motive force to convey torque to a multi-micron flagellum, while archaea assemble "archaella" that utilize ATP hydrolyse to rotate an analogous filament. How do these function, and how did they evolve? To understand this we are using electron cryo-tomography to perform 3D in situ imaging of these motors. We have recently shown that bacterial flagellar motors are considerably more complex than the 'normal' core motor found in *Salmonella* and *E. coli*, thus shedding light on the evolutionary processes used to adapt macromolecular machinery. Why have some bacteria recruited additional proteins to a core that is already fully functional? I will describe phylogenetic and structural work to understand this question. We are currently focusing on a family of large novel structural components found in a variety of proteobacteria including the *Vibrio*, *Campylobacter*, and *Helicobacter* genera. By combining bacterial genetics, phylogenetics and electron cryo-tomography we have identified the proteins that form these large structures. Combining these results we have developed a model for the recruitment of these additional proteins, and have been able to speculate on the effect of these proteins on motor mechanics, in turn highlighting possible evolutionary driving forces behind protein recruitment. I will then describe recent work to study the analogous archaellar motor.

**Imaging of macromolecular structures**

**Cryo-EM of the Type VII secretion system in *Mycobacterium tuberculosis***

P. Peters<sup>1</sup>

<sup>1</sup>*Division of Nanoscopy, Maastricht MultiModal Molecular Imaging Institute (M4I),  
Maastricht, Netherlands*

We showed in Cell; 129:1287 that after prolonged infection in macrophages and dendritic cells, *M. tuberculosis* translocates from phago-lysosomes to the cytosol and killed the host cell a few days later, while the BCG vaccine strain failed to translocate. We found that this process was dependent on a gene in the extended RD1 region (ext-RD1). We then focused on BCG with a knock-in of the entire ext-RD1, which was recently identified by one of our former team member as a novel type VII secretion system (T7SS) (Abdallah AM et al., Nat Rev Microbiol. 2007). We found that these bacteria translocate to the cytosol of the host cell 7 days after infection. We concluded that the ESX-1 system is sufficient for translocation (Abdallah AM et al., J of Immunol. 2011 and Houben et al., Cell Microbiol. 2012).

Since my move to Maastricht University where I was invited to establish a new Institute for Nanoscopy ([www.maastrichtuniversity.nl/m4i](http://www.maastrichtuniversity.nl/m4i)) we are now using cryo-EM single-particle analysis (SPA), and cryo-EM tomography. We investigate recombinant purified proteins of individual gene products from the T7SS. In addition, we are purifying the entire intact T7SS structure using biochemical methods for 3D reconstruction. We will also generate lamellae of infected cells using cryo-FIB/SEM technology. This should lay the groundwork for the development of novel antibiotics and better vaccines. Since this FEMS meeting is next door to my new laboratory interested colleagues are welcome to contact me for a visit (Universiteitssingel 50, Room G0.201) while attending the meeting ([peter.peters@maastrichtuniversity.nl](mailto:peter.peters@maastrichtuniversity.nl)).

<sup>3</sup>Biochemistry, University of Cambridge, Houston, USA

<sup>4</sup>Pharmacology, University of Cambridge, Cambridge, United Kingdom

<sup>5</sup>Pharmacology, University of South Australia, Adelaide, Australia

Microorganisms encode several classes of transmembrane molecular pumps that can expel a wide range of chemically distinct toxic substances. These machines contribute to the capacity of the organisms to withstand harsh environments, and they help to confer resistance against clinical antimicrobial agents. In Gram-negative bacteria, the pumps comprise tripartite assemblies that actively transport drugs and other harmful compounds across the cell envelope. We describe recent structural and functional data that have provided insights into the architecture and transport mechanism of the AcrA-AcrB-TolC pump of *Escherichia coli*. This multi-drug efflux pump is powered by AcrB, a member of the resistance/nodulation/cell division (RND) family of transporters, which are energised by proton electrochemical gradients. Crystallographic data reveal how a small protein AcrZ is engaged in a concave surface in the transmembrane domain of AcrB, and we discuss how this interaction may affect the efflux activities of AcrB and other RND family members.

**FEMS-3165**

**Imaging of macromolecular structures**

**Structure and function of type 6 secretion and related assemblies**

M. Pilhofer<sup>1</sup>

<sup>1</sup>*Biology, ETH Zürich, Zürich, Switzerland*

Interactions of a bacterial cell with other bacteria, eukaryotes or archaea are crucial for symbiosis, pathogenicity, competition and defense. These bacterial cell-cell interactions are often mediated by macromolecular machines. In evolution, a phage-derived bacterial contractile structure proved to be very successful in mediating cell-cell interactions in an either contact-dependent or indirect manner. We applied electron cryotomography in an interdisciplinary approach to understand the structure and mechanism of the type VI secretion (T6S) system, arrays of metamorphosis-associated contractile structures (MACs), and other bacterial contractile assemblies. State-of-the-art sample preparation techniques recently allowed us to image bacteria engaging with a eukaryotic host.

**FEMS-2839**

**Bacterial phosphorylation networks**

**New insights into the GacS multikinase network controlling virulence in *Pseudomonas aeruginosa***

V.I. Francis<sup>1</sup>, E. Waters<sup>2</sup>, A. Kadioglu<sup>2</sup>, A.R. Brown<sup>1</sup>, S.L. Porter<sup>1</sup>

<sup>1</sup>Biosciences, University of Exeter, Exeter, United Kingdom

<sup>2</sup>Institute of Infection and Global Health, University of Liverpool, Liverpool, United Kingdom

The GacS/A two-component signalling network of *Pseudomonas aeruginosa* plays a major role in controlling virulence. This network features multiple sensor kinases that work together to decide between acute and chronic modes of infection [1,2]. Signalling by the kinase GacS favours chronic infection, while another kinase, RetS, favours acute infection by inhibiting GacS. We have been investigating how RetS interferes with GacS function and we have found that there are three distinct ways in which RetS can inhibit GacS: 1) RetS can accept phosphoryl groups from GacS-P; 2) RetS has phosphatase activity towards GacS-P; and 3) RetS prevents autophosphorylation of GacS. We can selectively disable each of these mechanisms by introducing specific point mutations into RetS and have tested the effects of these mutations in a mouse model of respiratory infection. We find that loss of either mechanism 1 or 2 dramatically decreases acute virulence, while loss of both mechanisms 1 and 2 abolishes acute virulence. RetS function *in vivo* therefore depends upon its ability to bring about the dephosphorylation of GacS-P. This study reveals an unexpected degree of complexity in the intricacy of the interactions between the sensor kinases governing the choice between different modes of virulence in this important pathogen.

## FEMS-2849

### Bacterial phosphorylation networks

#### How do you Coordinate signals from two chemosensory pathways to control one flagellar motor?

J. Armitage<sup>1</sup>

<sup>1</sup>Biochemistry, University of Oxford, Oxford, United Kingdom

The chemotaxis pathway of *E.coli* is probably the best understood sensory pathway in bacteriology. A kinase, CheA, autophosphorylates in response to a decrease in attractant, and transfers a phosphoryl to either a diffusing single domain response regulator, CheY, which when phosphorylated binds the switch protein of the flagellar motor to cause a change in rotational direction, or phosphorylates a methyl esterase controlling receptor adaptation. However, many bacterial species have more than one chemosensory pathway controlling the direction of flagellar rotation.

The photoheterotrophic bacterium *Rhodobacter sphaeroides* expresses two pathways, one localised with transmembrane receptors to large patches on the membrane and one localised with soluble chemoreceptors, and associated with the chromosomes, segregating with the chromosomes on division to ensure each daughter inherits a cluster.

*In vitro* and *in vivo* methods, including phosphotransfer, fluorescence microscopy, cryo EM, molecular genetics, mass spectrometry, live cell tracking and mathematic modelling have been used to develop an understanding of how the direction of rotation of a single flagellar motor is controlled by integrating responses to extracellular and intracellular signals through the two pathways. Recent work suggests that signals from the cytoplasmic cluster dominate and *R. sphaeroides* tunes its swimming behaviour in response to current metabolic requirements.

## **FEMS-2813**

### **Bacterial phosphorylation networks**

#### **Signalling by two-component systems. A structural view**

A. Marina<sup>1</sup>

<sup>1</sup>*Genomic and Proteomic, Instituto de Biomedicina de Valencia (CSIC), Valencia, Spain*

Two-component systems (TCS) are the predominant signal transduction mechanism in bacteria, are present in lower eukaryotes such as fungi and plants, but they are absent from mammals. The key players in these systems are two proteins, histidine kinases (HKs) along with response regulators (RRs) which transmit signals through phosphoryl-transfer. HKs are sensor dimeric proteins that, upon signal detection, bind ATP and autophosphorylate in a catalytic histidine residue. Transfer of the phosphoryl group from the HK histidine to a conserved aspartic of its cognate RR propagates the signal and triggers the cellular response. Signal cease by the auto or HK-mediated de-phosphorylation of the RR. The catalytic machinery in charge of carrying out the reactions related with signaling process, either in the HK or the RR, is highly conserved and the couple interaction shows high-fidelity. Despite being the more abundant signal transduction systems in the nature, the molecular bases of these reactions are neither fully understood at biochemical level nor well-characterized at structural level, as HK autophosphorylation reaction is known to be conducted via a *cis* or *trans* mechanism in different HKs or the HK-RR phosphoryl transfer and HK-mediated RR de-phosphorylation have been demonstrated not to be reversible. In an effort to clarify the molecular basis of TCS signaling we have worked during the last 10 years with HK853-RR468 and EnvZ-OmpR, two prototypical TCS. Our functional and structural results, which will be discussed in the presentation, shed light on the molecular basis of each reaction and their interrelationship with HK-RR recognition and specificity.

**FEMS-2856**

**Fungal cell biology**

**Molecular motors in spatially organizing the fungal cell**

G. Steinberg<sup>1</sup>

<sup>1</sup>*Biosciences, University of Exeter, Exeter, United Kingdom*

To cause plant disease, pathogenic fungi can secrete effector proteins into plant cells to suppress plant immunity and facilitate fungal infection. Most fungal pathogens infect plants using very long strand-like cells, called hyphae, which secrete effectors from their tips into host tissue. How fungi undergo long-distance cell signalling to regulate effector production during infection is not known. Here, I show that long-distance retrograde motility of early endosomes (EEs) is necessary to trigger transcription of effector-encoding genes during plant infection by the pathogenic fungus *Ustilago maydis*. This motor-dependent retrograde EE motility controls effector production and secretion during host cell invasion. It involves the mitogen-activated kinase Crk1, which travels on EEs and participates in control of effector production. Fungal pathogens therefore undergo endosome-mediated long range-signalling to orchestrate host invasion. These findings add to recent discovery that EEs distribute the machinery for protein translation. Thus, 15 years after the discovery of motile endosomes in fungi, the biological role of their motility is beginning to reveal.

**FEMS-2791**

**Fungal cell biology**

**Peroxisome biogenesis and proliferation in yeast**

I.J. van der Klei<sup>1</sup>

<sup>1</sup>*Molecular Cell Biology, University of Groningen, Groningen, Netherlands*

Peroxisomes are cell organelles that are present in almost all eukaryotic cells. They can harbor a large variety of enzymes, which highly depends on the organism, tissue and developmental stage. Common peroxisomal functions include the beta-oxidation of fatty acids and hydrogen peroxide metabolism. The importance of these organelles is illustrated by the fact that peroxisome malfunction results in severe disorders and is often lethal in man.

In yeast and filamentous fungi peroxisomes play a role in the metabolism of various unusual carbon and organic nitrogen sources, such as alkanes, fatty acids, methanol, primary amines and uric acid. Notably, in filamentous fungi peroxisomes are crucial for the biosynthesis of commercially important metabolites, such as beta-lactam antibiotics.

We study peroxisome biology using *Saccharomyces cerevisiae* and *Hansenula polymorpha* as model organisms. An important and highly debated topic is how new peroxisomes are formed. One model proposes that peroxisomes are semi-autonomous organelles that originate by fission of pre-existing ones, similar to mitochondria. According to an alternative model peroxisomes form de novo from the endoplasmic reticulum, which implies that peroxisomes form a branch of the endomembrane system.

We recently re-investigated both pathways using advanced electron and fluorescence microscopy techniques. Our data suggest that in yeast peroxisome fission is the major mode of peroxisome proliferation.

**Genetic Networks in Budding Yeast**

B. Andrews<sup>1</sup>

<sup>1</sup>*The Donnelly Centre, University of Toronto, Toronto, Canada*

To define the general principles of genetic networks, our group developed a functional genomics platform called 'synthetic genetic array' (SGA) analysis that automates yeast genetics and enables the systematic construction of double and triple mutants. One of our major goals has been to use a simple phenotypic readout of cell growth rate – colony size – to produce the first complete genetic interaction map for any cell, and to empirically delineate the properties of genetic networks. We have now analysed the majority of all possible 18 million yeast gene pairs. The resultant network consists of ~560,000 genetic interactions, spanning 93% of all yeast genes. Analysis of the network has revealed: [1] a central role for and unique properties of essential genes; [2] hubs and pleiotropic genes on the network which show a clear association with several fundamental physiological and evolutionary properties that are predictive of genetic interactions in other organisms; [3] functional modules that we use to predict and test conservation of interactions in other systems.

## **MICROBIO: ON LINE TOOLS FOR TEACHING AND DISSEMINATION MICROBIOLOGY CONCEPTS**

I. López-Goñi<sup>1</sup>

<sup>1</sup>*Microbiología y Parasitología, Universidad de Navarra, Pamplona, Spain*

### **Background**

Teaching and research are main jobs of a university professor. Both tasks should be nourished by public dissemination of scientific matters. Under the acronym of “**microBIO**” I have group together several on line tools for the dissemination and spread news and curiosities about microbiology and science in general.

### **Objectives**

In an understandable and entertaining way, with scientific accuracy, the goals of **microBIO** are: i) make science and microbiology understandable to all kind of people, ii) wake up the curiosity for microbiology and arouse young scientific vocations, iii) avoid the isolation of scientist and increase the visibility of our work.

### **Methods**

**microBIO** get together several tools on line, open and free: blog, twitter, Facebook, Scoop.it, Storify, YouTube channel, TEDx talks,... We use social networks to disseminate and share images, teaching resources, videos, links and all kind of scientific information of interest.

### **Conclusions**

Two experiences have special attention. 1) Massive Online Open Courses (MOOC) as introductory courses of general microbiology and virology: “Microbes around us” and “Pandemics and new viral infections”, both for people with interest in scientist topics, primarily undergraduate students, first-year university course, science teachers and journalists; ii) microbiology master classes by twitter, during 8 weeks, once a week, we share around 30 “tweets” with the hashtag #microMOOC. In only 140 characters we taught different subjects related with microbiology.

**microBIO** has thousands of followers from all over the world, 37% from Spain and

the remainder from other countries: México, USA and Latin-America. **microBIO** demonstrates that microbiology can also be “trending topic”.

**FEMS-1060**

**Education**

## **DEVELOPING EUROPEAN COMMON CURRICULUM FOR MICROBIOLOGY EDUCATION: IS THERE A NEED?**

A. Trchounian<sup>1</sup>

<sup>1</sup>*Microbiology & Plants and Microbes Biotechnology, Yerevan State University, Yerevan, Armenia*

### **Background**

Microbiology including General and Applied Microbiology is main subject in Biology (Microbiology) education at European universities. Microbial Biotechnology is important for training in Biology education and Clinical Microbiology - Medicine one. American Society for Microbiology is developing a curriculum. European common curriculum would be of significance to train specialists on the unified high level.

### **Objectives**

The motivations to train microbiologists in European countries would be clarified; the role of Microbiology in Biology education and main parts in Microbiology content should be defined.

### **Methods**

Education practice in Bologna process framework as well as American, European national or university curriculums would be compared and analysed.

### **Conclusions**

To have European common curriculum the following would be of significance:

- for motivations: description and preservation of wide biodiversity, including microorganisms, in different regions in Europe; isolation, identification and study of microorganisms in different ecological environment, discovering their role in nature; monitoring and control of potentially dangerous microorganisms in nature and among habitants, developing new strategy against endemic pathogens; using microorganisms in food and pharmaceutical industry; developing bio-energy production; control of biosafety; biology education at secondary schools.
- Three modules are significant for education: Biodiversity, including biology of microorganisms; Physiology, including microbial physiology; Physico-Chemical

Biology. General (Basic and Systematic) Microbiology and Microbial Biotechnology and/or Clinical Microbiology can be recommended as main topics.

- For teaching issues improving computer and lab works would be efficient in learning Microbiology and developing appropriate practical skills.

To have acceptable curriculum and to implement in different countries, adoption by FEMS (Education Group) would be important.

**FEMS-2642**

**Education**

## **DELIVER MICROBIOLOGICAL CONCEPTS TO A GENERAL AUDIENCE WITH AN ANIMATED CARTOON**

F. Villa<sup>1</sup>, C. Di Giulio<sup>2</sup>, P. Dirckx<sup>3</sup>, P. Stewart<sup>3</sup>, F. Cappitelli<sup>1</sup>

<sup>1</sup>*Dipartimento di Scienze per gli Alimenti la Nutrizione e l'Ambiente, Università degli Studi di Milano, Milano, Italy*

<sup>2</sup>*Scuola di cinema e televisione, Fondazione Milano, Milano, Italy*

<sup>3</sup>*Center for Biofilm Engineering, Montana State University, Bozeman, USA*

### **Background**

As stated by the European Charter for Researchers, scientists should ensure that their research activities are made known to society at large in such a way that they can be understood by non-specialists, thereby improving the public's understanding of science (EC 2005). Science communication is considered a fundamental tool to promote science study, to raise the visibility of universities and their research groups, and to influence policy decisions and funding opportunities.

### **Objectives**

The aim of this work was to create an animated cartoon to raise awareness among young people, citizens, end-users and policy makers about the significance and the broad impacts of the EU funded project ESENCYA "Environmental SENSory perception in CYAnobacterial biofilms: understanding biodeterioration of outdoor stone materials in a changing environment".

### **Methods**

By working with a multifunctional team composed of character designers, visual development artists, communication specialists and scientists, we created a visually engaging story about complex concepts in new and innovative ways (Fig. 1). We translated complex information and ideas into intuitive and effective visual explanations, and we used a narrative strategy to get our message across, clearly and concisely while reducing misunderstanding.

Fig. 1: frames of the animated cartoon.

## Conclusions

This animated cartoon wants to encourage and inspire actions directed towards raising public awareness of the importance of sciences for our contemporary society in a cultural and historical perspective. The microbiology community, in Europe and around the world, can find ideas, blueprints and suggestions for activities directed towards raising public awareness of science, technology and other fields where microbiology plays a strong role.

**FEMS-1167**

**Food biotechnology**

***Clostridium botulinum* and the safety of modern foods**

M. Peck<sup>1</sup>

<sup>1</sup>*Gut Health and Food Safety, Institute of Food Research, Norwich, United Kingdom*

Foodborne botulism is a severe and often fatal neuromuscular intoxication caused by consumption of neurotoxin formed by strains of *Clostridium botulinum* (and very occasionally by strains of *C. baratii* or *C. butyricum*). *C. botulinum* is defined on the basis of one physiological property, an ability to form botulinum neurotoxin. It is a heterogeneous species that is separated into four distinct phylogenetic/physiological groups (*C. botulinum* Groups I to IV). The distinction between each Group is sufficient to merit separation into different species. Seven botulinum neurotoxins (types A to G), and >30 neurotoxin sub-types are recognised. The botulinum neurotoxins are the most potent toxins known; 50ng of neurotoxin may cause human illness and possibly death.

*C. botulinum* Groups I and II and the neurotoxins they form (types A, B, E and F) are responsible for most cases of foodborne botulism. These two physiologically distinct bacteria present different problems. *C. botulinum* Group I (proteolytic *C. botulinum*) is a mesophile (minimum growth temperature 10°C-12°C) that forms highly heat resistant spores, while *C. botulinum* Group II (non-proteolytic *C. botulinum*) is a psychrotroph (minimum growth temperature 2.5°C-3.0°C) that forms moderately heat resistant spores.

Recent advances in genomics have increased understanding of the biology of *C. botulinum* Groups I and II, while developments in mathematics have improved risk assessments. The safe development of novel foods and new food processes requires strong control measures for *C. botulinum* Groups I and II. The extreme severity of foodborne botulism ensures that regulators and industry remain vigilant to minimize the foodborne botulism risk.

**FEMS-2426**

**Food biotechnology**

**NEW INSIGHT INTO BIOGENIC AMINES: TOWARDS SOLUTION AND BIOTECHNOLOGICAL APPLICATIONS**

M. Fernández<sup>1</sup>, V. Ladero<sup>1</sup>, D.M. Linares<sup>1</sup>, B. del Río<sup>1</sup>, M. Díaz<sup>1</sup>, M. Perez<sup>1</sup>,  
M.C. Martín<sup>1</sup>, M.A. Alvarez<sup>1</sup>

<sup>1</sup>*Technology and biotechnology of dairy products, IPLA-CSIC, Villaviciosa, Spain*

**Background**

Biogenic amines (BA) are low molecular weight nitrogenous compounds mainly formed by the microbial decarboxylation of amino acids. The primary relevance of BA is that the consumption of foods or beverages containing high concentration of BA may cause food intoxication. Dairy products are among the foods likely to contain the highest concentrations of BA, being lactic acid bacteria the main BA-producers.

**Objectives**

Increase our knowledge on BA synthesis in order to adopt strategies for surveillance and prevention of BA accumulation in foods and towards the development of new biotechnological tools.

**Methods**

Strategies to reduce the BA content in fermented products:

- Avoid the presence of bacteria synthesizing BA through the food chain. The identification of BA gene clusters has allowed the design of molecular methods to identify and quantify the presence of BA producers in cheese samples.
- Identify key factors which favor BA accumulation. Different physicochemical and technological factors have been studied in order to determine their impact on BA accumulation either affecting bacterial growth or BA gene expression.
- Recently, the use of biogenic amine-degrading microorganisms has been proposed. It is necessary to identify and select highly competitive adjunct cultures capable of in situ reduce the content of BA during the elaboration of fermented products.

Beside of this, understand the transcriptional regulation of BA synthesis clusters offer opportunities for the development of new expression vectors.

**Conclusions**

The study of BA synthesis, is needed to propose new strategies to avoid BA accumulation in foods and can be used for the development of new biotechnological tools.

**FEMS-2374**

**Food biotechnology**

**THE PHAGE ENDOLYSIN LYSTP712 REQUIRES A FUNCTIONAL HOST MEMBRANE PROTEASE FTSH TO LYSE LACTOCOCCAL HOST CELLS**

B. Martínez<sup>1</sup>, C. Roces<sup>1</sup>, U. Wegmann<sup>2</sup>, A.B. Campelo<sup>1</sup>, S. Escobedo<sup>1</sup>, P. García<sup>1</sup>, A. Rodríguez<sup>1</sup>

<sup>1</sup>Technology and Biotechnology of Dairy Products, IPLA-CSIC, Villaviciosa-Asturias, Spain

<sup>2</sup>Gut Health and Food Safety Programme, Institute of Food Research, Norwich, United Kingdom

**Background**

Bacteriophages are often the cause of milk fermentation failures and selecting phage resistant starters, namely *Lactococcus lactis* which is widely use in cheese manufacturing, may reduce the risk. *L. lactis* lacking the membrane protease FtsH became resistant to the phage TP712. In these mutants, viable phages amassed in the cytoplasm but could not be released.

**Objectives**

Lysis of the phage host is usually accomplished by the action of two phage proteins: a holin that disrupts the cytoplasmic membrane and an endolysin that degrades the peptidoglycan. Our objective was to demonstrate if the activity of any of these proteins was compromised by the absence of FtsH.

**Methods**

TP712 lysogens were induced with mitomycin C and treated with ionophores to simulate holin activity. Contrary to the wildtype strain, lysis was not triggered in *L. lactis*  $\Delta$ ftsH, pointing to a failure of the endolysin to degrade the cell wall. However, zymograms revealed the presence of an active LysTP712 endolysin in *L. lactis*  $\Delta$ ftsH lysogens. A fusion protein consisting of the fluorescent mCherry protein and the cell wall binding domain of LysTP712 fused to its C-terminus was synthesized in *E. coli* and purified. Binding experiments to whole cells demonstrated that the fusion protein localized at the septum in both WT and  $\Delta$ ftsH lactococcal cells but the latter bound 40% less protein.

**Conclusions**

Absence of FtsH does not compromise proper functioning of the TP712 holin.

LysTP712 synthesized in *L. lactis*  $\Delta$ ftsH is active *in vitro* but its binding to *L. lactis*  $\Delta$ ftsH cells is reduced.

Waclaw Dabrowski Institute of Agricultural and Food Biotechnology, Warsaw, Poland

<sup>3</sup>Department of Biotechnology Microbiology and Food Evaluation,

Warsaw University of Life Sciences, Warsaw, Poland

### **Background**

Transglutaminase is used in different branches of the industry because of its ability to modify physicochemical properties of proteins. It can be the solution to many technological problems related to appropriate efficiency and food texture. Transglutaminase catalyses the formation of cross-links both within a protein molecule and between molecules of different proteins. In bakery industry it was found that at certain level of transglutaminase concentration it has a significant influence on the dough by increase of relaxation time of doughs. Taking into consideration fact that high relaxation times in general correspond to a high quality flour it is believed that transglutaminase would help improve the quality of weak flours.

### **Objectives**

The aim of the experiment is to determine transglutaminase influence on wheat bread quality.

### **Methods**

Transglutaminase was obtained from *Streptoverticillium mobaraense* strain KKP 2013 obtained from Culture Collection of Industrial Micro-organisms. Preparations were sprayed dried on maltodextrin as carrier. In the experiments there were used wheat flour type 500, two preparations of transglutaminase in four level of addition: 0.01%; 0.05%; 0.25% and 0.5. All physicochemical parameters were determined according to Polish and European Standards.

### **Conclusions**

Taking into consideration crumb characteristics there has been shown an increase in hardness and chewiness, explained as a result of an improvement in the structure of the crumb in comparison to a control breads. The quality of bread in the organoleptic

evaluation was not very diverse. Although the bread with the addition of transglutaminase received higher number of points than the bread without enzyme.

**FEMS-0574**

**Food biotechnology**

## **OXIDATION OF FERULIC ACID TO FORM DIMERS WITH HIGHER ANTIOXIDANT CAPACITY**

O. Adelakun<sup>1</sup>

<sup>1</sup>*fse, lautech, ogbomosho, Nigeria*

### **Background**

Ferulic acid is an abundant and widespread cinnamic acid derivative with antioxidant properties. However, its antioxidant activity is generally low when compared to conventional antioxidants, such as butylated hydroxyanisole (BHA) and other hydroxyl-cinnamic acids, such as sinapic acid. Laccases (EC 1.10.3.2) are enzymes that are capable of catalysing the oxidation of various phenolic compounds with the production of water as the only by-product, and are therefore often referred to as 'green' enzymes. The use of laccases in the oxidative coupling and polymerisation of phenolic compounds offers potential for the amplification of the antioxidative capacity of these phenolic compounds.

### **Objectives**

This work employed the use of laccase produced from *Trametes pubescens* to catalyse the modification of ferulic acid as a way of enhancing antioxidant capacity.

### **Methods**

An airlift reactor was used to produce laccase from free cells of *Trametes pubescens* and the laccase was purified. Reaction of ferulic acid (10mM) with laccase (10 U) was done at 28°C in a biphasic system of ethyl acetate and 100mM sodium acetate buffer pH 5.0. Products were separated, purified, characterized and antioxidant activities were determined.

### **Conclusions**

This work elucidates the structure of two dimers formed from ferulic acid in organic media one of which is more potent than ferulic acid in terms of antioxidant activity. This new product could find useful application in health and cosmetic industry.

<sup>2</sup>INSERM E0230, University of Lyon, Lyon, France

*Staphylococcus aureus* is a remarkable versatile pathogen, able to cause a wide spectrum of human diseases, and is one of the main causes of community as well as hospital-acquired infections. The contribution of regulatory RNAs in the establishment of virulence in this pathogen is increasingly appreciated. Our previous data emphasize the multitude of regulatory steps affected by RNAIII in establishing a network of *S. aureus* virulence factors. We show that RNAIII coordinately represses the expression of numerous mRNAs that encode the transcriptional repressor of toxins, several virulence factors acting early in the infection process, and enzymes involved in peptidoglycan metabolism. Besides RNAIII, we demonstrated that the *S. aureus* genome likely encodes a high diversity of RNAs including *cis*-acting regulatory regions of mRNAs, *cis*-acting antisense RNAs, and small RNAs. One of these sRNAs attenuates the severity of acute systemic infections and enhances chronic catheter infection by regulating MgrA, a transcriptional regulator of capsule formation. Because *S. aureus* is essentially a human commensal, we propose that RsaA has been positively selected through evolution to support commensalism and saprophytic interactions with the host. We will also illustrate how regulatory proteins and RNAs form complex regulatory circuits to express the virulence factors in a dynamic manner.

**Signalling, small RNAs and regulation: virulence aspects**

**RNA-mediated regulation of Legionella virulence**

C. Buchrieser<sup>1</sup>

<sup>1</sup>*Genomes and Genetics, Institut Pasteur, Paris, France*

*Legionella pneumophila*, a gram-negative intracellular pathogen, has evolved complex mechanisms to efficiently enter, replicate inside, and evade their hosts, aquatic amoebae or alveolar macrophages during disease. *L. pneumophila* has been shown to cycle between an infectious, non-replicating form thought to promote transmission to a new host, and an intracellular, replicative form, which does not express transmission/virulence traits. This biphasic lifecycle is tightly regulated by a complex regulatory cascade, implicating two component systems, sigma factors, RNA binding proteins and small ncRNAs. Here we have employed RNAseq, transcriptional start site (TSS) mapping and RIPseq combined with molecular biology approaches to better understand this regulatory network and the implication of ncRNAs. We first established a genome-wide map of the TSSs and operons for *L. pneumophila*, and identified over 500 new small ncRNAs that may act as potential regulators of cis- and trans-encoded target messenger RNAs. Among those a high amount of antisense transcription was observed. A detailed search for targets of the RNA-binding protein CsrA, a key regulator in the expression of the virulence phenotype of *L. pneumophila* led to the identification of over 50 mRNAs regulated by CsrA, many of which are virulence related proteins. Taken together, we identified the mRNA targets of the RNA binding protein CsrA, ncRNAs regulating CsrA as well as ncRNAs implicated in virulence. Furthermore we showed that tandem promoters and sRNAs with alternative usage are a hallmark of the life cycle depend virulence gene expression of *L. pneumophila*.

## **REGULATION OF THE TYPE I-F CRISPR-CAS SYSTEM OF PECTOBACTERIUM ATROSEPTICUM**

A.G. Patterson<sup>1</sup>, J.T. Chang<sup>1</sup>, R.E. McKenzie<sup>1</sup>, P.C. Fineran<sup>1</sup>

<sup>1</sup>Microbiology and Immunology, University of Otago, Dunedin, New Zealand

### **Background**

The CRISPR-Cas 'prokaryotic adaptive immune system' represents an intricate defence strategy allowing bacteria to protect themselves against invading genetic elements such as bacteriophages or plasmids. Through the acquisition of short segments of invading nucleic acid sequences into genomic CRISPR loci, this system provides a heritable genetic memory of previous exposure and, in combination with various CRISPR-associated (cas) proteins, a means by which the bacteria can specifically recognise, target and eliminate the exogenous threat. In the past 10 years since the discovery of CRISPR-Cas systems, there has been a heavy focus on functionality; how the acquisition of genetic material occurs and how the system coordinates its targeted response. In contrast, very little is known how about how CRISPR-Cas systems are regulated and of the limited literature available, it seems that a universal mode of regulation is perhaps unlikely.

### **Objectives**

In this study, we focused on elucidating the regulatory control of the model Type I-F system in *Pectobacterium atrosepticum*.

### **Methods**

Unbiased transposon mutagenesis of a cas1 reporter strain was utilised to identify mutants exhibiting differential promoter activity compared with a wildtype control. CRISPR-Cas activity was also assessed in these mutant strains via conjugation efficiency and spacer acquisition assays.

### **Conclusions**

We have identified a network of regulators of CRISPR-Cas expression, highlighting a link to global regulators that sense the nutritional status of the cell. In addition, we have shown that mutating these regulators drastically affects both the primed acquisition and interference stages within CRISPR-Cas-mediated defence.

## **PROTEOLYSIS OF ANTI-SIGMA FACTORS IN THE TRANSDUCTION OF THE SIGNAL AND ACTIVATION OF EXTRACYTOPLASMIC FUNCTION SIGMA FACTORS**

*K.C. Bastiaansen<sup>1</sup>, J.R. Otero-Asman<sup>2</sup>, W. Bitter<sup>1</sup>, M.A. Llamas<sup>2</sup>*

*<sup>1</sup>Molecular Cell Biology, VU University Amsterdam, Amsterdam, Netherlands*

*<sup>2</sup>Environmental Protection, Estación Experimental del Zaidín-  
Consejo Superior de Investigaciones Científicas, Granada, Spain*

### **Background**

Regulation of gene expression allows bacteria to adapt to alterations in their environment. This regulation occurs mainly at the level of transcription initiation by modifying promoter recognition of the RNA polymerase, a recognition that is primarily modulated by substitution of the RNAP sigma subunit. Besides a primary sigma factor responsible of the expression of general functions, most bacteria contain alternative sigma factors that target expression of functions required only under specific circumstances. Of those, the extracytoplasmic function sigma factors ( $\sigma^{\text{ECF}}$ ) represent the largest group, and control expression of bacterial functions as important as stress responses, iron uptake and virulence.

### **Objectives**

Activation of  $\sigma^{\text{ECF}}$  is a tightly regulated process that usually occurs in response to environmental signals, a control that is carried out by anti-sigma factors. Binding of the  $\sigma^{\text{ECF}}$  to the RNAP and the anti-sigma factor is mutually exclusive. This work focusses on understanding the molecular mechanism behind  $\sigma^{\text{ECF}}$  activation.

### **Methods**

We have used *Pseudomonas* as bacterial model and a number of in vivo and in vitro techniques to monitor gene expression and protein levels, stability and structure.

### **Conclusions**

Activation of  $\sigma^{\text{ECF}}$  in response to the inducing signal requires the processing of the anti-sigma factor by a complex proteolytic cascade that involves, amongst other, the Prc and RseP proteases. Interestingly, several anti-sigma factors undergo self-cleavage prior to signal recognition by an enzyme-independent process. This cleavage produces two functional domains that interact and function together to transduce the presence of the signal and to activate the  $\sigma^{\text{ECF}}$ . The biological significance of this widespread mechanism is discussed.

**RESPONSE OF YEDQ DIGUANYLATE CYCLASE TO PYRIMIDINE NUCLEOTIDES BY DIRECT INTERACTION WITH THE METABOLIC ENZYME ASPARTATE CARBAMOYLTRANSFERASE AND ITS METABOLIC PRODUCT N-CARBAMOYL-L-ASPARTATE**

E. Rossi<sup>1</sup>, P. Landin<sup>2</sup>

<sup>1</sup>*Istituto di Chimica del Riconoscimento Molecolare,  
Consiglio Nazionale delle Ricerche, Milano, Italy*

<sup>2</sup>*Dipartimento di Bioscienze, Università degli Studi di Milano, Milano, Italy*

**Background**

In *Escherichia coli*, formation of multicellular communities is mediated by the production of adhesion factors such as curli fibres and the extracellular polysaccharide cellulose. Synthesis of curli fibres and cellulose is co-regulated through the activity of the transcriptional factor CsgD and is under the control of several extracellular and intracellular signals, including the second messenger c-di-GMP. We demonstrated that curli and cellulose production are tightly linked to pyrimidine biosynthetic pathways. Indeed, transcription of curli operons is strongly affected by pyrimidine nucleotide availability; in addition, we found that exogenous uracil can trigger cellulose production independently of CsgD, by increasing c-di-GMP levels via the YedQ diguanylate cyclase.

**Objectives**

Through a combined *in vivo* and *in vitro* approach we studied the molecular mechanism underlying the uracil-dependent regulation of YedQ.

**Methods**

YedQ protein interactors were co-purified using his-tag pull-down technique and then identified through MudPIT technology. Interactions were validated using bacterial two-hybrid assay. Protein ligand binding was determined through differential scanning fluorimetry, while gene expression was measured with qRT-PCR assay.

**Conclusions**

We found that YedQ can directly interact with aspartate carbamoyl-transferase (PyrBI), an essential enzyme involved in pyrimidine nucleotides biosynthesis, in a manner dependent on uracil availability, and can also bind N-carbamoyl-L-aspartate the product of PyrBI enzyme. We hypothesise that aspartate carbamoyltransferase

and/or N-carbamoyl-L-aspartate can inhibit YedQ diguanylate cyclase activity by directly interacting with its cytoplasmic domain and this negative effect can be reversed by uracil. The YedQ/PyrBI interaction might represent a model of how activity of metabolic pathways can be coupled to a c-di-GMP signalling system.

**A NEW TARGET FOR THE SRNA OMRA: THE VIRF MRNA IN SHIGELLA FLEXNERI**

M.L. Di Martino<sup>1</sup>, C. Romilly<sup>2</sup>, E.G.H. Wagner<sup>2</sup>, B. Colonna<sup>1</sup>, G. Prosseda<sup>1</sup>

<sup>1</sup>Department of Biology and Biotechnology "C. Darwin",  
Sapienza - University of Rome - Istituto Pasteur Fondazione Cenci Bolognetti, Rome,  
Italy

<sup>2</sup>Department of Cell and Molecular Biology, Uppsala University, Uppsala, Sweden

**Background**

VirF is a transcriptional regulator which plays a central role in controlling virulence gene expression in *Shigella* spp, the ethiological agent of bacillary dysentery in humans. VirF protein is present in two different forms, independently translated. VirF<sub>30</sub> is responsible for activation of the virulence system and some chromosomal genes, whereas VirF<sub>21</sub> exerts negative feedback control on *virF* expression itself.

**Objectives**

This work investigates the role of OmrA, a sRNA induced under high osmolarity conditions, on the translation of VirF<sub>21</sub> and its impact on *Shigella* virulence.

**Methods**

In vitro translation, translational lacZ –fusions, OmrA overexpression were used to evaluate the effect of OmrA on VirF<sub>21</sub> translation. RNA footprinting was performed to map the OmrA binding site on *virF* mRNA.

**Conclusions**

We have provided evidence supporting the involvement of OmrA in the translational regulation of *Shigella* VirF. In particular, we have shown that under high osmolarity conditions the expression of a VirF<sub>21</sub> fusion is decreased severely in *E.coli* wt as compared to a defective *omrBA* derivative. Overexpression of OmrA, but not of OmrB, leads to a strong decrease in VirF<sub>21</sub> translation. We also performed RNA footprinting showing the precise binding site of OmrA on *virF* mRNA. These data suggest that OmrA might interfere with the translation of the *virF* mRNA, reducing the amount of VirF<sub>21</sub> peptide. The result of this complex regulation is a fine-tuned expression of virulence genes, allowing *Shigella* a prompt adaptation to different environments and conditions.

### **Fungal human pathogens**

#### **Components of the fungal cell wall that turn on and turn off the immune inflammatory response**

N.A.R. Gow<sup>1</sup>

<sup>1</sup>*Institute of Medical Sciences, University of Aberdeen, Aberdeen, United Kingdom*

The fungal cell wall defines the perimeter of its own self and a boundary of communication with other organisms with which it interacts. For a fungal pathogen, every component and layer of the cell wall plays a specific role in its interactions with cells of the human host. We have tried to peel the functions of cell wall components by combining genetics, biochemistry and immunology to understand how the wall is assembled and how its constituents are recognized by the human immune system. This work has shown how the polysaccharides of the cell wall activate both the inflammatory and anti-inflammatory responses of the innate immune system.

Chitin is an essential polysaccharide of the walls of all fungal pathogens and the exoskeleton and eggs of invertebrate parasites. We identified NOD2, TLR9 and the mannose receptor as three essential fungal chitin-recognition receptors of innate immune cells and showed that the activation of NOD2/TLR9 receptors by low concentrations of small chitin particles, generated via the action of human chitinases, leads to selective secretion of the anti-inflammatory cytokine IL-10. In contrast, higher concentrations of chitin particles promoted a pro-inflammatory response via dectin-1-TLR2 signalling. NOD2 and TLR9 polymorphisms are associated with susceptibility to inflammatory conditions such as Crohn's disease, allergy and asthma. Chitin therefore promotes size-dependent anti- and pro-inflammatory immune responses that are critical for immune homeostasis, but can also promote the development of asthma and allergy.

**Pathogenicity and immune evasion of the human-pathogenic fungus**

***Aspergillus fumigatus***

A. Brakhage<sup>1</sup>

<sup>1</sup>Molecular and Applied Microbiology,

Leibniz Institute for Natural Product Research and Infection Biology,

(HKI) and Institute of Microbiology, Friedrich Schiller University Jena, Germany

## **Background**

The filamentous fungus *Aspergillus fumigatus* is the most important air-borne fungal pathogen causing 90 % of all systemic *Aspergillus* infections in humans. The most severe disease caused by *A. fumigatus* is invasive aspergillosis which almost exclusively occurs in immunocompromised patients. A lack of reliable diagnostic tools and effective treatment options results in high mortality rates despite therapy.

## **Objectives**

We aim at identifying pathogenicity determinants and mechanisms how *A. fumigatus* can overcome the response of immune effector cells.

## **Methods**

Transcriptome, (immune)proteome analyses including systems biological analyses with subsequent generation of deletion mutants and their analysis in processing by the immune system like neutrophilic granulocytes, alveolar macrophages and complement; test of mutants in a mouse infection model.

## **Conclusions**

*A. fumigatus* has developed immune evasion mechanisms which interfere at the different levels of the infection process with the response of the human host. These include recognition of conidia, modulation of phagocytosis, intracellular processing, neutrophil extracellular trap formation, and complement activation. We have identified several molecules including surface components such as proteins and dihydroxynaphthalene melanin as well as secondary metabolites, which manipulate the immune response.

**FIRST METABOLIC NETWORK OF THE SEBORRHEIC DERMATITIS  
ASSOCIATED YEAST *MALASSEZIA FURFUR***

S. Triana<sup>1</sup>, A. González<sup>2</sup>, S. Restrepo<sup>1</sup>, A. Celis<sup>1</sup>

<sup>1</sup>Biological Sciences, Universidad de los Andes, Bogotá, Colombia

<sup>2</sup>chemical Engineering, Universidad de los Andes, Bogotá, Colombia

**Background**

Yeasts in the genus *Malassezia* are part of the skin microbiota of humans and other mammals. These commensal yeasts are related to several disorders including dandruff, seborrheic dermatitis and pityriasis versicolor. However, little is known about the pathogenesis process of *Malassezia* and its metabolism in these skin diseases, especially at the molecular level.

**Objectives**

In this study, we aim to describe the characteristics of *Malassezia furfur* genome-scale metabolic network

**Methods**

For this, a bioinformatics annotation methodology and a (LC/MS)-based shotgun proteomics profiling were used to characterize the 15.7 Mb genome and the subsequent assignment of the reactions and metabolites.

**Conclusions**

A total of 757 proteins were found in the proteomic profiling and were used with previous reports to annotate the genome, achieving a first draft of the metabolic network of this yeast. Metabolic reconstruction predicts an interesting degeneracy on the objective function, reflecting several mechanism for the yeast survival as we identified a relatively low number of genes related to lipid biosynthesis but several genes encoding lipid-hydrolyzing enzymes. These enzymes that could have a role in the pathogenesis of the yeast.

**Fungal human pathogens**

**IMMUNIZATION WITH ANTIGEN DISPLAYED MICROBIAL CELLS BY MOLECULAR DISPLAY TECHNOLOGY AGAINST CANDIDIASIS**

S. Shibasaki<sup>1</sup>, M. Ueda<sup>2</sup>

<sup>1</sup>General Education Center, Hyogo University of Health Sciences, Kobe, Japan

<sup>2</sup>Graduate School of Agriculture, Kyoto University, Kyoto, Japan

**Background**

The administration of caspofungin, micafungin, anidulafungin, and amphotericin B are often involved in pharmacotherapy of candidiasis. Unfortunately, mutants of *Candida* species with reduced susceptibility to these drugs have emerged. Therefore, prevention of infection by vaccination against *Candida* species is thought to be important complementary method to pharmacotherapy of candidiasis.

**Objectives**

*Candida albicans* enolase 1 (Eno1) has been reported a lot as an immunodominant antigen. To develop a convenient and novel type of vaccine against candidiasis, we designed microorganism cells displaying Eno1p as a model antigen on *Saccharomyces cerevisiae* and *Lactobacillus casei* surfaces, respectively [1,2].

**Methods**

The Eno1p-displayed *S. cerevisiae* and *L. casei* cells were constructed by molecular display technology [3]. Eno1 protein was genetically fused to each cell wall proteins to be displayed on these surfaces. Delivery of the cells to mice by oral or intranasal administration increased the titers of anti-Eno1p antibodies and prolonged the lives of mice infected with lethal levels of *C. albicans* [1,2].

**Conclusions**

In this study, only availability of a genetic sequence that encodes the antigenic proteins is needed to produce oral vaccine based on molecular display technology. Because a vaccine produced using molecular display technology avoids the need for protein purification, this oral vaccine offers a promising alternative to the use of conventional vaccines for preventing a range of infectious diseases.

<sup>3</sup>Oral Biosciences Faculty of Dentistry, The University of Hong Kong, Hong Kong, Hong Kong China

<sup>4</sup>School of Dentistry, University of Queensland, Brisbane, Australia

**Background**

Nasopharyngeal carcinoma (NPC) is endemic in Southern China. Intensity-modulated radiation therapy (IMRT) for NPC may damage the salivary glands and lead to xerostomia, providing an ideal environment for opportunistic candidial infections.

**Objectives**

We prospectively investigated the incidence and factors correlating with oral candidial infection in NPC patients treated with radical IMRT.

**Methods**

Forty five patients with non-metastatic NPC were prospectively recruited. Saliva and mouthrinse samples were saved at baseline and then two-weekly during IMRT. They all received IMRT with 70Gy in 33 to 35 fractions over 7 weeks concurrent with cisplatin chemotherapy. Besides the gross tumour and positive neck nodes, the parotids, submandibular and sublingual glands were contoured on Eclipse Treatment Planning System™ for radiation dose calculation. Fungal culture was performed on Sabouraud dextrose agar and CHROMagar™. In addition, API-32C AUX method and species-specific Taqman probes were used for specific identification of *Candida* species. Considerable number of patients i.e. 9 (20.0%) and 25 (55.6%) patients had clinical diagnosis of oral candidiasis and positive candidial culture respectively during IMRT. *C. parapsilosis* (24 patients, 53.5%) followed by *C. albicans* (18 patients, 40.0%) were most commonly found. Grade 2 and 3 xerostomia were noted in 13 (28.9%) and 32 (71.1%) patients respectively. Univariable and multivariable analysis

revealed that mean radiation dose to the parotids  $\geq 45\text{Gy}$  was the only factor ( $p=0.045$  and  $p=0.043$  respectively) correlating significantly with occurrence of oral candidial infection.

## **Conclusions**

Present study demonstrated that IMRT to the parotids may predispose to oral candidial infections which should be taken into account when managing NPC patients.

**FEMS-2601**

**RAPID DETECTION OF CYP51A-PROMOTER BASED VORICONAZOLE RESISTANCE IN ASPERGILLUS FUMIGATUS ISOLATES IN A HIGH INCIDENCE POPULATION**

J. Fuhren<sup>1</sup>, T.T. Severs<sup>1</sup>, W.S. Voskuil<sup>1</sup>, C.H.E. Boel<sup>1</sup>, P.J.A. Haas<sup>1</sup>, J.F. Meis<sup>2</sup>, J.G. Kusters<sup>1</sup>

<sup>1</sup>Medical Microbiology, University Medical Center Utrecht, Utrecht, Netherlands

<sup>2</sup>Medical Microbiology and Infectious Diseases, Canisius-Wilhelmina Hospital, Nijmegen, Netherlands

**Background**

Due to increased azole resistance, first line treatment with voriconazole of *Aspergillus fumigatus* infections in humans is increasingly difficult. Susceptibility testing is essential but culture based resistance determination takes up to two weeks. Resistance is predominately based on mutations in *cyp51A* and duplications of the promoter region (TR34 & TR46).

**Objectives**

To develop a rapid molecular method to screen for azole resistance in *A. fumigatus*.

**Methods**

Azole susceptibility profiles and *cyp51A* genotypes were determined in 105 isolates of 105 consecutive high-risk patients. A probe-based multiplex qPCR was designed and evaluated. This qPCR specifically amplifies the promoter region of *cyp51A* and uses a *cyp51A* control probe and probes for the TR34 and TR46 voriconazole resistance associated promoter duplications.

**Conclusions**

24/105 (22.9%) of the patient isolates had elevated voriconazole MICs. Sequencing of *cyp51A* showed that in 18/24 (75%) isolates the resistance was associated with mutations in the *cyp51A* ORF and had a tandem repeat duplication in the promoter region, identifying this as the main resistance mechanism. The qPCR detected 18 of the 18 isolates in which ORF mutations and promoter duplication were present. The 6 resistant isolates that lacked duplications in the promoter region, as well as all sensitive strains were not detected by the PCR. The probe-based multiplex qPCR delivers a rapid method for the identification of the majority of azole resistant *A. fumigatus* isolates, and offers a rapid pre-screen for detection of voriconazole resistance in a routine clinical routine setting.

**Cell-cell communication / Quorum sensing: inhibition as novel therapeutic tool**

**Quorum quenching acylases for reducing bacterial virulence**

W.J. Quax<sup>1</sup>, G. Koch<sup>1</sup>, P. Nadal Jimenez<sup>1</sup>, P. Utari<sup>1</sup>, R.H. Cool<sup>1</sup>, M. Bokhove<sup>2</sup>,  
B.W. Dijkstra<sup>2</sup>

<sup>1</sup>Pharmaceutical Biology, University of Groningen, Groningen, Netherlands

<sup>2</sup>Biophysical Chemistry, University of Groningen, Groningen, Netherlands

The observation that acylases from the NTN-hydrolase family can cleave the amide bond between acyl side chains and the homoserine lacton moiety of bacterial signalling molecules has raised novel options for interfering with quorum sensing and the onset of virulence. NTN-hydrolases that have initially become known by their paradigm representatives penicillin and cephalosporin acylase appear to be very abundantly encoded in bacterial genomes. Intriguingly the *Pseudomonas aeruginosa* genome contains not less than 4 NTN-hydrolases. The acylase PvdQ is extremely effective in quorum-quenching, hydrolysing bacterial N-acylhomoserine lactones at very low concentrations. Exogenously added PvdQ can reduce the virulence and we have determined its 3D structure. QuiP and HacB are two other acylases hydrolyzing a subset of the signalling molecules of Gram-negatives, C12-HSL and 3-oxo-C12-HSL. The hydrolytic activity of PvdQ is the highest for long-chain AHLs such as 3-oxo-C12-HSL and decreases with shorter acyl chain length, with hardly any activity for C8-HSL. A structure-based approach was applied to evolve this enzyme into an effective quorum quencher of the communication molecule (C8-HSL) of *Burkholderia* species, opportunistic pathogens commonly isolated together with *P. aeruginosa* from patients suffering from cystic fibrosis. Two point mutations in the active centre of PvdQ were found to increase the activity of this enzyme towards C8-HSL. The combination variant displayed high hydrolytic activity towards C8-HSL when compared to wild-type PvdQ. The effects could be strongly correlated in vivo, as exogenous addition of this mutant led to a significant decrease of autoinducers present in *Burkholderia cenocepacia* cultures, and effectively reduced its virulent phenotype.

**Cell-cell communication / Quorum sensing: inhibition as novel therapeutic tool**

**Chemical Interception of Bacterial Quorum Sensing: New Languages, New Outcomes**

H. Blackwell<sup>1</sup>

<sup>1</sup>Chemistry, The University of Wisconsin, Madison, USA

We are developing chemical tools that attenuate cell-cell communication pathways in bacteria. Many bacteria communicate using small organic molecules and peptides to monitor their population densities in a process called “quorum sensing.” At high cell densities, bacteria use this signaling network to switch from an isolated, nomadic existence to that of a multicellular community. This lifestyle switch is significant; only in groups will pathogenic bacteria turn on virulence pathways and grow into drug-impervious communities called biofilms that are the basis of myriad chronic infections. In turn, certain symbiotic bacteria will only initiate host-beneficial behaviors at high population densities. The molecular mechanisms of these processes are only now being delineated. Our research is broadly focused on the design and chemical synthesis of non-native ligands that can intercept quorum sensing and provide new insights into its role in host/microbe interactions. We have developed a series of efficient synthetic methods that provide us with straightforward access to these ligands. In addition, we have applied both quorum sensing antagonists and agonists *in vitro* and *in vivo* to investigate quorum sensing as an anti-infective target. Quorum sensing pathways in Gram-negative and Gram-positive bacteria have been our foci, including LuxI/LuxR-type signaling in *Pseudomonas aeruginosa* and agr-type signaling in *Staphylococcus aureus*. This presentation will introduce our research approach and highlight recent results.

**AHL ACYLASE DISRUPTS BIOFILM FORMATION OF NOSOCOMIAL PATHOGEN ACINETOBACTER NOSOCOMIALIS M2**

P.D. Utari<sup>1</sup>, R. van Merkerk<sup>1</sup>, W.J. Quax<sup>1</sup>

<sup>1</sup>Pharmaceutical Biology, University of Groningen, Groningen, Netherlands

**Background**

*Acinetobacter* is a Gram negative pathogen associated with nosocomial infection and multidrug resistance. Biofilm formation, as one of the most important virulence determinants in *Acinetobacter*, is regulated by quorum sensing. Disruption of biofilm formation represents an interesting target for antivirulence drug development. One particular species, namely *Acinetobacter nosocomialis* strain M2 [1] (previously known as *A. baumannii*) produces a wide range of quorum sensing signaling molecule with 3-OH-C12-HSL as the primary AHL.

**Objectives**

The aim of this study was to investigate the efficacy of quorum quenching acylase enzymes in reducing biofilm formation of *A. nosocomialis* M2. Three acylases with different preference of AHLs substrate were used, namely **PvdQ** [2] (prefer long chain AHLs, such as C10-C14 HSL), **PvdQ<sup>Lα146W,Fβ24Y</sup>** [3] (engineered PvdQ, active towards C8) and **QqaR** [4] (active towards C8-C14 HSL).

**Methods**

Static biofilm of *A. nosocomialis* M2 was grown in 96-well plate with or without addition of acylase. The production of biofilm was examined with crystal violet method.

**Conclusions**

The addition of AHL acylase was shown to disrupt biofilm production of *A. nosocomialis* M2, up to 50% reduction compare to control. Interestingly, PvdQ<sup>Lα146W,Fβ24Y</sup> and QqaR are the most effective in biofilm disruption.

## DEVELOPMENT OF QUORUM QUENCHING PEPTIDES TARGETING VIRR/VIRS SYSTEM OF CLOSTRIDIUM PERFRINGENS

R.P. Singh<sup>1</sup>, K. Ohtan<sup>2</sup>, O. Ken-ichi<sup>1</sup>, K. Sonomoto<sup>1</sup>, J. Nakayama<sup>1</sup>

<sup>1</sup>Department of Bioscience and Biotechnology, Kyushu University, Fukuoka, Japan

<sup>2</sup>Department of Bacteriology, University of Kanazawa, Kanazawa, Japan

### Background

*Clostridium perfringens* is an anaerobic gram-positive pathogen and causative agent for gas gangrene as well as necrotic enteritis. *C. perfringens* produces several extracellular enzymes and toxins, such as  $\alpha$ ,  $\theta$  and  $\kappa$  encoded by *plc*, *pfoA*, and *colA*, respectively. A two component regulatory system (TCS), VirR/VirS, controls production of these enzymes and toxins. Recently, we have identified a 5-membered macrocyclic oligopeptide (CLWFT) as an autoinducer (AIP<sub>Cp</sub>) of VirR/VirS TCS.

### Objectives

The VirR/VirS system is an attractive target for the development of anti-pathogenic chemotherapy of *C. perfringens*, because it orchestrates the quorum sensing cascade. To gain effective inhibitor to block the VirR/VirS signal transduction, we begin with drug design and development of peptides antagonist against AIP<sub>Cp</sub>.

### Methods

To develop antagonistic peptides targeting VirR/VirS, each amino acid residue of AIP<sub>Cp</sub> was substituted to different amino acids and their agonist activity, which induces *pfoA* transcription in *agrBD*-null mutant, as well as antagonist activity which inhibits *pfoA* transcription in wild type strain were examined.

### Conclusions

Alanine scanning suggests that whole structure of AIP is involved in agonist activity. Especially, Z-AIP<sub>Cp</sub>-W3A showed neither agonist nor antagonist activity, while AIP<sub>Cp</sub>-F4A solely showed weak but significant antagonist activity, suggesting that Trp-3 and Phe-4 are crucial for receptor binding and receptor activation, respectively. Interestingly, exchange of Trp-3 and Phe-4 yielded a potent antagonist with IC<sub>50</sub> = 0.4  $\mu$ M. Alternately, Z-AIP<sub>Cp</sub>-L2A-T5A also showed a potent antagonist activity of IC<sub>50</sub> = 0.3  $\mu$ M. High potential of these oligopeptides is suggested that these can be significantly used for therapeutic applications.

## NON-SOCIAL ADAPTATION DEFERS A TRAGEDY OF THE COMMONS IN *PSEUDOMONAS AERUGINOSA* QUORUM SENSING

*K.L. Asfahl<sup>1</sup>, J. Walsh<sup>1</sup>, K. Gilbert<sup>1</sup>, M. Schuster<sup>1</sup>*

<sup>1</sup>Microbiology, Oregon State University, Corvallis, USA

### Background

In a process termed quorum sensing (QS), the opportunistic bacterial pathogen *Pseudomonas aeruginosa* uses diffusible signaling molecules to regulate the expression of numerous secreted factors or public goods that are shared within the population. But not all cells respond to QS signals. These social cheaters typically harbor a mutation in the QS receptor gene *lasR* and exploit the public goods produced by cooperators.

### Objectives

Here we show that non-social adaptation under growth conditions that require QS-dependent public goods increases tolerance to cheating and defers a tragedy of the commons.

### Methods

The underlying mutation is in the transcriptional repressor gene *psdR*. This mutation has no effect on public goods expression but instead increases individual fitness by derepressing growth-limiting intracellular metabolism. Even though *psdR* mutant populations remain susceptible to invasion by isogenic *psdR lasR* cheaters, they bear a lower cheater-load than do wild-type populations, and they are completely resistant

to invasion by *lasR* cheaters with functional *psdR*. Mutations in *psdR* also sustain growth near wild-type levels when paired with certain partial loss-of-function *lasR* mutations. Targeted sequencing of multiple evolved isolates revealed that mutations in *psdR* arise before mutations in *lasR*, and rapidly sweep through the population.

### **Conclusions**

Our results indicate that a QS-favoring environment can lead to adaptations in non-social, intracellular traits that increase the fitness of cooperating individuals and thereby contribute to population-wide maintenance of QS and associated cooperative behaviors.

Cell-cell communication / Quorum sensing: inhibition as novel therapeutic tool

## QUORUM SENSING-DEPENDENT REGULATION OF RHAMNOLIPIDS IN BURKHOLDERIA GLUMAE IS NUTRITIONALLY CONDITIONAL

A. Nickzad<sup>1</sup>, E. Déziel<sup>1</sup>

<sup>1</sup>Microbiology, INRS–Institut Armand-Frappier, Laval, Canada

### Background

*Burkholderia glumae* is a phytopathogenic bacterium that uses the LuxR/LuxI-type TofI/TofR Quorum Sensing (QS) system to regulate various functions, including the major virulence determinants toxoflavin and flagella. *B. glumae* also releases surface-active rhamnolipids which, along with flagella, are required for the social behavior called swarming motility in *Pseudomonas aeruginosa* and *Burkholderia thailandensis*.

### Objectives

We investigated the role of rhamnolipids in swarming motility and the interplay between QS and nutrition-based regulation of rhamnolipids production in *B. glumae*.

### Methods

Swarming and swimming assays were carried out to test the motility of various mutants. Analyses of rhamnolipids and N-acyl-homoserine lactones were performed by LC-MS/MS. *rhlA* expression in wild-type and QS-defective *toft* strains was monitored using a *lux* reporter fusion.

### Conclusions

We show that QS positively regulates the production of rhamnolipids in *B. glumae* and these are also necessary for swarming motility in this species. Unexpectedly, the C<sub>8</sub>-HSL-negative *toft* mutant, in contrast with growth in a minimal medium, regains the ability to produce rhamnolipids in a complex nutrient broth medium. Moreover, decreasing nutrient concentrations leads to a major induction in *rhlA* expression in the wild-type strain. However, *rhlA* expression in the *toft* mutant is induced to a lesser extent by nutrient limitations. Under nutrient-limited conditions, QS mediates rhamnolipids biosynthesis, presumably to promote swarming motility. These results indicate that, in contrast with the situation in *P. aeruginosa*, QS regulation of rhamnolipids in *B. glumae* is dispensable and nutritionally conditional.

New insights into the pathogenesis of MTB impacting on the host's immune  
response**

**TB vaccines; on the role of Th1, memory and immunity in the lung?**

P. Andersen<sup>1</sup>

<sup>1</sup>*Vaccine R&D, Statens Serum Institute, Copenhagen S, Denmark*

**TB vaccines; on the role of Th1, memory and immunity in the lung**

*Mycobacterium tuberculosis* and humans have co-evolved since the most early human origin and this has allowed the pathogen to adapt and develop a refined set of countermeasures to the human immune response during infection. The result is a pathogen that is rarely cleared by the natural immune response but instead establishes a long-term chronic infection. Although IFN- $\gamma$  is clearly insufficient for the control of TB in individuals that develop disease, most TB vaccine research have still been focused on immuno-dominant antigens administered in delivery systems that promote strong Th1 responses. Recent breakthroughs in our understanding of requirement for immunological memory and the recruitment and expression of immunity to TB in the lung now provide a framework for reconsidering that strategy.

I will discuss recent data from mouse and non-human primate models of vaccine promoted protective T cells. Our data suggest that instead of boosting Th1 and IFN- $\gamma$ , supplementing BCG with T<sub>CM</sub> that are insufficiently induced by BCG may be a feasible avenue towards TB vaccines that efficiently protect the TB infected lung. The data from animal models will be compared to the immune profile obtained with the H1/H56 vaccine in ongoing clinical trials.

## **THE ROLE OF THIOLS IN PROTECTION AGAINST OXIDATIVE STRESS IN MYCOBACTERIA**

*M. Rawat<sup>1</sup>, J. Thomas<sup>1</sup>, A. Rajkarnikar Singh<sup>1</sup>*

<sup>1</sup>Biology, California State University Fresno, Fresno, USA

### **Background**

Low molecular weight thiols maintain the reducing environment in cells and are responsible for protecting cells against oxidants and toxins. In mycobacteria such as *Mycobacterium tuberculosis*, the major low molecular weight thiol is mycothiol (MSH), which has similar protective functions as glutathione (GSH), the LMW thiol present in eukaryotes and gram-negative bacteria. Other LMW thiols present in mycobacteria include ergothioneine (ESH), whose sulfur atom is most stable in solution in the thione form, and thioredoxins, small redox proteins containing a dithiol-disulfide active site. The relative contributions of these LMW thiols in protecting mycobacteria against oxidative stress is not clear.

### **Objectives**

The objective of the study was to characterize the mutants to evaluate their role in oxidative stress defense.

### **Methods**

*Mycobacterium smegmatis* mutants lacking MSH, ESH, and disrupted in thioredoxins and thiol peroxidases were evaluated for sensitivity to oxidative stress. Quantitative real-time PCR was also performed to determine the expression of the thiol associated genes. Also, the levels of thiols, protein carbonylation and lipid oxidation were determined for the mutants.

### **Conclusions**

A majority of the mutants were sensitive to oxidative stress and a significant increase in expression of genes involved in thiol biosynthesis and genes coding for thiol peroxidases occurred on oxidant exposure. Protein carbonylation and lipid oxidation levels were higher in MSH mutants as compared to mutants lacking ESH and thiol peroxidases. Our data suggests that MSH rather than ESH plays an important thiol in protection against oxidative stress and there is redundancy in protection against oxidative stress.

**DEVR DEPENDENT SYNCHRONIZATION OF MYCOBACTERIAL GROWTH AND  
ITS EFFECT ON MYCOBACTERIOPHAGE DEVELOPMENT**

P. Kirtania<sup>1</sup>, S.K. Das Gupta<sup>1</sup>

<sup>1</sup>Microbiology, Bose Institute, Kolkata, India

**Background**

Hypoxic conditions are known to induce a state of dormancy in mycobacterial species. To what extent phage growth is affected in mycobacterial cells exposed to hypoxia is not known.

**Objectives**

We attempted to investigate this by studying the growth properties of mycobacteriophage D29 in *Mycobacterium smegmatis* hosts exposed to hypoxia.

**Methods**

*M. smegmatis* cells were subjected to hypoxia either by limiting O<sub>2</sub> supply (Wayne Model) or by treatment with vitamin C, an O<sub>2</sub> scavenger. Treated cells were then infected with D29 and phage growth was monitored by plaque assays.

**Conclusions**

1. The results indicate that the phage grows poorly under hypoxia but its proliferation is enhanced during the recovery phase.
2. Hypoxia sensors DevR-DevS/DosT may have a role to play in the process as DevR deletion mutant did not support the observed increase in phage growth.
3. The growth properties of the *wt* and *devR* *M. smegmatis* strains were compared in presence and absence of O<sub>2</sub> and was observed that the growth of *wt* cells was retarded by hypoxic conditions but the *devR* strain was unaffected. So, DevR plays an active role in retarding the growth of Mycobacterial cells when they are exposed to hypoxia.
4. Following the return to normoxia the retarded cells were found to resume growth in synchrony.
5. Synchronous growth was found to benefit phage development because most of the cells were in the same metabolic state. D29 thus indirectly uses DevR-DevS signalling system to its own advantage when their hosts were exposed to hypoxia.

**MSMEG\_2433 OF MYCOBACTERIUM SMEGMATIS EXHIBITS BOTH DD-CARBOXYPEPTIDASE AND BETA-LACTAMASE ACTIVITIES**

*A. Ghosh<sup>1</sup>, A. Bansal<sup>1</sup>, D. Kar<sup>1</sup>, S. Mallick<sup>1</sup>, M. Dutta<sup>1</sup>*

<sup>1</sup>*Biotechnology, Indian Institute of Technology Kharagpur, Kharagpur, India*

**Background**

DD-carboxypeptidases (DD-CPases) are low-molecular mass (LMM) penicillin-binding proteins (PBPs), mainly involved in the peptidoglycan remodelling, but little is known about the DD-CPases of mycobacteria. In this study, a putative DD-CPase of *Mycobacterium smegmatis*, MSMEG\_2433 has been characterized.

**Objectives**

- \*Physiological characterization of the membrane bound form of MSMEG\_2433
- \*Biochemical characterization of the soluble form of MSMEG\_2433

**Methods**

The gene for the membrane-bound form of *MSMEG\_2433* was cloned and expressed in *E. coli* in its active form as revealed by its ability to bind to the Bocillin-FL (fluorescent penicillin). Interestingly, *in vivo* expression of MSMEG\_2433 could restore the cell-shape oddities of the septuple PBP mutant of *E. coli*, which was a prominent physiological character of DD-CPases. Moreover, expression of MSMEG\_2433 *in trans*, elevated the beta-lactam resistance in the PBP deletion mutants ( $\Delta dacAdacC$ ) of *E. coli* that strengthened its physiology as a DD-CPase. To confirm the biochemical reason behind such physiological behaviours, soluble form of MSMEG\_2433 (sMSMEG\_2433) was created, expressed and purified. In agreement to the observed physiological phenomena, the sMSMEG\_2433 exhibited the DD-CPase activity against artificial and peptidoglycan-mimetic DD-CPase substrate. The enzymatic analyses of MSMEG\_2433 revealed the efficient deacylation for beta-lactam substrates, which is unique for beta-lactamases. In addition, *in silico* molecular analyses predicted the presence of an active-site that favours DD-CPase activity of MSMEG\_2433 and an omega-loop like region that determines its beta-lactamase activity.

**Conclusions**

Based on the *in vitro*, *in vivo* and *in silico* studies we conclude that MSMEG\_2433 is a dual enzyme, possessing both DD-CPase and beta-lactamase activities.

**Unfolded protein transport across membranes: The Injectisome in Action**

T. Marlovits<sup>1</sup>

<sup>1</sup>*CSSB-Centre for Structural Systemsbiology,  
University Medical Center Hamburg Eppendorf, Hamburg, Germany*

We are focusing on two fundamental aspects in biology (1) assembly of multicomponent systems into functional nanomachines and (2) transport of proteins across membranes. Both are found in type three secretion systems (T3SS), which are required of bacterial secretion of proteins into the host that subvert the host antibacterial response in order to promote infection. These systems utilize a 3.5 MDa syringe-like, membrane embedded “injectisome” containing an ~800 Å long needle complex thought to cross multiple membranes to connect the intracellular compartments of the bacteria and the host. The striking resemblance of the injectisome to a bona fide syringe, revealed by electron microscopy has led to the hypothesis that bacterial proteins are secreted through the needle complex into the host. I will discuss how and where substrates are passed through the T3SS and across two membranes by visualizing injectisomes in action and in situ.

<sup>1</sup>*Laboratoire de Chimie Bactérienne, CNRS-Aix Marseille University, Marseille, France*

<sup>2</sup>*Centre de biochimie structurale, CNRS-INSERM, Montpellier, France*

Bacteria move over solid surfaces by so-called gliding motility, a process whereby the bacterium moves smoothly along its long axis in absence of extracellular organelles. Due to the small size of the bacterial cell the gliding mechanism has long remained enigmatic. In recent years, we identified the *Myxococcus xanthus* motility engine and showed that it localizes to discrete sites along the cell long axis. However, the exact propulsion mechanism remained undetermined. In this presentation, I will present the motility machinery and recent work combining genetics, biophysics and modeling that allowed us to elucidate the motility mechanism.

**BACTERIAL TWITCHING MOTILITY IS COORDINATED BY A TWO-DIMENSIONAL TUG-OF-WAR WITH DIRECTIONAL MEMORY**

C. Meel<sup>1</sup>

<sup>1</sup>*Theoretische Physik, Biocenter, Köln, Germany*

**Background**

Many bacterial species possess appendages that allow them to move while staying attached to the surface. One of the most ubiquitous cell appendages that mediate movement is the type IV pilus system.

Type IV pilus dependent movement has been known as 'twitching motility' for a long time, but only recently we were able to demonstrate experimentally that *Neisseria gonorrhoeae* moves with directional persistence and proposed that its multiple pili are coordinated through a tug-of-war mechanism. [1]

**Objectives**

We addressed the question whether the pilus dynamics was coordinated mechanically and thereby promoting persistent movement, a mechanism that has been shown to be efficient in other processes.

**Methods**

We used a combined theoretical and experimental approach to test this hypothesis. Using laser tweezers we measured detachment rates and pilus retraction speeds at the level of single pili. Using this quantitative data we build a tug-of-war model.

**Conclusions**

Unexpectedly, we found that the two-dimensional tug-of-war is less efficient in generating persistent motion than the one-dimensional tug-of-war studied previously in the context of cytoskeletal transport. [2] The systematic comparison of the patterns of motility with the corresponding experimental data showed that a form of directional memory is required to explain experimental observations. Experimentally, we confirmed memory in the form of bursts of pilus retraction.

Overall, type IV pili are essential for two opposing phenotypes in *N. gonorrhoeae*, namely motility and clustering into microcolonies and biofilms. Directional persistence is likely to bias the behaviour towards motility.

M. Ackland<sup>2</sup>, M. Kochar<sup>1</sup>

<sup>1</sup>TERI-Deakin NanoBiotechnology Centre, The Energy and Resources Institute,  
New Delhi, India

<sup>2</sup>Centre for Cellular & Molecular Biology, Deakin University, Melbourne, Australia

<sup>3</sup>Institute for Frontier Materials, Deakin University, Geelong, Australia

**Background**

Microorganisms are known to produce extracellular, proteinaceous nanofilaments called type IV pili (TFP) which are known to be involved in different functions like twitching motility, adhesion, biofilm formation etc.. These TFP from *Geobacter sulfurreducens* were found to be electrically conductive and termed as microbial nanowires.

**Objectives**

As early studies on microbial nanowires focussed on anaerobic microorganisms, this study was undertaken to identify, optimize and structurally characterize microbial nanowires in *Microcystis aeruginosa*.

**Methods**

For electrical characterization, conductive atomic force microscopy (CAFM) was used while for structural characterization, transmission electron microscopy (TEM) and *in-silico* methods were employed. For optimal production of pili, cells were subjected to different stressful culture conditions i.e. carbon source limitation and high light intensity and their piliation level were qualitatively checked using TEM.

**Conclusions**

TFP in *M. aeruginosa* was observed to be 8.5-11nm in diameter and 2μ to several μ long. They seem to be either composed of two distinct subfilaments or may be hollow cylinders. The piliation level in *M. aeruginosa* was sensitive to the culture conditions used. CAFM study showed that TFP in *M. aeruginosa* are electrically conductive in nature and can act as a microbial nanowire. *in-silico* studies suggested that aromatic amino acids may be involved in electron transfer through these TFP. The role of such nanowires in toxic bloom formation needs to be investigated further. This study significantly increases our understanding about aerobic cyanobacterial nanowires and also gives impetus for further research in this field and potential environmental applications.

**THE BACTERIAL FLAGELLUM OF SALMONELLA: PROTEIN EXPORT MECHANISMS OF A MACROMOLECULAR MACHINE**

*F.D. Fabiani<sup>1</sup>, M.E. Mertens<sup>2</sup>, K.T. Hughes<sup>2</sup>, D.F. Blair<sup>2</sup>, M. Erhardt<sup>1</sup>*

*<sup>1</sup>Young Investigator Group Infection Biology of Salmonella, Helmholtz Centre for Infection Research, Braunschweig, Germany*

*<sup>2</sup>Department of Biology, University of Utah, Salt Lake City, USA*

**Background**

*Salmonella* swims through liquid environments by rotating a helical organelle, the flagellum. This flagellum is closely related to virulence-associated injectisome systems. A type-III protein secretion (T3S) apparatus is utilized to secrete building blocks of the flagellum, structural subunits of the injectisome complex, as well as virulence effectors into host cells.

**Objectives**

The T3S apparatus utilizes both the energy of the proton motive force (PMF) and ATP hydrolysis to energize substrate unfolding and translocation. However, the role of the T3S ATPase and other export apparatus components remained unclear.

**Methods**

We used bacterial genetics, fluorescent microscopy and reporter secretion assays to probe the function of the T3S apparatus *in vivo*.

**Conclusions**

We report formation of flagella in the absence of T3S ATPase activity by mutations that increased the PMF and flagellar substrate levels. We additionally show that increased PMF bypassed the requirement of the Spi1 virulence-associated T3S ATPase for secretion. We thus demonstrate that the actual export process is energized by the means of the proton motive force and does not require ATP hydrolysis.

Finally, we performed a genetic screen to dissect the minimally essential components of the flagellar T3S apparatus. We show that most integral-membrane components are essential and all cytoplasmic components are dispensable for export, emphasizing the importance of the core inner-membrane export apparatus components for the function of type-III secretion systems.

In summary, our data support a role for T3S ATPases in enhancing secretion efficiency under limited secretion substrate concentrations and reveal the essential core components of the T3S apparatus.

#### **THE STRUCTURE OF THE TYPE SIX SECRETION SYSTEM CONTRACTILE SHEATH SOLVED BY CRYO ELECTRON MICROSCOPY**

M. Brackmann<sup>1</sup>, M. Kudryashev<sup>1</sup>, R. Wang<sup>2</sup>, S. Scherer<sup>1</sup>, T. Maier<sup>1</sup>, D. Baker<sup>2</sup>, F. DiMaio<sup>2</sup>, H. Stahlberg<sup>1</sup>, E. Egelman<sup>3</sup>, M. Basler<sup>1</sup>

<sup>1</sup>Biozentrum, University of Basel, Basel, Switzerland

<sup>2</sup>Department of Biochemistry, University of Washington, Seattle, USA

<sup>3</sup>Department of Biochemistry and Molecular Genetics, University of Virginia, Charlottesville, USA

#### **Background**

Bacteria use rapid contraction of a long sheath of the Type VI secretion system to deliver effectors into a target cell.

#### **Objectives**

The mechanism of contraction is still unclear, mostly due to a lack of a high-resolution structure of the sheath.

#### **Methods**

We used cryo-electron microscopy and helical reconstruction to solve an atomic resolution structure of a native *Vibrio cholerae* sheath. Fluorescence microscopy and bacterial competition assays confirm central findings.

#### **Conclusions**

The localization of the outer domain of the sheath facilitates unfolding by ClpV. Structural alignments with phage sheaths indicate a conserved mechanism of interaction. In the innermost layer, a 4-stranded  $\beta$ -sheet from three proteins links the protomers in the same strand as well as neighboring strands. This  $\beta$ -sheet is crucial for polymerization and stability.

**FEMS-2552**

## **Syntrophic interactions in anaerobic communities**

### **New insights in syntrophy in methanogenic communities**

C.M. Plugge<sup>1</sup>

<sup>1</sup>Laboratory of Microbiology, Wageningen University, Wageningen, Netherlands

### **New insights in syntrophy in methanogenic communities**

In methanogenic environments, syntrophic communities form the core of the organic acid degrading population. Organic acids are only efficiently converted if the syntrophs maintain a close relationship, driven by interspecies electron transfer. The eco-physiology of syntrophs is poorly understood as only a few syntrophs have been thoroughly characterized. To clarify their eco-physiology, it is important to study syntrophs *in situ* but also understand the biochemical mechanisms they have to adapt their metabolism to changing environmental conditions.

Based on genome analysis of our model syntrophic propionate-degrading community *Syntrophobacter fumaroxidans* and *Methanospirillum hungatei* and expression of genes involved in interspecies electron transfer we revealed mechanisms that enable the coculture to adapt<sup>1</sup>.

Single-cell microbiology enables microbiologists to observe who does what, when, where and next to whom<sup>2</sup>. Single cells taken from the environment can be identified and their genome sequenced. Single-cell based gene expression analysis could be a valuable tool in interpreting gene functions and microbial metabolism in various syntrophic communities and reveal genes and gene clusters that are involved in syntrophy<sup>3</sup>.

This presentation will discuss syntrophy and methanogenic syntrophic communities and emphasize on recent developments and discoveries.

**Microbial collaboration for effective electron transfer**

Research on extracellular electron transfer has accelerated in the past ten years. Whereas the process itself was described in 1986, only in the 2000s major interest emerged leading to the discovery of direct electron transfer to and from electrodes, and more recently the discovery that pili or pilus-like appendages are involved in long range electron transfer. The electrical interactions are not only occurring between a microorganism and an electrode or mineral, it is now clear that microorganisms interact among each other via electrons. It is likely that they do so to link their overall respiration, settling charge balances via solid state transfer rather than relying on diffusive processes. Taking this information on board, earlier findings on the microbial ecology of electroactive biofilms make more sense and it appears that in anaerobic environments the physiology related to electron transfer needs to be included when considering aspects such as syntrophic interactions. In my presentation, I will give an overview of the findings by many researchers worldwide, and try to assess how this impacts particular applications such as microbial electrosynthesis, microbial electrochemical systems and anaerobic digestion processes.

<sup>2</sup>Microbiology, Wageningen University, Wageningen, Netherlands

<sup>3</sup>Irstea, UR HBAN, Antony Cede, France

**Background**

Conversion of long-chain fatty acids (LCFA) in anaerobic digesters relies on syntrophic relationship between acetogenic bacteria and methanogenic archaea. Conversion of unsaturated- and saturated-LCFA has been previously shown by a co-culture of *Syntrophomonas zehnderi* and *Methanobacterium formicum*. Degradation of unsaturated-LCFA is rare among *Syntrophomonas* species; the best studied fatty-acid oxidizer, *S. wolfei*, can only grow on saturated-LCFA.

**Objectives**

Major differences are expected in the pathways and enzymes involved in the degradation of unsaturated-LCFA. In this work we used proteogenomic approach to study these differences.

**Methods**

A draft genome of *S. zehnderi* was obtained by IlluminaHiSeq sequencing. Genomes of *S. zehnderi* and *S. wolfei* (available at NCBI) were compared. *S. zehnderi* and *M. formicum* co-cultures grown on oleate (unsaturated LCFA, C18:1) and on stearate (saturated LCFA, C18:0) were further studied using a proteomics approach.

**Conclusions**

Genomic comparison of *S. zehnderi* and *S. wolfei* revealed approximately 900 different proteins and 1200 common proteins. In the genome of *S. zehnderi*, two replicates of the unsaturated acyl-CoA dehydrogenase genes were identified, one of which differs considerably from the acyl-CoA gene found in *S. wolfei*. Proteomic analysis of *S. zehnderi* and *M. formicum* co-cultures revealed high expression levels of proteins related to the  $\beta$ -oxidation of LCFA (up to 30% of total proteins identified). Different protein expression levels were observed during the degradation of oleate (44% unique proteins) and stearate (23% unique proteins). In addition, proteins involved in electron transfer were highly expressed, including electron transfer flavoproteins, ATP synthases and a number of hydrogenases and formate dehydrogenases.

**SYNTROPHIC COCULTURE OF GEOBACTER SULFURREDUCTENS AND  
SYNTROPHOBACTER FUMAROXYDANS GROWING WITH PROPIONATE AND  
Fe(III)**

M. Mollae<sup>1,2</sup>, A.J.M. Stams<sup>1</sup>, C.M. Plugge<sup>1,2</sup>

<sup>1</sup>Laboratory of Microbiology, Wageningen University, Wageningen, Netherlands

<sup>2</sup>Wetsus, Centre of Excellence for Sustainable Water Technology, Leeuwarden, Netherlands

**Background**

The Fe(III)-reducing *G. sulfurreducens* is restricted to simple organic substrates like acetate as the electron donor and unable to metabolise propionate. *S. fumaroxidans* on the other hand cannot use Fe(III) as electron acceptor.

**Objectives**

Syntrophic coculture of the electroactive bacterium *Geobacter sulfurreducens* and the propionate oxidising bacterium *Syntrophobacter fumaroxidans* with propionate and Fe(III) were constructed.

**Methods**

*G. sulfurreducens* was first grown in pure culture with single and different combinations of the electron donors of acetate, formate and hydrogen as the products of propionate oxidation by *S. fumaroxidans*. All single electron donors supported the growth of *G. sulfurreducens* where  $6.44 \pm 0.02$ ,  $2.43 \pm 0.01$  and  $1.63 \pm 0.41$  mole of Fe(II) was produced per mole of acetate, formate and hydrogen, respectively. When different combination of electron donors applied, no acetate consumption was noted in the presence of formate. Moreover, in the presence of hydrogen, reduced amount of acetate/formate was needed for Fe(III) reduction compared with similar conditions without hydrogen. Next, our coculture results showed for the first time the successful growth of these two bacteria with propionate and Fe(III) in batch cultures, where neither of bacteria was independently capable of such growth.

**Conclusions**

The exceptionally high ratio of Fe(II) production per propionate consumption ( $17.3 \pm 2.52$ ) showed high potential of the applied coculture for iron reduction using propionate as the electron donor. Further molecular and microscopic studies are underway to illustrate the spatial structure of the coculture and the abundance of the two partner bacteria.

## **Syntrophic interactions in anaerobic communities**

### **SYNTROPHIC ETHANOL OXIDATION - A LONG WAY TO A CONVINCING SOLUTION**

B. Schink<sup>1</sup>, N. Mueller<sup>1</sup>, A. Schmidt<sup>1</sup>

<sup>1</sup>Biology, Biology, Konstanz, Germany

#### **Background**

Methanogenic conversion of ethanol to acetate plus methane has been described by Wolin et al. in 1967 as the first case of syntrophic cooperation between two species in methanogenic degradation. In the co-culture "*Methanobacillus omelianskii*", the so-called S-organism cooperated with a hydrogen-oxidizing methanogen. The oxidation pathway as conceptualized with this culture included alcohol dehydrogenase, acetylating acetaldehyde dehydrogenase, and subsequent ATP formation via phosphotransacetylase and acetate kinase. This concept has been confirmed later with *Pelobacter acetylenicus* and other *Pelobacter* species .

#### **Objectives**

*Pelobacter spp.* have to invest part of their ATP gain into a reversed electron transport to release electrons as hydrogen or formate. The overall energy balance leaves less than one ATP per reaction run for these bacteria. We wanted to elucidate the mechanism of electron flow from ethanol to hydrogen.

#### **Methods**

Studies included enzyme assays in cell-free extracts as well as genomic and proteomic analyses.

#### **Conclusions**

Genomic studies indicated that *Pelobacter carbinolicus* contains a comproportionating hydrogenase oxidizing NADH and ferredoxin simultaneously. Methanogenic ethanol-oxidizing cocultures maintained formate and hydrogen levels equivalent to a standard redox potential of  $E^0 = -360$  mV. Combined with further genomic information, our results provide a convincing concept for electron flow and ATP synthesis in syntrophically ethanol-oxidizing *Pelobacter* species.

**MICROBIAL SYSTEMS ECOLOGY: FROM DEFINING NICHES TO  
RECONSTRUCTING MATTER FLOWS THROUGH MICROBIAL CONSORTIA**

P. Wilmes<sup>1</sup>, E. Muller<sup>1</sup>, S. Narayanasamy<sup>1</sup>, M. Herold<sup>1</sup>, A. Sheik<sup>1</sup>, C. Laczny<sup>1</sup>,  
A. Heintz-Buschart<sup>1</sup>

<sup>1</sup>Luxembourg Centre for Systems Biomedicine, University of Luxembourg, Esch-Sur-Alzette, Luxembourg

**Background**

Mixed microbial communities are complex and dynamic systems. Integrated omics (combined metagenomics, metatranscriptomics, metaproteomics and metabolomics) are currently gaining momentum for detailed descriptions of community structure, function and dynamics *in situ*. These top-down analyses also allow inference of fundamental ecological properties of constituent populations and allow a description of the flow of matter through these systems.

**Objectives**

To define niche breadths of constituent populations and to infer the flow of matter through a mixed microbial community from integrated omics data.

**Methods**

We have developed an integrative workflow comprising wet- and dry-lab methodologies that enables systematic measurements of microbial communities, and the integration and analysis of the resulting “multi-meta-omic” data including in the context of reconstructed metabolic networks. Here we apply this methodological framework to our model microbial communities (lipid accumulating microbial consortia from a biological wastewater treatment tank) sampled over space and time.

**Conclusions**

By resolving multi-omic data at the population-level, we are able to infer lifestyle strategies (generalists versus specialists) of the respective constituent populations. More specifically, through our analyses, we have uncovered patterns which suggest that, under rapidly fluctuating environmental conditions, the dominance of a microbial generalist is linked to finely tuned resource usage, and that genetic variation within generalist populations is constrained. Furthermore, by reconstructing population-resolved metabolic networks and interfacing there, we are able to partially reconstruct the flow of matter through the community. These results bring us closer to being able

to infer key ecological characteristics of constituent microbial populations as well as matter and ultimately energy flows through communities.

### **Secretion in Bacteria**

#### **Mechanisms of Bacterial Secretion**

G. Waksman<sup>1</sup>

<sup>1</sup>*Institute of Structural and Molecular Biology, UCL and Birkbeck, London, United Kingdom*

#### **Mechanisms of Bacterial Secretion**

**Gabriel Waksman**<sup>1</sup>

<sup>1</sup> Institute of Structural and Molecular Biology at UCL and Birkbeck, Malet Street, London, WC1E 7HX, UK

Type IV secretion (T4S) systems are molecular machines used for the transport of macromolecules across the bacterial cell envelope. T4S systems are highly versatile. Conjugative T4S systems translocate DNA from a donor to a recipient bacterium and contribute to bacterial genome plasticity, spread of antibiotic resistance or other virulence trait among bacterial pathogens. In some bacteria such as *Helicobacter pylori* (Cag PI), *Brucella suis* (VirB/D), or *Legionella pneumophila* (Dot, Icm), T4S systems are directly involved in pathogenicity as they mediate the secretion of virulence factors (DNA or toxins) into host cells. The archetypal T4S system, the VirB/D system, was defined in *Agrobacterium tumefaciens* where it is naturally responsible for the delivery of the T-DNA to the plant host-cell. The *A. tumefaciens* VirB/D system comprises 12 proteins (VirB1 to 11 and VirD4). Recently, structures of large complexes formed by several of these proteins have become available shedding unprecedented light on T4S system secretion mechanism.

### **Microbial responses to illumination**

#### **On the role of photosensory receptors in (chemo) trophic bacteria**

K. Hellingwerf<sup>1</sup>

<sup>1</sup>*Molecular Microbial Physiology, Swammerdam Institute for Life Sciences, Amsterdam, Netherlands*

Oxygenic photosynthesis and its applications in (energy) biotechnology will have to have a key role in a sustainable future. It is therefore significant that this process can be straightforwardly engineered in oxygenic phototrophic organisms, such as cyanobacteria, using the tools of synthetic biology. This has led to the emergence of cell factories that catalyze the (sun)light-driven conversion of CO<sub>2</sub> and water into products like ethanol, butanol, or other bio-fuels, commodity chemicals like lactic acid, a bio-plastic precursor, and even artificial sweeteners and flavor compounds. Only oxygen is produced as a by-product. For successful application of this approach it is of key importance to optimize such cell factories to maximal efficiency. This holds for their light-harvesting capabilities, e.g. under circadian illumination in large-scale photo-bioreactors, but equally well for the 'dark' reactions of photosynthesis, i.e. the conversion of CO<sub>2</sub>, NADPH and ATP into a (biofuel) product.

After an introduction of the versatility of this approach, an analysis based on metabolic control theory is presented of the amount of the enzymes catalyzing the heterologous metabolic pathway for product formation with which such cyanobacterial cell factories have to be equipped for maximal rates of product formation. For this engineered L-lactic acid producing *Synechocystis* sp. PCC6803 strains are used to identify the relation between actual production rate and expressed enzyme capacity. The analysis shows that engineered cell factories (e.g. for L-lactic acid) require high capacity of the heterologous product-forming pathway, before control in other parts of the cell factory can be detected and relief of limitation in those other parts becomes relevant.

**Microbial responses to illumination**

**Photoprotection in cyanobacteria and the photoactive Orange Carotenoid Protein**

D. Kirilovsky<sup>1</sup>

<sup>1</sup>I2BC, CNRS-CEA, Gif sur-Yvette, France

The water-soluble orange carotenoid protein (OCP), a cyanobacterial protein of 35kDa which binds a single keto-carotenoid was first described and isolated by Holt and Krogman in 1981. During long time its role was unknown. In 2006 we demonstrated that OCP is essential in photoprotection in cyanobacteria. Cyanobacteria protect themselves from intense sunlight by dissipating excess absorbed energy as heat at the level of their extramembranal antenna, the phycobilisomes. This decreases the formation of dangerous species of oxygen and diminishes photodamage. The process is induced by the absorbance of blue-green light by the OCP, which acts as the light intensity sensor and the excitation energy quencher and is a new member of the family of photoactive proteins. It is the first photoactive protein containing a carotenoid as the photoactive chromophore and its photocycle is completely different from those of other photoactive proteins. The absorbance of blue-green light by the OCP induces structural changes in the carotenoid and the protein, converting its dark stable orange form (OCP<sup>o</sup>) into a relatively unstable active red form (OCP<sup>r</sup>). OCP<sup>r</sup> form is essential for the induction of the photoprotective mechanism. Only OCP<sup>r</sup> is able to interact with phycobilisomes and to quench excess energy. A second protein, the Fluorescence Recovery Protein, is needed to detach the OCP<sup>r</sup> from phycobilisomes and converted to the inactive OCP<sup>o</sup> form. All the known details of this mechanism will be described in the conference. We have recently demonstrated that OCP has another essential role in the cells: it's a very good singlet oxygen quencher. Thus, OCP has dual and complementary photoprotective action as energy quencher and as singlet oxygen quencher.

**Microbial responses to illumination**

**Signaling by Phytochrome, A Knotted Bacterial Photoreceptor**

K.T. Forest<sup>1</sup>, A.W. Baker<sup>1</sup>, S. Bhattacharya<sup>1</sup>

<sup>1</sup>Bacteriology, University of Wisconsin-Madison, Madison WI, USA

Phytochrome is a multidomain red-light photoreceptor that allows cells to respond to the quality and intensity of incoming light. Bacterial phytochromes adopt a deep figure-of-eight knotted polypeptide. They bind the linear tetrapyrrole biliverdin covalently via a thioether link to cysteine. Photon absorption causes a rotation about the C15=C16 double bond of this chromophore, leading to signaling through the conserved PHY domain to a modular output domain. To advance our research goals of understanding the structure/function relationships of bacterial phytochromes, we are studying the biochemistry and structural biology of the signal transduction pathway of the bacterial phytochromes of *Deinococcus radiodurans* and *Ramlibacter tatouinensis*. Each contains a histidine kinase domain, and each is predicted to be a light-regulated enzyme that phosphorylates across a homodimeric interface and subsequently transfers phosphate to a response regulator protein. We have established a robust *in vitro* kinase assay and have shown that *R. tatouinensis* bacterial phytochrome is an autokinase that interacts specifically with at least one cognate single domain response regulator (Brr). Kinase activity is markedly lower under red light. We have also refined the X-ray crystal structure of the Brr protein. A C-terminal extension of the canonical response regulator fold creates a unique dimer interface not seen outside the phytochrome-associated response regulators. We are engaged in determining the functional consequences of the knotted phytochrome topology and the oligomeric response regulator. We imagine both could limit motions of phytochrome domains upon illumination to steer signal transduction along a productive trajectory.

**The human virome: new tools and concepts**

**Increasing the knowledge of the human virome at homeostasis and disease by deep sequencing of clinical samples**

M. Eloit<sup>1</sup>

<sup>1</sup>*Virology, Institut Pasteur, Paris, France*

The composition, interindividual and temporal variability of the human virome are not precisely known but new questions arise in the context of the rapidly increasing knowledge regarding its composition and function. Its impact on human health has received less attention than that of the bacterial microbiome, but is likely to be as important, both in homeostasis and disease. In fact, it is increasingly apparent that viral pathogens are only the salient members of a larger group of viruses associated with humans that are not directly linked to disease, analogous to the bacterial component of the microbiome. In particular, viruses abound at the body interfaces with the external environment, on the skin and in the mucosa. In contrast to this, the presence of viruses in the blood and organ parenchyma of healthy people is rather the exception than the rule, although a limited number of viral species establish persistent, albeit mostly silent, systemic infections, more often in immunocompromised individuals. With the ever-extending use of next generation, rapid progress on its impact on human health is to be expected in the coming years including the identification of viruses with roles in chronic diseases. We will show how deep sequencing of human clinical cases samples reveals, rather than new viral species, an unexpected role of known viruses in human diseases particularly in immunocompromised patients. On the other hand, whilst cross transmission from animals is preeminent in emerging viral diseases, close or identical new viral species are found in human and animals at homeostasis, which suggests more circulation between species than anticipated.

### **The human virome: new tools and concepts**

#### **How to study phages in natural communities: tools, concepts and challenges**

M.B. Sullivan<sup>1</sup>

<sup>1</sup>*Microbiology, Ohio State University, Columbus, USA*

Microbes drive the biogeochemical cycles that fuel the planet, and their viruses play important roles ranging from mortality and nutrient cycling to gene transfer in environments ranging from the oceans and soils to industrial fermenters and humans. However, our inability to “see” viruses in the environment challenges our broader and quantitative understanding of viral roles in ecosystem processes. My lab specializes in developing new experimental and informatic approaches to better “see” and interpret the diversity of wild viruses across myriad data types and environments. Together these methods link viruses to their hosts *en masse*, provide both single-cell and population perspectives on virus-host interactions, or help elucidate Viral Dark Matter that dominates surveys of viruses in nature. In natural communities, we have mapped much of the global virome, shown that viral genome sequence space is clustered (into ‘populations’ formally delineated as species), and provided hypotheses on the role of viral metabolic reprogramming in modulating ecosystem function. This ability to now ‘count’ biologically meaningful units for viruses in nature – both genes and ‘organisms’ – opens watershed possibilities for applying ecological and evolutionary theory and developing predictive modeling across diverse ecosystems. Beyond the oceans, microbes are emerging as major players in terrestrial and atmospheric biogeochemical and energy cycling, as well as many diseases humans. Viral roles in modulating these microbial impacts are virtually unstudied, but likely to be large. To this end, my lab is now optimizing and applying these novel ocean-derived experimental and ‘big data’ analytical approaches to viral communities across diverse environments including sediments, the human lung and gut, and climate-sensitive thawing permafrosts, with aspirations to explore roles of viruses in the atmosphere and the Built Environment.

**The human virome: new tools and concepts**

**Human and animal viruses identified through metagenomics: pathogens, commensals, or contaminants?**

E. Delwart<sup>1</sup>

<sup>1</sup>*BSRI, UCSF, San Francisco, USA*

Viral metagenomics is the unbiased amplification and sequencing of viral particles-associated nucleic acids and their classification using sequence similarity to known viruses. The research and diagnostic opportunities provided by this approach include the development of universal and sensitive virus identification tools and viral pathogen discovery. Our methodology and bioinformatics pipeline, together with their limitations, will be briefly described. Examples of virus and viral DNA contamination and the detection within mammalian samples of viral sequences originating from diverse cellular hosts will be shown. New viral genomes from human and animal samples with unexplained diseases of suspected infectious origins will be described together with the exp performed or required to demonstrate their pathogenicity. Some of these newly described viruses are highly prevalent, particularly in infants from developing countries, both sick and healthy, with frequent co-infections. The rapid rate of viral discovery provides many opportunities for epidemiological and in vivo studies to explore the role of these “new” viruses in both health and disease.

**Why we need to worry about bacterial infections?**

**Collaborating with the innate immune system to combat multidrug-resistant bacterial pathogens**

V. Nizet<sup>1</sup>

<sup>1</sup>Center for Immunity Infection and Inflammation,  
University of California San Diego School of Medicine, La Jolla CA, USA

Antibiotic resistance presents an ever increasing challenge to the public health with a dearth of new drugs in the development pipeline. Conventional screening paradigms in antibiotic discovery are based on MIC/MBC testing in conventional bacteriologic media, and similar tests on patient isolates are used to guide physician management. Economic factors have favored development of broad spectrum agents, which exert "collateral damage" on the normal microflora, now increasingly recognized to have adverse health consequences. A single-minded focus on direct antimicrobial activities overlooks the fact that significant infections are really a disease of the host-pathogen interaction. Indeed, before the patient has even seen a doctor, their infection is already being treated by multiple antimicrobials - namely the cellular and molecular components of the innate immune system. We see value in exploring potential novel therapeutic approaches for drug-resistant bacteria that aim to tip the host-pathogen interaction back in favor of the host. This talk will illustrate three such classes of novel therapeutics: (A) Inhibitors of bacterial virulence factors that re-sensitize the pathogen to innate immune killing; (B) Drugs that directly boost the antibacterial killing capacity of host phagocytic cells; (C) Antibiotics that synergies with endogenous antimicrobial peptides to effect bacterial killing. These studies will reveal how standard MIC testing can be misleading, and overlook potent antibiotic activities that are recognized only the context of the normal innate immune system. In this new discovery and treatment framework, drugs used in medicine for other indications, or antibiotics otherwise deemed ineffective, can be "repositioned" for treatment of multi-drug resistant pathogens such as methicillin-resistant *Staphylococcus aureus* (MRSA), vancomycin-resistant *Enterococcus* spp. (VRE) or carbapenemase-resistant strains of Gram-negative pathogens including *Acinetobacter baumannii*, *Klebsiella pneumoniae* and *Pseudomonas aeruginosa*.

**Why we need to worry about bacterial infections?**

**Meningococemia a disease of the endothelial cells**

X. Nassif<sup>1</sup>

<sup>1</sup>*Department of Microbiology, Institut Necker-Enfants Malades, Paris, France*

*Neisseria meningitidis*, (also known as the meningococcus), is a common inhabitant of the human nasopharynx, and as such is a normal, saprophytic organism that is transmitted from person to person. These bacteria can therefore spread in a population by direct contact. Paradoxically, in a small proportion of colonized subjects, they disseminate from the nasopharynx into the bloodstream, leading to clinical features, which are rarely observed in bacterial septicemia. First, meningococci usually cross the blood brain barrier, invade the meninges and cause meningitis. Secondly meningococemia is usually associated with a thrombotic syndrome, which causes limited skin purpuric lesions, in addition to the meningeal inflammation in its milder form, or extensive thrombosis and necrotic purpura associated with massive vascular leakage and shock, known as *purpura fulminans*, in its more severe form. The epidemic nature of meningococcal transmission and the high mortality rate, especially in case of *purpura fulminans*, are responsible for the fear of meningococcal infections in communities. *In vivo* observations have clearly shown that *Neisseria meningitidis*, once in the bloodstream, interact closely with the microvessels. This interaction is mediated by the type IV pili. The mechanisms and consequences of this interaction will be analyzed in the light of the clinical consequences.

## FEMS-2402

### Why we need to worry about bacterial infections?

#### Buruli ulcer: from disease to pain control

P. Brodin<sup>1</sup>, O. Song<sup>1</sup>, E. Marion<sup>2</sup>, Y. Comoglio<sup>3</sup>, G. Sandoz<sup>3</sup>, L. Marsollier<sup>2</sup>

<sup>1</sup>Institut Pasteur of Lille, Inserm, Lille, France

<sup>2</sup>CHU Angers, Inserm, Angers, France

<sup>3</sup>University of Nice, CNRS, Nice, France

Buruli ulcer is an infectious disease transmitted by arthropod vectors harboring *Mycobacterium ulcerans*, a mycobacterium which belongs to the same family of bacteria causing tuberculosis and leprosy. The infection causes painless swelling and severe skin lesions. One key feature of *M. ulcerans* bacterium is its ability to secrete a necrotic toxin, the mycolactone within small lipophilic vesicles, which are critical for the bacterial induced pathogenicity. The biological knowledge as well as the preventive and therapeutic means for this invalidating disease is still very limited.

The extensive skin lesions, despite their severity, are not accompanied by pain. It was previously thought that this remarkable analgesia is ensured by direct nerve cell destruction. We demonstrate that *M. ulcerans*-induced hypoesthesia is instead achieved through a specific neurological pathway triggered by the secreted mycobacterial polyketide mycolactone, leading to potassium-dependent hyperpolarization of neurons. By use of a combination of siRNA and chemical library image based screening, we showed that mycolactone elicits signaling through type 2 angiotensin II receptors (AT2Rs) leading to the activation of cyclooxygenase I and TRAAK potassium channels, which causes neuron desensitization. We further validate the physiological relevance of this mechanism with in vivo studies of pain sensitivity in mice infected with *M. ulcerans*, following the disruption of the identified pathway. Our findings shed new light on molecular mechanisms evolved by natural systems for the induction of very effective analgesia, opening up the prospect of new families of analgesics derived from such systems.

**FEMS-2866**

**Why we need to worry about bacterial infections?**

**The use of antibiotics drive the evolution of resistance by activating competence for DNA uptake: Molecular mechanisms involved in *Streptococcus pneumoniae***

J.W. Veening<sup>1</sup>

<sup>1</sup>*Molecular Genetics, University of Groningen, Groningen, Netherlands*

The rapid spread of antibiotic resistance, combined with a near absence of new antibiotics, are leading to a public health threat. One of the leading bacterial causes of morbidity and mortality worldwide is *Streptococcus pneumoniae* (the pneumococcus). Frighteningly, inappropriate antibiotic treatments can accelerate the occurrence of multidrug resistance by activation of a developmental process called bacterial competence.

In this presentation I will discuss how antibiotics affects pneumococcal physiology and how antibiotics promote competence development. Molecular insights into the mechanisms driving bacterial evolution and resistance will advance the quest for novel treatment strategies.

**FEMS-3164**

**Bacterial predators**

***Bdellovibrio bacteriovorus*- biology of invasive bacterial predation**

R.E. Sockett<sup>1</sup>

<sup>1</sup>*Life Sciences, University of Nottingham, Nottingham, United Kingdom*

*Bdellovibrio bacteriovorus* is a predatory delta-proteobacterium, with a 3.8Mb genome inside a vibroid cell only 1µm x 0.3µm.

Locomotion by a single flagellum or by a gliding apparatus delivers *Bdellovibrio* to encounter other Gram-negative cells at their outer membrane. There is an attachment (via the non-flagellar pole) and recognition phase and then invasion by *Bdellovibrio* and intraperiplasmic growth, inside the, now-dead, but intact, prey. Growth in the periplasm requires modification of the prey cell wall to prevent premature lysis as the predatory life history strategy of *Bdellovibrio bacteriovorus* is not to share nutrients with bacteria outside the prey. The nutrients available from the prey are finite and dependent on cell volume and even or odd numbers of *Bdellovibrio* progeny are produced. *Bdellovibrio* motility resumes at the end of predator replication to escape the exhausted prey cell by flagellar or gliding motility. The non flagellar pole is specialised for prey-interaction and this involves Type IV pili and associated regulatory proteins, functions for which are becoming understood. This presentation will review the prey-modification and predatory growth processes of *B. bacteriovorus* and touch on their evolution.

**FEMS-0602**

**Bacterial predators**

**When cheese gets the flue: how dairy lactic acid bacteria succumb to bacteriophage attack**

D. van Sinderen<sup>1</sup>

<sup>1</sup>*Microbiology, University College Cork, Cork, Ireland*

Bacteriophages are a constant threat to commercial dairy plants, where their presence may lead to inconsistent, delayed or even disrupted fermentations. Over the last 50 years bacteriophages infecting lactic acid bacteria, and in particular dairy strains of *Lactococcus lactis*, have been isolated and studied to learn about their diversity and biology, as well as to find ways by which their negative impact on their host can be reduced or managed. In recent years, a wealth of information has been generated related to lactococcal host recognition by phages with (non-contractile) tails, representing the vast majority of (dairy-associated) phages. This presentation will present data on recent work in this field, highlighting the role of the saccharide-recognizing base plate located at the tip of the lactococcal phage tail, while also discussing the (diversity of the) phospho-polysaccharide receptor, which is recognized by the base plate.

**FEMS-0600**

**Bacterial predators**

**Structural Biology as a Tool to Study Predatory Bacteria**

A. Lovering<sup>1</sup>, I.T. Cadby<sup>1</sup>, R. Meek<sup>1</sup>, R.E. Sockett<sup>2</sup>

<sup>1</sup>*Institute of Microbiology & Infection School of Biosciences, University of Birmingham, Birmingham, United Kingdom*

<sup>2</sup>*School of Genetics, University of Nottingham, Nottingham, United Kingdom*

*Bdellovibrio bacteriovorus* is a predatory bacterium that enters other Gram negatives, residing in their periplasm and killing them from within. The goal of my lab is to understand this process on the molecular level, detailing how predation-specific proteins function by use of structural biology. We are currently investigating cell wall metabolism (entry into prey), cyclic-di-GMP signalling (control of predation events), host-independence (conversion to a form that can grow/replicate outside of the prey cell) and a variety of cryptic genes (*Bdellovibrio* has many unique genes, forming the “predatosome”). This presentation will provide examples of our progress in these areas and what we can learn about the toolkit required to live a predatory lifestyle.

**FEMS-2521**

**Bacterial predators**

***Pseudomonas* Predators: A systems' biology perspective of the phage infection process**

R. Lavigne<sup>1</sup>

<sup>1</sup>*Biosystems - Laboratory of Gene Technology, KU Leuven, Leuven, Belgium*

Because of their outspoken ubiquity and versatility, bacterial viruses (phages) constitute an inevitable and integral part of microbial ecology, and are now being recognized as an important selective pressure and/or advantage that continues to drive microbial evolution and behavior. Moreover, the ongoing evolutionary arms race between bacterial hosts and their viral parasites has endowed phages with fine-tuned strategies to interfere with or even reshape microbial physiology. Understanding bacteriophage infection and the impact it has on the bacterial host greatly depends on insights at the systems biology level. Our research focuses on the phage-based identification of new antibacterial targets and indicates a close interplay at the RNA, proteome (interactions & post translational modifications) and metabolome level of *Pseudomonas* phages.

Lytic bacteriophages inject their genome in the bacterial cytoplasm and immediately redirect the host metabolism towards phage genome replication and the production of virions. However, the mechanisms behind the molecular hijack are largely unknown. While bacteriophages infecting *Pseudomonas aeruginosa* have been known and studied for a long time, over 80% of their genes have an unknown function. Recent 'omics' techniques can lead to a drastic increase in the understanding of the struggle between virus and host to dominate the cellular metabolism during all stages of infection. The exploration of four levels of control (transcriptional, posttranscriptional and – translational, protein-protein interactions) and their influence on the bacterial metabolome are the key focus of this presentation. We are currently exploring the potential for biotechnological applications and antimicrobial design strategies of these phage-encoded gene products.

### **The Type VI secretion system**

#### **Recent insights into the export and activity of type VI secretion toxins**

*M. LeRoux<sup>1</sup>, R.L. Kirkpatrick<sup>1</sup>, E.I. Montauti<sup>1</sup>, B.Q. Tran<sup>2</sup>, Y.A. Goo<sup>2</sup>, D.R. Goodlett<sup>2</sup>, P.A. Wiggins<sup>3</sup>, J.D. Mougous<sup>1</sup>*

<sup>1</sup>*Microbiology, University of Washington, Seattle, USA*

<sup>2</sup>*Pharmaceutical Sciences, University of Maryland, Baltimore, USA*

<sup>3</sup>*Physics and Bioengineering, University of Washington, Seattle, USA*

Though they are by definition single-celled organisms, bacteria can exhibit properties more often ascribed to multicellular life. Our group aims to identify, characterize, and eventually, exploit, pathways that bacteria use for intercellular communication and competition. In this presentation, I will discuss our recent progress toward understanding the diversity of mechanisms by which antibacterial toxins delivered by the type VI secretion system act upon recipient cells. I will also describe our discovery that a conserved signaling pathway allows cells of the Gram-negative opportunistic pathogen *Pseudomonas aeruginosa* to mount a coordinated response to antagonism by competing bacteria.

**FEMS-2814**

**The Type VI secretion system**

**The *Pseudomonas aeruginosa* T6SS: a weapon for bacterial warfare**

A. Filloux<sup>1</sup>

<sup>1</sup>*Life Sciences, Imperial College London, London, United Kingdom*

Gram-negative bacteria have evolved various strategies to compete in hostile environments. Among them, secretion systems have attracted a lot of attention because of their clinical importance but also because of their complex architecture and regulation. The conserved bacterial type VI secretion system (T6SS) was initially associated with bacteria-host interaction but subsequently found to inject toxins into bacterial targets. These toxins have various activities, the best characterized of which are amidases, phospholipases and DNases.

*Pseudomonas aeruginosa* is an opportunistic pathogen, which has three T6SSs called H1- to H3-T6SS. We used a combination of structural and *in vivo* protein-protein interaction approaches to characterize molecular aspects of the H1-T6SS assembly of *Pseudomonas aeruginosa*. We also characterized several T6SS toxins and studied their mode of delivery and their impact on bacterial competition.

**FEMS-2951**

**The Type VI secretion system**

**Structure, function and dynamics of Type VI secretion system sheath**

M. Basler<sup>1</sup>

<sup>1</sup>*Biozentrum, University of Basel, Basel, Switzerland*

The bacterial Type VI secretion system (T6SS) is a large dynamic organelle that is functionally analogous to contractile tails of bacteriophages. T6SS is used by Gram-negative bacteria to inhibit adjacent cells via translocation of toxic effector proteins and thus play an important role in bacterial ecology. Time-lapse fluorescence light microscopy revealed that T6SS sheath, which powers the secretion, cycles between assembly, quick contraction, disassembly and re-assembly. Single cell analysis of subcellular localization of T6SS assembly revealed that T6SS organelle encoded by *Pseudomonas aeruginosa* H1-T6SS cluster is assembled and aimed to specifically retaliate against attack by other bacteria. I will present latest update on the structure, function and dynamics of T6SS as well on mechanisms of effector delivery. I will focus on the structure of the T6SS sheath and the implications for T6SS dynamics and assembly.

## **FEMS-0625**

### **Bacterial spores**

#### **Germination of spores of *Bacillus subtilis*: nothing but surprises**

P. Setlow<sup>1</sup>

<sup>1</sup>*Molecular Biology and Biophysics, UConn Health, Farmington, USA*

#### **Background**

Previous work has identified proteins essential for *Bacillus subtilis* spore germination as the: i) germinant receptors (GRs) that recognize nutrient germinants; ii) GerD protein essential for rapid GR-dependent germination; iii) SpoVA proteins that likely comprise a channel for dipicolinic acid (DPA) release early in germination; and iv) lytic enzymes that degrade the peptidoglycan cortex later in germination. Previous work has determined these proteins' locations in spores, some of their structures and some knowledge of how their function is regulated.

#### **Objectives**

Identify and understand the earliest spore germination events.

#### **Methods**

To help answer these latter questions we have examined germination of multiple individual *B. subtilis* spores under various conditions.

#### **Conclusions**

Surprising recent findings from this work include the following. 1) At approximately when spores become committed to germinate, spores' inner membrane permeability decreases and DPA begins to leak out, with this leakage more evident at higher temperatures. Following leakage of 10-20% of spores' DPA, the remainder is released in 1-2 min. The change leading to slow DPA leakage is unknown, but could be changes in spores' inner membrane, the DPA channel, or both. 2) Spores have memory of exposure to nutrient germinants, such that a 1<sup>st</sup> germinant pulse results in more germination following a 2<sup>nd</sup> germinant pulse. This memory is established before commitment, as memory is lost upon extended incubation, especially at elevated temperatures. Memory is formed by stimulation of any GR and can be accessed by stimulation of any GR. However, how spore memory is generated, stored and accessed are not known.

**Bacterial spores**

**The polar septum - the way how to set up asymmetry during sporulation in Bacilli and Clostridia**

I. Barak<sup>1</sup>, K. Muchova<sup>1</sup>, Z. Chromikova<sup>1</sup>, A.J. Wilkinson<sup>2</sup>, R. Valencikova<sup>1</sup>

<sup>1</sup>Department of Microbial Genetics,

Institute of Molecular Biology Slovak Academy of Sciences, Bratislava, Slovakia

<sup>2</sup>Department of Chemistry, Structural Biology Laboratory University of York, York, United Kingdom

A general problem in developmental biology concerns the process by which cells of one type divide to give dissimilar daughter cells. Even though these daughter cells may be genetically identical, they can differ morphologically and physiologically and have different fates. As one of the simplest differentiation processes, *Bacillus subtilis* sporulation represents an excellent model system for studying cell differentiation. Several decades of study of this process have provided insight into cell cycle regulation and development. The first clear morphological step in sporulation is formation of division septum at the polar site, which is fundamental to the development of highly resistant endospores formed by bacterial species as Bacilli and Clostridia. The earliest visible event in this asymmetric cell division is the formation of a Z-ring by FtsZ, a tubulin like protein, and E-ring by SpoIIIE at the future sporulation septum site.

There are many important advances in our understanding of asymmetric gene expression during spore formation with an emphasis on developmental stages that lead to asymmetric septum formation and especially to activation of the first compartment specific sigma factor - sigF. It is clear that SpoIIIE is a crucial constituent of the sporulation septum formation and an important determinant of the proper activation of sigF. However, we understand these processes only partially and there are few fascinating unanswered questions as: how SpoIIIE localises to the polar septum; how SpoIIIE causes FtsZ to relocate from mid-cell to the polar site; how SpoIIIE's phosphatase activity is controlled so that sigF activation is delayed until the septum is completed; what role SpoIIIE plays in septal thinning or what is the role of other proteins and Min system in this stage of sporulation.

### **Bacterial spores**

#### **The role of spores in *C. difficile* infection**

S.M. Cutting<sup>1</sup>

<sup>1</sup>*School of Biological Sciences, Royal Holloway University of London, Egham, United Kingdom*

*Clostridium difficile* infection (CDI) is an important nosocomial infection in the developed world and one for which no vaccine currently exists. In the USA alone about 28,000 people die each year and of these most occur from nosocomial infection. It is universally accepted that extensive antibiotic usage promotes germination of *C. difficile* spores in the GI-tract followed by secretion of toxins (A and B) from the live bacterium that then produce symptoms of disease (gastroenteritis and diarrhea). *C. difficile* is a spore-forming bacterium and both humans and animals can be asymptomatic carriers. It is also accepted that *C. difficile* can be acquired from the environment and there is evidence of transfer of animal strains (e.g., the 078 ribotype) to humans.

While the vegetative bacterium produces symptoms of disease there is compelling evidence that other virulence factors exist and that the spore plays an important role in infection. For example, oral administration of non-toxin producing spores confer protection to CDI in humans implying that other correlates of infection exist.

This talk will focus on two aspects of CDI. First, the characterization of proteins found on the surface of *C. difficile* spores and second, strategies we are using to vaccinate against CDI using mucosal delivery of *C. difficile* antigens and that are now in clinical trial.

Analysis of spore coat proteins has revealed a number of proteins that carry enzymatic properties of which one can be linked to inflammation. A second, BclA1, has been shown to play a distinct role in the initial stages of infection potentially by recognition of a specific receptor molecule in the gut mucosa.

**Structural analysis of proteins involved in peptidoglycan hydrolysis during spore germination**

G. Christie<sup>1</sup>, F.I. Ustok<sup>1</sup>, B. Al-Riyami<sup>1</sup>, D.Y. Chirgadze<sup>2</sup>

<sup>1</sup>Department of Chemical Engineering and Biotechnology, University of Cambridge, Cambridge, United Kingdom

<sup>2</sup>Department of Biochemistry, University of Cambridge, Cambridge, United Kingdom

A key event in the germination of spores of *Bacillus* and *Clostridium* species concerns depolymerisation of the thick layer of cortical peptidoglycan that surrounds the spore core. Cortical dissolution is achieved via the activities of a group of peptidoglycan lysins referred to as cortex lytic enzymes (CLEs). CLEs can be further sub-divided into those that cleave intact peptidoglycan, and those that function as cortical-fragment lytic enzymes (CFLEs). The molecular mechanisms that underpin the transition of inactive CLEs and CFLEs in the dormant spore, to catalytically active enzymes during spore germination, are poorly understood. In the current work we have used X-ray crystallography to examine CFLEs from both *Bacillus* (SleL) and *Clostridium* (SleM) spores in an attempt to gain structural insights to the regulation of CFLE activity. To date, high-resolution structural information has permitted relatively facile identification of the active sites and catalytic residues in the respective enzymes, and has revealed why SleL from *B. cereus* spores is significantly more catalytically efficient than the orthologous *B. megaterium* enzyme. Determination of the *C. perfringens* SleM crystal structure has additionally revealed unusual structural features that are probably involved in substrate or protein interactions. Finally, comparison of SleL and SleM crystal structures with the *Bacillus* CLE, SleB, has permitted the generation of hypotheses regarding the structural basis for CFLE substrate selectivity, which will be discussed during the presentation.

#### **Small RNA-based antiviral immunity in insects: defense and counter-defense**

R.P. van Rij<sup>1</sup>, A.W. Bronkhorst<sup>1</sup>, E. Girardi<sup>1</sup>, S.H. Merklings<sup>1</sup>, P. Miesen<sup>1</sup>,  
G.J. Overheul<sup>1</sup>, S. Schuster<sup>1</sup>, K.W. Van Cleef<sup>1</sup>

<sup>1</sup>*Medical Microbiology, Radboud University Medical Center, Nijmegen, Netherlands*

The RNA interference (RNAi) pathway senses virus infection to induce an antiviral response in insects. The ribonuclease Dicer-2 detects viral double-stranded RNA and generates viral small interfering RNAs (vsiRNAs), which are then used to restrict viral replication. Recent small RNA profiling studies demonstrated that both RNA and DNA viruses are targets of the RNAi response and identified the viral RNA substrates that trigger vsiRNA biogenesis. The importance of the antiviral RNAi pathway is underscored by the observation that viruses have evolved sophisticated mechanisms to counteract this immune response. More recently, it was proposed that another small RNA silencing mechanism, the piRNA pathway, also processes viral RNAs in *Drosophila* and mosquitoes. I will present recent insights into antiviral RNAi and discuss the dynamic interplay between host antiviral RNAi responses and virus counter-defense strategies.

**Insect-microbes interactions**

**The *Drosophila*-*Spiroplasma* interaction as a model to dissect the molecular mechanisms underlying insect endosymbiosis**

B. Lemaitre<sup>1</sup>

<sup>1</sup>*Global Health Institute, EPFL, Lausanne, Switzerland*

Virtually every species of insect harbors facultative bacterial endosymbionts that are transmitted from females to their offspring, often in the egg cytoplasm. These symbionts play crucial roles in the biology of their hosts. Many manipulate host reproduction in order to spread within host populations. Others increase the fitness of their hosts under certain conditions. For example, increasing tolerance to heat or protecting their hosts against natural enemies. Over the past decade, our understanding of insect endosymbionts has shifted from seeing them as fascinating oddities to being ubiquitous and central to the biology of their hosts, including many of high economic and medical importance. However, in spite of growing interest in endosymbionts, very little is known about the molecular mechanisms underlying most endosymbiont-insect interactions. For instance, the basis of the main phenotypes caused by endosymbionts, including diverse reproductive manipulations or symbiont-protective immunity, remains largely enigmatic. To fill this gap, we are dissecting the interaction between *Drosophila* and its native endosymbiont *Spiroplasma poulsonii*. This project will use a broad range of approaches ranging from molecular genetic to genomics to dissect the molecular mechanisms underlying key features of the symbiosis, including vertical transmission, male killing, regulation of symbiont growth, and symbiont-mediated protection against parasitic wasps. We believe that the fundamental knowledge generated on the *Drosophila*-*Spiroplasma* interaction will serve as a paradigm for other endosymbiont-insect interactions (ex. *Wolbachia*) that are less amenable to genetic studies.

**Insect-microbes interactions**

**How gut microbes interact with animals: insights from *Drosophila***

A. Douglas<sup>1</sup>

<sup>1</sup>*Daljit S. and Elaine Sarkaria Professor of Insect Physiology & Toxicology,  
Department of Entomology, Department of Molecular Biology and Genetics,  
Cornell University, Ithaca NY, USA*

**Background:** Animal surfaces and cavities provide multiple habitats for those microorganisms that can tolerate the conditions and exploit the resources provided by their animal hosts. Many of these microorganisms display adaptations for the host habitat, some of which are co-evolved with metabolic or immunity-related traits of the host. Teasing apart these interactions represents a major challenge, especially in humans and other mammals with very complex physiological systems and diverse microbial communities.

**Objectives:** To use the relationship between *Drosophila* and its gut microbiota as a model system to investigate the fundamentals of interactions between animals and their gut microbiota.

**Methods:** We have quantified the impact on the association of systematically varying the diet composition, microbiota composition and host genotype, using multiple methods including analysis of (meta)-genome-wide associations

**Conclusions:** Key traits that are influenced by host and microbial genetic factors are the abundance of the microorganisms in the gut and the energy status of the host, including metabolic rate and fat content. Our first datasets also point to the importance of among-microbe interactions in shaping the total function of the microbial community. Because the microbial community in *Drosophila* is relatively simple, it is feasible to investigate these interactions systematically.

**Insect-microbes interactions**

**Digesting the diversity: Ecology and evolution of the termite gut microbiota**

A. Brune<sup>1</sup>

<sup>1</sup>*Dept. of Biogeochemistry, MPI for Terrestrial Microbiology, Marburg, Germany*

Termites degrade lignocellulose with the help of their intestinal symbionts. The general role of the gut microbiota in the digestive process is slowly emerging, but the specific functions of individual populations and their evolutionary origin are still in the dark. Deep sequencing of the hindgut community revealed strong differences among the major host groups, and dramatic changes in the abundance of particular taxa coincide with major events in termite evolution. The acquisition of cellulolytic protists by an ancestral cockroach provided new habitats for bacterial symbionts, which colonize the surface and cytoplasm of the gut flagellates in all evolutionary lower termites. After the loss of flagellates in higher termites, the wood particles became available for bacterial colonization, providing new niches for fiber-digesting populations. While some lineages in the core microbiota may be cospeciating with termites since the early Cretaceous, others seem to be specifically selected by the microenvironmental conditions in insect guts. Experiments addressing the role of the host in the selection of its gut microbiota are hampered by the elaborate social system of termites and their obligate dependence on intestinal symbionts. However, the controlled inoculation of germ-free cockroaches with normal and foreign microbiota confirmed that host factors are important drivers shaping the gut microbial community.

**FEMS-3160**

**Bacterial cell biology**

**Mechanisms and evolution of bacterial morphology**

Y. Brun<sup>1</sup>

<sup>1</sup>*Biology, Indiana University, Bloomington, USA*

The diversity of shapes of organisms is one of the most fascinating aspects in the field of biology. While bacteria display a myriad of morphologies, the mechanisms that control morphogenesis and the evolution of bacterial morphology are not understood. I will describe the mechanisms that control morphological diversity in species related to *Caulobacter crescentus* that synthesize appendage-like extensions of the cell envelope at distinct sub-cellular positions. I will show that stepwise evolution of a specific domain of a developmental regulator led to the gain of a new function and localization of this protein, which drove the sequential transition in morphology. Our results indicate that evolution of protein function, co-option, and modularity are key elements in the evolution of bacterial morphology. In addition, I will show how evolutionary consideration of the mechanism of growth in the alphaproteobacteria led to the surprising discovery that polar growth, rather than the previously assumed binary fission, is the predominant mode of growth in a large group of the alphaproteobacteria that includes the plant pathogen *Agrobacterium tumefaciens* and the human pathogen *Brucella abortus*. Finally, I will describe new methods of peptidoglycan labeling that allow the detection of sites of peptidoglycan synthesis in live cells and in real time, and their use to study the mechanisms of peptidoglycan synthesis and to show for the first time that pathogenic Chlamydia have peptidoglycan, ending 50 years of speculation and debate concerning the chlamydial anomaly.

**Bacterial chromosome segregation at the single-molecule resolution**

D. Sherratt<sup>1</sup>, P. Zawadzki<sup>1</sup>, A. Upton<sup>1</sup>, S. Nolivos<sup>1</sup>

<sup>1</sup>Dept Biochemistry, University of Oxford, Oxford, United Kingdom

**Bacterial chromosome segregation at the single-molecule resolution**

How does a bacterial cell without a nucleus, without mitosis, and without extensive sister cohesion, organize, replicate, repair and segregate its chromosomes? We use live-cell super-resolution PALM and 3-D SIM imaging, alongside classical biochemistry and molecular genetics, and *in vitro* single-molecule biophysical techniques to address these questions. The presentation will focus on the sequential and coordinated action of Topoisomerase IV and the SMC complex, MukBEF, in *E. coli* chromosome segregation.

**Regulation of cell division in bacteria**

L. Søgaard-Andersen<sup>1</sup>

<sup>1</sup>Dept. of Ecophysiology, Max Planck Institute for Terrestrial Microbiology, Marburg, Germany

Background: Accurate positioning of the division site is essential for generating appropriately-sized daughter cells with the correct chromosome number. In bacteria, cell division initiates with assembly of the tubulin homologue FtsZ into a ring-like structure, the Z-ring. Thus, the position of Z-ring formation dictates the cell division site. Accordingly, all known systems that regulate positioning of the division site control Z-ring positioning.

Objective: We analyzed how the rod-shaped *Myxococcus xanthus* cells regulate positioning of the Z-ring at midcell.

Methods: Genetics, microscopy and *in vitro* analyses of proteins.

Conclusions: We report that PomX, PomY and the ParA-like ATPase PomZ are important for formation and positioning of the Z-ring. PomXYZ colocalize in a dynamically localized cluster and depend on each other for localization in this cluster. Early during the cell cycle this cluster localizes on the nucleoid away from midcell. Subsequently, the cluster relocates by directed motion to midcell and localizes here before and in the absence of FtsZ. PomZ stimulates the movement of the PomXYZ cluster to midcell in an ATP hydrolysis-dependent manner. *In vitro* PomX and PomY interact and stimulate PomZ ATPase activity. Moreover, PomY and PomZ separately inhibit FtsZ filament formation. We conclude that *M. xanthus* uses a novel system to precisely mark midcell for Z-ring formation and cell division. We propose that Z-ring formation is inhibited throughout cells by PomY and PomZ. At midcell, PomXYZ establish a zone that is permissive to Z-ring formation either by inhibition of PomYZ function and/or by direct stimulation of Z-ring formation.

#### The PALM nanostructure of FtsZ along the cell cycle of a pathogenic coccus

C. Morlot<sup>1</sup>, M. Jacq<sup>1</sup>, V. Adam<sup>2</sup>, D. Bourgeois<sup>2</sup>, C. Moriscot<sup>3</sup>, A.M. Di Guilmi<sup>1</sup>,  
T. Vernet<sup>1</sup>

<sup>1</sup>*Pneumococcus Group, Institute for Structural Biology, Grenoble, France*

<sup>2</sup>*Pixel Team, Institute for Structural Biology, Grenoble, France*

<sup>3</sup>*Methods and Electron Microscopy Group, Institute for Structural Biology, Grenoble, France*

Ovococci form a morphological group that includes several human pathogens (streptococci and enterococci). Their shape results from two modes of cell wall insertion, one allowing division, and another one allowing limited elongation. Both cell wall synthesis modes rely on a single cytoskeletal protein, FtsZ, since MreB is absent in ovococcal bacteria. Despite the central role of FtsZ in ovococci, a detailed view of the *in vivo* nanostructure of ovococcal Z-rings has been lacking thus far, limiting our understanding of their assembly and architecture.

We have developed the use of PhotoActivated Localization Microscopy in the ovococcus human pathogen *Streptococcus pneumoniae* by engineering spDendra2, a photoconvertible fluorescent protein optimized for this bacterium. Labeling of endogenously expressed FtsZ with spDendra2 revealed the remodeling of the Z-ring morphology along the division cycle at the nanoscale. Changes in the ring axial thickness and in the clustering propensity of FtsZ correlated with the advancement of the cell cycle. We observed double-ring sub-structures, suggestive of short-lived intermediates that may form upon initiation of septal cell wall synthesis. The nanostructural details provided in this work have been integrated in a model describing the morphology of the ovococcal Z-ring along the cell cycle.

**Closing Session**

**The Lwoff Award Presentation: The microbial methane cycle**

R.K. Thauer<sup>1</sup>

<sup>1</sup>*Biochemistry, Max Planck Institute for Terrestrial Microbiology, Marburg, Germany*

Globally, each year about 270 Gt CO<sub>2</sub> are net fixed via photosynthesis into biomass, mainly lignocelluloses. Of this biomass about 2% end up in anoxic environments low in sulfate, Fe<sup>3+</sup>, Mn<sup>4+</sup>, nitrate and/or nitrite, where biomass is fermented via syntrophic associations of anaerobic protozoa, fungi, bacteria and archaea to methane and CO<sub>2</sub>. The methane thus generated either accumulates in the sediments forming methane hydrates or diffuses into zones where the electron acceptors sulfate, Fe<sup>3+</sup>, Mn<sup>2+</sup>, nitrate, nitrite and/or O<sub>2</sub> are available and where methane is oxidized by anaerobic archaea and aerobic bacteria to CO<sub>2</sub>. Part of the methane also escapes into the atmosphere, where it is photochemically converted to CO<sub>2</sub>, and where methane is a potent greenhouse gas, which is of concern since the methane concentration in the atmosphere has doubled within the last 100 years. Many of the microbes involved in the methane cycle display a unique biochemistry, which my group helped to unravel within the last 50 years. In my lecture I will focus on the function and structure of the nickel enzyme methyl-coenzyme M reductase, which catalyzes in methanogenic archaea the methane forming step and in methanotrophic archaea the methane oxidizing step. The enzyme contains uniquely the nickel porphinoid F<sub>430</sub> as prosthetic group and, highly conserved, six postranslationally modified amino acids within the active site, amongst them a thioglycine, two C-methylated amino acids and an only recently discovered didehydroaspartate. The function of the posttranslational modifications has remained enigmatic and therefore also the catalytic mechanism of MCR.

Thauer, R. (2015) My lifelong passion for biochemistry and anaerobic microorganisms. *Annu. Rev. Microbiol.* 69: in press. doi: 10.1146/annurev-micro-091014-104344

#### **THE HUMAN GUT AS A RESERVOIR FOR ANTIBIOTIC RESISTANCE GENES**

*E. Buelow<sup>1</sup>, T. Bello Gonzalez<sup>2</sup>, J. Bayjanov<sup>1</sup>, W.A.A. de Steenhuijsen Piters<sup>1</sup>, D. Versluis<sup>2</sup>, M.W.J. van Passel<sup>2</sup>, H. Schmitt<sup>3</sup>, H. Smidt<sup>2</sup>, R.J.L. Willems<sup>1</sup>, M.J.M. Bonten<sup>1</sup>, W. van Schaik<sup>1</sup>*

<sup>1</sup>*Department of Medical Microbiology, University Medical Center Utrecht, Utrecht, Netherlands*

<sup>2</sup>*Laboratory of Microbiology, Wageningen University, Wageningen, Netherlands*

<sup>3</sup>*Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands*

#### **Background**

The human gut harbors a densely populated microbial ecosystem, termed the gut microbiota. The gut microbiota can serve as a reservoir for antibiotic resistance genes ('the resistome') and drug-resistant opportunistic pathogens.

#### **Objectives**

In this study, we determined the dynamics of the microbiota and the resistome in thirteen patients that were hospitalized in Intensive Care Units. Because gut-associated bacteria and their resistance genes may be shed into the environment through sewage, we also assayed the levels of antibiotic resistance genes in hospital sewage and in subsequent stages of wastewater treatment.

#### **Methods**

16S rRNA profiling, functional metagenomics, metagenomic sequencing and nanolitre-scale quantitative PCRs were used in this study.

#### **Conclusions**

The gut microbiota of hospitalized patients contained genes that are predicted to confer resistance to fourteen classes of antimicrobials. Levels of antibiotic resistance genes increased during ICU hospitalization and were associated with changing patterns of the composition of the microbiota. Sequencing of vector inserts in drug-resistant fosmid clones indicated that resistance genes were mainly carried by anaerobic gut commensals (*Clostridium* and *Bacteroides*). Resistance genes were associated with mobile genetic elements, which could facilitate horizontal gene transfer of resistance genes from commensal bacteria to opportunistic pathogens. Antibiotic resistance genes were abundant in hospital sewage but the influence of hospital sewage on the abundance of resistance genes in the wastewater treatment

plant was limited. Levels of resistance genes and human-associated bacteria further decreased during wastewater treatment, limiting the dispersal of antibiotic resistance genes from hospitals into the environment.

**SYNTHETIC BIOLOGY FOR THE DESIGN OF ANTIMICROBIAL PEPTIDES**

S. Schmitt<sup>1</sup>, M. Montalban-Lopez<sup>2</sup>, O.P. Kuipers<sup>2</sup>, D. Peterhoff<sup>3</sup>, R. Wagner<sup>3</sup>,  
S. Panke<sup>1</sup>, M. Held<sup>1</sup>

<sup>1</sup>D-BSSE, ETH Zürich, Basel, Switzerland

<sup>2</sup>Department of Genetics, University of Groningen, Groningen, Netherlands

<sup>3</sup>Institute of Medical Microbiology and Hygiene, University of Regensburg,  
Regensburg, Germany

**Background**

The number of multi drug resistant pathogens is constantly growing and novel antibiotic substances are desperately needed in order to at least maintain the status quo. Ribosomally synthesized antimicrobial peptides are not yet exploited for human applications despite an indisputable potential. Among those, lantibiotics, a class of posttranslationally modified and thioether-ring bearing antimicrobial peptides, show desirable properties as high but specific antimicrobial activity and excellent stability.

**Objectives**

We follow a synthetic biology approach for the generation of novel lantibiotics employing the blueprint of natural lantibiotics. Based on their structural and functional features, natural lantibiotics are dissected into modular subunits. These subunits are then shuffled to generate thousands of novel, putative active, chimeric lantibiotics. The lantibiotic genes are subsequently produced by combinatorial DNA *de novo* synthesis. These libraries will then be screened for molecules with high antimicrobial activity.

**Methods**

To enable for high screening rates we developed a platform based on nL-sized reaction vessels (nL-reactors) that are used for peptide production and activity-screening in a single step and at rates of 10<sup>5</sup> variants per day. Library cells are grown to microcolonies within nL-reactors along with a sensor strain. Cells secreting an active antimicrobial peptide will deactivate the sensor cells. Clearance of an nL-reactor from the sensor thus indicates the presence of a strain secreting a highly active peptide.

**Conclusions**

10<sup>4</sup> different chimeric variants derived from the module-shuffling of ten natural lantibiotics were analyzed. Several interesting antimicrobials have been isolated, demonstrating for the first time the generation of new-to-nature lantibiotics by module-shuffling.

**Poster Discussion: Discovery of Novel Antibiotics**

**DOUBLE LEADING: LANTIBIOTIC - MICROCIN HYBRIDS**

A. Buivydas<sup>1</sup>, M. Montalban-Lopez<sup>1</sup>, O.P. Kuipers<sup>1</sup>

<sup>1</sup>*Molecular Genetics, University of Groningen, Groningen, Netherlands*

**Background**

Lantibiotics and microcins form different groups of posttranslationally modified bacterial peptides mainly produced by Gram-positive and Gram-negative bacteria, respectively. Most of these peptides exhibit a potent antimicrobial activity, more active even than some antibiotics. Maturation of a peptide begins with a propeptide which is guided throughout specific modification events due to leader peptide (an amino acid sequence recognized by particular modification biomodule). The leader peptide is proteolitically removed in the last steps of peptide modification making the modified peptide active. Posttranslational modifications endorse lantibiotics and microcins with high target-specific activities and stability against proteolysis.

**Objectives**

To design plug-and-play biomodules for production of novel peptides containing both, lantibiotic- and microcin-specific posttranslational modifications.

**Methods**

We used a synthetic biology approach to design biomodules. We utilized peptide modification systems cloned under different controlled promoters to assure gradual and temporal activity of designed biomodules. Codon optimized synthetic genes of designed model peptides to be modified were employed together with modification machineries.

**Conclusions**

This is a unique case where posttranslational modifications from two different peptide classes are fused together into a single peptide chain *in vivo*. Here, we also show the possibilities of employing chimeric leader peptides for substrate recognition and procession by particular posttranslational modification machineries.

**MECHANISMS OF ANTIBACTERIAL ACTION OF CATIONIC PEPTIDE  
WARNERIN**

V. Korobov<sup>1</sup>, L. Lemkina<sup>1</sup>, T. Poludova<sup>1</sup>, L. Filatova<sup>1</sup>

<sup>1</sup>Laboratory of microorganisms' biochemical development,  
Institute of Ecology and Genetics of Microorganisms UB RAS, Perm, Russia

**Background**

Rapid development of antibiotic resistance of bacteria necessitates the search for new natural compounds inhibiting the growth and functioning of pathogenic microflora.

**Objectives**

To study the antibacterial mechanisms of warnerin, a new peptide from lantibiotic family that demonstrate the sequence of events causing the death of attacked bacterial cells.

**Methods**

Outcomes of warnerin attack of *Staphylococcus epidermidis* 33 GISK (Moscow) were analyzed using the combination of different methods such as polarography (respiration), spectrography (intracellular potassium loss), fluorescence assay of membrane potential dynamics and hydroxyl radicals' formation, electron and atomic-force microscopy of cell structure damages

**Conclusions**

Peptide introduction into the bacterial incubation medium results in the increase in their oxygen consumption followed by rapid cellular release of potassium ions and sharp decline of intracellular ATP concentration. Apparently, the disturbance of ATP-linked electron transport along the respiratory chain favors their accumulation on iron-sulfur centres. This results in increase of free Fe<sup>2+</sup> ions and as a consequence, to the elevation of hydroxyl radical concentrations. Peptide inhibition of ATP formation is accompanied by marked proton accumulation on the outer side of bacterial membrane, particularly in its adjacent layers of peptidoglycane. This facilitates the autolytic hydrolase extrusion from the binding sites and to uncontrolled total bacteriolysis that is revealed by microscopic data. Results of investigation evidence for the pluripotent antibacterial action of warnerin that point to expressed prospects for its practical use.

**Poster Discussion: Discovery of Novel Antibiotics**

**ISOLATION AND CHARACTERIZATION OF NOVEL BACTERIOPHAGES WITH  
LYTIC ACTIVITY AGAINST MULTIDRUG RESISTANT PATHOGENS**

S. Latz<sup>1</sup>, A. Wahida<sup>1</sup>, A. Arif<sup>1</sup>, K. Ritter<sup>1</sup>, H. Horz<sup>1</sup>

<sup>1</sup>Department of Medical Microbiology, Medical Faculty RWTH Aachen, Aachen, Germany

**Background**

With the emerging threat of infections caused by multidrug-resistant bacteria and scarce prospects of newly introduced antibiotics in the future, bacteriophages (phages) are currently being reconsidered as alternative therapeutics. However, the full breath of phage diversity suitable for treatment of bacterial infections is still largely unexplored.

**Objectives**

This study aims at providing an overview of the general occurrence of bacteriophages (with therapeutic potential) in natural environments and at devising strategies for their rapid characterization and classification at molecular level.

**Methods**

Novel phages were isolated from various aquatic systems (e.g. from general and hospital wastewater, activated sludge samples from sewage plants, streams, rivers, ponds and lakes). Environmental samples were pre-incubated with clinical isolates of multidrug-resistant bacteria. Enriched bacteriophages were subsequently obtained with the double agar layer plaque assay. "PhiSigns"

(<http://www.phantome.org/phisigns/>) was used for phage identification based on the detection of signature genes. Genomic comparison of phages was performed based on digitized fluorescent restriction-fragment-length-polymorphism-analysis (fRFLP).

**Conclusions**

For roughly 50% of tested bacterial strains lytic bacteriophages were found against multidrug-resistant *Pseudomonas aeruginosa*, *Klebsiella pneumoniae* and *Enterobacter* sp. with waste water samples harbouring the highest phage diversity. By contrast no bacteriophages were isolated against multidrug-resistant *Staphylococcus aureus* and *Acinetobacter baumannii*. PhiSigns combined with fRFLP proofed to be a useful tool for rapid phage identification, which is the base for their proper selection for ultimate whole genome sequencing. *S. aureus* and *A. baumannii* phages require additional isolation steps such as FeCl<sub>3</sub>-precipitation and/or use of

subinhibitory antibiotic-concentrations for enhancing plaque visibility on agar plates.

Poster Discussion: Discovery of Novel Antibiotics

**THERAPEUTIC MONOCLONAL ANTIBODIES AGAINST THE GLOBALLY SPREAD MULTI-DRUG RESISTANT ESCHERICHIA COLI CLONE ST131-O25B:H4**

G. Nagy<sup>1</sup>, V. Szijártó<sup>1</sup>, L. Guachalla<sup>1</sup>, Z. Visram<sup>1</sup>, E. Nagy<sup>1</sup>

<sup>1</sup>Microbiology and in vivo Models, Arsanis Biosciences GmbH, Vienna, Austria

**Background**

The globally spread multi drug resistant *E. coli* clone ST131-O25b:H4 is responsible for a significant proportion of multi-drug resistant extraintestinal infections. By definition, isolates of this clone express the O25b antigen, whose unique structure has been resolved recently.

**Objectives**

We aimed to develop humanized monoclonal mAbs against the O25b antigen that may provide an alternative adjunct or stand-alone therapeutic option against this *E. coli* lineage.

**Methods**

Murine mAbs against the unique O25b antigen were generated by standard hybridoma technique. Following a primary screening, selected antibodies were subjected to humanization. Specificity and binding characteristics were assessed by immunoblots and ForteBio using purified antigens. Surface staining of ST131-O25b isolates irrespective of the capsular type expressed was shown by flow cytometry. Upon surface binding, the humanized antibodies induced complement mediated bactericidal activity *in vitro*. Passive immunization with the humanized mAbs elicited high level of protection at low mAb doses in a murine model of bacteremia. All whole cell assays were performed with bacteria grown in standard culture medium as well as in depleted pooled human serum in order to mimic *in vivo*-like conditions.

**Conclusions**

Humanized mAbs against *E. coli* O25b antigen were developed that elicited bactericidal activity *in vitro* and showed protection *in vivo*. Prophylactic passive immunization of colonized individuals or adjunct therapy of infected patients by mAbs may replace/substitute antibiotic therapy against this drug resistant clone. Relevant cases could be identified by the co-developed companion diagnostic tool.

Università degli Studi di Milano, Milano, Italy

<sup>2</sup>Département de Biochimie de Microbiologie et de Bioinformatique, Université Laval,  
Québec City, Canada

**Background**

*Lactococcus garvieae*, one of the most important pathogens in the aquaculture sector, has been recently recognized as an opportunistic human pathogen. However, little is known about the factors controlling of its growth.

**Objectives**

The aim of this project is to isolate and characterize temperate and virulent phages of *L. garvieae*.

**Methods**

Forty-five *L. garvieae* strains isolated from various ecological niches were tested for the presence of inducible prophages. Virulent phages were also isolated from different environments. Morphological and genomic characteristics of the new phages were studied through transmission electronic microscope (TEM), DNA restriction profile, protein profile, host range, and in few cases, genomic sequences.

**Conclusions**

Twenty temperate phages belonging to the *Siphoviridae* family and five new virulent phages able to infect *L. garvieae* strains have been isolated and partially characterized. Temperate phages, integrated into the genome of the host cell, promoted genome plasticity and appeared to be involved in gene mobilization. Virulent and strain-specific phages may be useful as alternatives to antibiotics to treat *L. garvieae* infections.

**ALGAL VIRUS PRODUCTION IS NEGATIVELY AFFECTED BY PHOSPHORUS AND NITROGEN LIMITATION, BUT THIS MAY BE COUNTERACTED BY NUTRIENT ASSIMILATION DURING INFECTION**

D.S. Maaß<sup>1</sup>, C.P.D. Brussaard<sup>1</sup>

<sup>1</sup>*Biological Oceanography, Netherlands Institute for Sea Research (NIOZ), 't Horntje, Netherlands*

**Background**

Viruses are a main cause of phytoplankton mortality, thereby controlling their community composition and driving biogeochemical cycling in the marine environment. Phytoplankton growth and production is often limited by nitrogen (N) and/ or phosphorus (P), which can affect the virus growth characteristics upon infection. The influence of nutrient limitation on phytoplankton – virus interactions are, however, still poorly studied. As climate change will lead to an expansion of stratified and consequently nutrient limited oceanic regions, it is important to understand how phytoplankton mortality rates in the future marine environment will be affected by these changes.

**Objectives**

Our goal was to study the effects of N- and P-limitation on virus host interaction and the potential relieve of these effects by the uptake of nutrients during viral infection.

**Methods**

Therefore, cultures of the the phytoplankton species *Micromonas pusilla* and *Phaeocystis globosa* were grown semicontinuously under limitation of either P, N, or NP until the moment of infection. Upon infection the abundances of host cells and viruses were monitored to obtain one-step growth curves.

**Conclusions**

Nutrient limitation led to elongated viral latent periods (up to 3-fold) and strongly reduced (up to 8-fold) burst sizes, whereby the outcome was dependent on both the species and the limiting nutrient involved. Furthermore, the negative effects of P-limitation on virus production in the picophytoplankter *M. pusilla* could be overcome by spiking the infected and P-limited cultures with small pulses of inorganic and organic P, simulating bacterial remineralization and supply by lysis of neighboring cells, respectively.

## **REMARKABLE DIVERSITY AMONG NOVEL DENSOVIRUSES FROM CRICKETS**

P. Tijssen<sup>1</sup>, H.T. Pham<sup>1</sup>, Q. Yu<sup>1</sup>

<sup>1</sup>*Virology, INRS–Institut Armand-Frappier, Laval, Canada*

### **Background**

Densoviruses are members of the Parvoviridae family infecting invertebrates. Since 2009, a cricket densovirus, AdDV, caused a severe epidemic in the \$ 600-million cricket industry in North-America.

### **Objectives**

During the last 18 months, we also received samples of diseased crickets from North America, Europe and Japan that were negative for AdDV. Electron microscopy demonstrated that these samples contained densovirus-like particles. Objectives of this study included characterization of these virus(es), cloning, sequencing, and X-ray crystallography.

### **Methods**

A SISPA method was used to detect the pathogens (J Virol 88:12152). Sequencing of the amplicons identified those with identities to known viruses allowing by primer extension to obtain the complete genomes and cloning in suitable vectors to obtain infectious clones. Sequencing revealed that some were novel circoviruses and a novel ambisense densovirus (Genome Announc. 1(2):e00079-13, 1(3):e00328 and 131(6):e00914-13). However, the greatest surprise was a densovirus with a segmented genome (AdSDV). NS- and VP- coding sequences are in separate segments of about 3.3 kb. Both NS- and VP- segments are flanked by identical hairpin terminal sequences but lack ITRs. The two ORFs for VP arose through recombination between a mosquito brevidensovirus and AdDV. The downstream ORF with AdDV-VP1up-like phospholipase A2 could be spliced to the C-terminus of the major capsid protein. Currently, the capsid structure (X-ray crystallography) and transcription strategy of AdSDNV.

### **Conclusions**

A brevidensovirus that normally infects only mosquitoes has adapted itself through recombination with AdDV to crickets. These findings necessitate a revision of the definition and taxonomy of parvoviruses.

**VACCINE-TYPE ATTENUATING MUTATIONS IN HIGHLY PASSAGED STRAIN OF VARICELLA ZOSTER VIRUS**

J. Jeon<sup>1</sup>, Y. Won<sup>1</sup>, I. Kim<sup>1</sup>, J. Yoon<sup>1</sup>, M. Kim<sup>1</sup>, C. LEE<sup>1</sup>

<sup>1</sup>Microbiology, Chungbuk National University, Cheongju, Korea

Background: Varicella-zoster virus (VZV) is causative agent for chickenpox and zoster. Live attenuated vaccines have been developed based on Japanese Oka strain and Korean MAV/06 strain. Comparison of the complete sequences between vaccine and wild-type strains suggested at least 24 mutations important for attenuation in vaccine strains. Certain strains with high in vitro passage history such as the strains Ellen and 32p72 contained some of the vaccine-type mutations. Objective: In this study, we attempted to understand vaccine-type attenuating mutations in highly passaged VZV strains.

Methods: Genome sequences of clinical strains with different passages were determined by next-generation sequencing and compared with those of other VZV strains.

Conclusion: Vaccine-type mutations were found at position 106262 (T→C) in the Korean clinical strain YC01 passage 32 and at positions 560 (T→C), 105169 (A→G), 106262 (T→C) and 107252 (T→C) in YC01 passage 61. Similar mutations were also found in high-passaged another clinical strain YC02 at positions 560, 106262 and 107252. Same mutations at 106262 and 107252 were found in the strains Ellen and 32p72. Thus, in the course of in vitro passaging of VZV, mutations at 106262 and 107252 seemed to occur first, and followed by mutation at 560. Direct PCR sequencing of these positions in YC01 and YC02 strains at various passages identified the passage numbers when the attenuating mutations occurred. Further studies of in vitro passaging under attenuating conditions such as low temperature or guinea pig cells will help to understand the mechanism of attenuating mutations in VZV.

**TIME SINCE ONSET OF DISEASE AND INDIVIDUAL CLINICAL MARKERS  
ASSOCIATE WITH TRANSCRIPTIONAL CHANGES IN UNCOMPLICATED  
DENGUE**

H. van den Ham<sup>1</sup>

<sup>1</sup>*Viroscience, Erasmus MC University Medical Center, Rotterdam, Netherlands*

**Background**

Dengue virus (DENV) infection causes viral haemorrhagic fever that is characterized by extensive activation of the immune system.

**Objectives**

The aim of this study is to investigate the kinetics of the transcriptome signature changes during the course of disease and the association of genes in these signatures with clinical parameters.

**Methods**

Sequential whole blood samples from DENV infected patients in Jakarta were profiled using affymetrix microarrays, which were analysed using principal component analysis, limma, gene set analysis, and weighted gene co-expression network analysis.

**Conclusions**

Time since onset of disease associates with the shift in transcriptome signatures from immunity and inflammation to cell cycle and repair mechanisms in patients with non-severe dengue. The strong association of time with blood transcriptome changes hampers both the discovery as well as the potential application of biomarkers in dengue. Clinical diagnosis (according to the WHO classification) does not associate with differential gene expression. However, network analysis did show that that key clinical markers, including platelet count, fibrinogen, albumin, IV fluid distributed per day and liver enzymes SGOT and SGPT, strongly correlate with gene modules that are enriched for genes involved in the immune response. The expression level of these gene modules may support earlier detection of disease progression as well as clinical management of dengue.

## **CHARACTERIZING THE VIROME OF THE ENTOMOPATHOGENIC FUNGUS BEAUVERIA BASSIANA**

I. Kotta-Loizou<sup>1</sup>, M.A. Typas<sup>2</sup>, R.H.A. Coutts<sup>1</sup>

<sup>1</sup>*Division of Cell & Molecular Biology, Imperial College London, London,  
United Kingdom*

<sup>2</sup>*Department of Genetics & Biotechnology, University of Athens, Athens, Greece*

### **Background**

Entomopathogenic fungi are of scientific interest because they enable analysis of virus-host interactions and can be used as biocontrol agents of insect pests. The deuteromycetous fungus *Beauveria bassiana* has a widespread geographical distribution and a wide host range. Mycoviruses have been described mostly in phytopathogenic fungi and are occasionally associated with hypovirulence, while in entomopathogenic fungi presence of mycoviruses has been reported only rarely.

### **Objectives**

The aim of the present study is to detect and analyse the viruses present in a collection of *B. bassiana* isolates sourced from worldwide locations.

### **Methods**

Population studies, RT-PCR, cloning and sequencing, hybridization experiments, time-course studies and transmission electron microscopy (TEM) were used to characterize the virome of *B. bassiana*.

### **Conclusions**

A population study revealed that 17/75 (22.7%) *B. bassiana* isolates harbor dsRNA elements. Two members of the *Partitiviridae* family, *B. bassiana* partitivirus-1 and -2 (BbPV-1 and BbPV-2), have been sequenced, while TEM revealed the presence of virus-like particles. Hybridization experiments revealed that BbPV-1 and BbPV-2 are present in seven *B. bassiana* isolates derived from different hosts and geographical origins. Additionally, four members of the *Totiviridae* family, originating from the Iberian Peninsula and the Canary Islands, have been partially sequenced. Furthermore, two previously uncharacterized viruses, *B. bassiana* polymycovirus-1 (BbPmV-1) and *B. bassiana* non-segmented virus-1 (BbNV-1), have been detected and fully sequenced and the prevalence of further PmV-like viruses in *B. bassiana* is currently under investigation. Finally, a time-course study revealed a strong negative

correlation between the copy numbers of viral dsRNA and the developmental stages of the fungus.

**CHARACTERIZATION OF VIRULENCE FACTORS AND IMMUNE-STIMULATING ANTIGENS IN *VIBRIO SALMONICIDA***

S.F. Nørstebø<sup>1</sup>, M.V. Wade<sup>2</sup>, A.M. Bjelland<sup>1</sup>, P.M. Fidopiastis<sup>2</sup>, H. Sørum<sup>1</sup>

<sup>1</sup>Food Safety and Infection Biology, Norwegian University of Life Sciences, Oslo, Norway

<sup>2</sup>Center for Coastal Marine Sciences, California Polytechnic State University, San Luis Obispo, USA

**Background**

*Vibrio salmonicida* is the cause of cold-water vibriosis in farmed Atlantic salmon. The disease manifests as a hemorrhagic septicemia, with a mortality ranging from 3-90 %. In the 1980s, the disease was a major challenge to the Norwegian aquaculture industry, but it is now being effectively controlled by the use of oil-based vaccines. Nevertheless, in recent years there have been some reports of disease outbreaks. In 2013, 13 Norwegian fish farms were diagnosed with cold-water vibriosis, all localized in the three northernmost counties of Norway.

**Objectives**

The knowledge on virulence factors of *Vibrio salmonicida* and the subsequent immune response of the fish is limited. As bacteria adapt to their current environment, a bacterium isolated from a diseased fish will not be identical to the same species cultivated *in vitro*. The aim of this study was to explore the phenotype of bacteria present *in vivo*.

**Methods**

We have grown *Vibrio salmonicida* in semi-permeable implants in live fish and analyzed bacterial protein expression by two-dimensional gel electrophoresis and tandem mass spectrometry. The experiment was approved by the Norwegian Animal Research Authority (approval no. ID6228).

**Conclusions**

Our findings may contribute to the knowledge on disease progression in cold-water vibriosis, as well as to provide novel targets for more effective vaccines. Also, the

study may provide insights in the course of disease for other bacterial infections in fish.

## **IDENTIFICATION AND TYPING OF LACTOCOCCUS GARVIEAE BASED ON MALDI TOF MS**

M. Pérez-Sancho<sup>1</sup>, A. Casamayor<sup>2</sup>, E. Pulido<sup>2</sup>, J.F. Fernández-Garayzabal<sup>2</sup>,  
L. Domínguez<sup>2</sup>, A.I. Vela<sup>2</sup>

<sup>1</sup>Campus CEI Moncloa-Centro Visavet, Universidad Complutense de Madrid, Madrid, Spain

<sup>2</sup>Centro Visavet, Universidad Complutense de Madrid, Madrid, Spain

### **Background**

MALDI-TOF-mass spectrometry (MS) has emerged as a powerful technique for the routine identification of microorganisms in clinical microbiology laboratories allowing an easier and faster diagnosis than conventional phenotypic and molecular methods. We have evaluated the suitability of MALDI-TOF for the rapid identification of *Lactococcus garvieae* the etiological agent of lactococcosis, a septicemic infection affecting different wild and farmed fish species, and recognized also as an opportunistic emerging human pathogen.

### **Objectives**

Assessment of the reliability of MALDI-TOF MS for the identification of *Lactococcus garvieae*

### **Methods**

A total of 35 isolates from different host and environments were obtained from the culture collection of VISAVET were used in the study. The identification results obtained by MALDI TOF were compared with those obtained by biochemical identification (API 32 Strep) and by a species- specific PCR assay (Zlotkin et al. 1998. J Clin Microbiol 36, 983-985). Mass spectra acquisition and analysis was performed on a Bruker UltraFlex platform (Bruker Daltonics) using MALDI Biotyper™ 3.0 software in the automatic mode using a matrix of saturated solution of  $\alpha$ -HCCA. In addition, a subset of isolates was subjected to PFGE.

### **Conclusions**

The majority of peaks were obtained in the range from m/z 2000 to 10000. The proteomic results matched with those of genotypic approach. Our results also showed some differences in MS spectra in *L. garvieae* isolates recovered from different origins/hosts suggesting the possible identification of molecular biomarkers for *L. garvieae*. Our study demonstrates that proteomics identification using MALDI TOF MS could be a reliable approach for identifying and discriminating this microorganism.

**Poster Discussion: Veterinary Microbiology**

**O SEROGROUPS OF ENTEROPATHOGENIC (EPEC) AND SHIGATOXIGENIC (STEC) ESCHERICHIA COLI FROM**

*I. Fakh<sup>1</sup>, J.N. Duprez<sup>1</sup>, D. Thiry<sup>1</sup>, L. Jouant<sup>1</sup>, A. Iguchi<sup>2</sup>, M. Saulmont<sup>3</sup>, J. MAINIL<sup>1</sup>*

<sup>1</sup>*Infectious Diseases Bacteriology, FARAH and Faculty of Veterinary Medicine, LIEGE-SART TILMAN, Belgium*

<sup>2</sup>*Animal and Grassland Sciences, Faculty of Agriculture UOM, MIYAZAKI, Japan*

<sup>3</sup>*Bacteriology, Association Régionale de Santé et d'Identification Animale, CINEY, Belgium*

**Background**

*Escherichia coli* producing the attachment-effacement (AE) lesion (EPEC) and/or Shiga toxins (STEC) cause enteritis and (bloody) diarrhoea in young calves and in humans, and are also present in the intestines of healthy cattle. Besides the O157:H7 serotype, EPEC and STEC can belong to more than sixty O serogroups. Of them, 8 have been most frequently identified worldwide: O5, O26, O103, O111, O118, O121, O145 and O165, with some also causing diarrhoea in young calves.

**Objectives**

This study aimed at identifying the pathotypes and the O serogroups of STEC and EPEC isolated from <1-month-old diarrhoeic calves in Wallonia, Belgium.

**Methods**

(i) 233 enterohaemolysin-producing *E. coli* were isolated at ARSIA between November 2008 and February 2014 from diarrhoeic calves after growth on EHLY Medium<sup>®</sup>. They were tested with a triplex PCR targeting the *stx1*, *stx2* (Shiga toxins) and *eae* (AE lesion) genes.

(ii) triplex PCR-positive *E. coli* were assayed with two pentaplex PCR targeting the specific genes coding for the nine O serogroups listed above and for the O104 serogroup.

**Conclusions**

(i) 206 isolates tested positive with the triplex PCR. The most frequent pathotypes were *eae+stx1+* (102 isolates), *eae+* (78 isolates) and *eae+stx1+stx2+* (13 isolates).

(ii) the most frequent serogroups of EPEC and STEC were O26 (57 isolates) and O111 (36 isolates). A few additional isolates tested positive for the O103, O5, O145, O121 and O157 serogroups.

(iii) the future is to compare these EPEC and STEC with those isolated from healthy cattle and from humans, to identify host- and age-specific properties.

# CHARACTERISTICS AND ANTIMICROBIAL SUSCEPTIBILITY OF TRUEPERELLA PYOGENES ISOLATED FROM BOVINE MASTITIS CASES IN CHINA

D. Han<sup>1</sup>, A. rashad<sup>1</sup>, W. Chen<sup>1</sup>, G. Liu<sup>1</sup>, Y. Liu<sup>1</sup>, Z. Deng<sup>1</sup>, O. Szenci<sup>1</sup>, C. Bajcsy<sup>1</sup>,  
B. Han<sup>1</sup>

<sup>1</sup>College of Veterinary Medicine, China Agricultural University, Beijing, China

## Background

*Trueperella (T) pyogenes* is an opportunistic pathogen causes suppurative diseases in dairy cows. However, the pathogenesis and antibiotics resistance of *T. pyogenes* are still unclear.

## Objectives

*T. pyogenes* isolates morphological characteristics, the presence of genes (*plo*, *cbpA*, *fimA*, *fimC*, *fimE*, *fimG*, *nanH*, *nanP*, *tetW*, *ermX*, *ermB*), biofilm formation, the cytopathological effects in intracellular assay and antimicrobial resistance were investigated.

## Methods

*T. pyogenes* was isolated from 50 out of 275 clinical and subclinical bovine mastitis cases in China. Both pyolysin (*plo*) and collagen-binding protein (*cbpA*) virulence factor genes were detected by conventional PCR in all *T. pyogenes* isolates. The tissue culture plate method was used to assay the capacity of *T. pyogenes* for biofilm formation and showed that 90% of *T. pyogenes* isolates were able to form biofilms with different production amount. Minimum inhibitory concentrations (MICs) of 14 antimicrobial agents were determined and observed high susceptibility to rifampin (96%), while high resistance to trimethoprim–sulfamethoxazole (90%) and bacitracin (98%). Intracellular assay revealed that 4 different *T. pyogenes* isolates had different cytopathological effects on infected bovine mammary gland epithelial cells.

## Conclusions

18% *T. pyogenes* isolates indicates that *T. pyogenes* is important contributors to bovine mastitis. Moreover, the within-host quantitative, spatial, high occurrence of multidrug-resistant, biofilm producing and temporal dynamics of *T. pyogenes* interactions are key factors to better understand how immunity acts on infections with bacteria and how they evade immune surveillance; thus, highlighting the need for prudent use of antimicrobial agents in veterinary medicine (This research was supported by projects No. 2012BAD12B03, No. 313054, No. 20120008110042, No. 2014M561102 and No. GDT20141100043).

**FUNCTIONAL RESILIENCE OF MICROBIAL ECOSYSTEMS IN SOIL: HOW IMPORTANT IS A SPATIAL ANALYSIS?**

S. König<sup>1</sup>, T. Banitz<sup>2</sup>, F. Centler<sup>1</sup>, K. Frank<sup>2</sup>, M. Thullner<sup>1</sup>

<sup>1</sup>*Environmental Microbiology, Helmholtz Centre for Environmental Research, Leipzig, Germany*

<sup>2</sup>*Ecological Modelling, Helmholtz Centre for Environmental Research, Leipzig, Germany*

**Background**

Microbial life in soil is exposed to fluctuating environmental conditions influencing the performance of ecosystem services such as biodegradation.

**Objectives**

However, as this environment is typically very heterogeneous, spatial aspects can be expected to play a major role for the ability to recover from a stress event.

**Methods**

To determine key processes for functional resilience, scenarios with varying stress intensities were simulated within a microbial simulation model and the biodegradation rate in the recovery phase measured. Besides temporal monitoring, results were analyzed regarding spatial and mechanistic aspects. Parameters including microbial growth and dispersal rates were varied over a typical range to consider microorganisms with varying properties.

**Conclusions**

Results of the mechanistic and spatial view show that key factors for functional recovery depend on stress intensity and the location of the observed habitats. The limiting factors near unstressed areas are spatial processes (motility and substrate diffusion), with increasing distance microbial growth becomes more important. To confirm this, we repeated the simulations including a dispersal network representing fungi in soil. The system benefits from an increased spatial performance due to higher bacterial mobility.

With these simulations we show the importance of spatial aspects even at the mm-scale for recovering after a severe stress event in a highly heterogeneous environment such as soil. In consequence a spatial-mechanistic view is necessary for examining the functional resilience as the temporal view alone could not have led to these conclusions.

Further research should explore the importance of a spatial view for quantifying functional resilience also after complex stress regimes.

**Poster Discussion: Environmental Microbiology**

**PHYSIOLOGIC AND GENOMIC CHARACTERIZATION OF A NOVEL NITROSPIRA SPECIES ENRICHED UNDER ANAEROBIC, DENITRIFYING CONDITIONS**

M.A.H.J. van Kessel<sup>1</sup>, S. Lüscher<sup>1</sup>, D.R. Speth<sup>1</sup>, M.S.M. Jetten<sup>1</sup>, H.J.M. Op den Camp<sup>1</sup>

<sup>1</sup>Microbiology, Radboud University, Nijmegen, Netherlands

**Background**

Members of the genus *Nitrospira* are dominant in many natural habitats and of vital importance for wastewater treatment. They are chemolithoautotrophic organisms capable of growth with nitrite and CO<sub>2</sub> as sole energy and carbon source. It further has been demonstrated that some *Nitrospira* can utilize simple organic carbon compounds and molecular hydrogen as alternative substrates and can switch to nitrate reduction under oxygen limitation. However, this metabolism has been assumed to be a survival strategy and in most systems studied so far *Nitrospira* was outcompeted by denitrifying organisms when anoxic conditions prevailed.

**Objectives**

Here, a community of nitrogen cycle bacteria was enriched from the anaerobic compartment of a biofilter connected to a recirculating aquaculture system.

**Methods**

The culture was fed with filtered water from the aquaculture system, supplemented with ammonium, nitrite and nitrate.

**Conclusions**

A stable enrichment culture was obtained which anaerobically converted ammonium, nitrite and nitrate into dinitrogen gas. The culture was dominated by anaerobic ammonium-oxidizing *Brocadia* species, a denitrifier (*Denitratisoma*), and a *Nitrospira* species. Anammox bacteria and *Nitrospira* co-aggregated, while the denitrifiers formed separate clusters. This culture shows that anaerobic ammonium oxidizers and nitrite oxidizers, who were considered to be mutually exclusive, can be grown as a stable co-culture. Furthermore, this shows that some *Nitrospira* species can be competitive under nitrate-reducing conditions. This study demonstrates another unexpected lifestyle for an organism believed to be only competitive under aerobic lithoautotrophic conditions. It further indicates that *Nitrospira* in combination with anammox can be of interest for anoxic wastewater treatment systems.

**BACTERIAL PROFILING OF SAHARAN DUST DEPOSITION IN THE ATLANTIC OCEAN USING SEDIMENT TRAP MOORINGS – YEAR ONE RESULTS**

C. Munday<sup>1</sup>, G.J.A. Brummer<sup>1</sup>, M. van der Does<sup>1</sup>, L. Korte<sup>1</sup>, J.B.W. Stuut<sup>1</sup>

<sup>1</sup>Geological and Chemical Oceanography,  
Netherlands Institute for Sea Research (NIOZ), 't Horntje, Netherlands

**Background**

Large quantities of dust are transported from the Sahara Desert across the Atlantic Ocean towards the Caribbean each year, with a large portion of it deposited in the ocean. This dust brings an array of minerals, nutrients and organic matter, both living and dead. This input potentially fertilizes phytoplankton growth, with resulting knock-on effects throughout the food chain. The input of terrestrial microbial life may also have an impact on the marine microbial community.

**Objectives**

The aim is to understand the links between dust input and the bacterial community and how this relates to ocean productivity and the carbon cycle.

**Methods**

The current multi-year project consists of a transect of floating dust collectors and sub-surface sediment traps placed at 12°N across the Atlantic Ocean. Sediment traps are located 1200m and 3500m below the sea surface and all are synchronized to collect samples for a period of two weeks.

**Conclusions**

The first set of sediment trap samples were recovered using the *RV Pelagia* in November 2013 with promising results. Results from 7 sediment traps (three at 1200m and four at 3500m) were obtained. In general, the total mass flux decreased as distance from the source increased and the upper traps generally held more material than those at 3500m. Denaturing Gradient Gel Electrophoresis (DGGE) was used as a screening technique, revealing highly varied profiles, with the upper (1200m) traps generally showing more variation throughout the year. Several samples have been submitted for high throughput DNA sequencing which will identify the variations in these samples.

<sup>1</sup>Chemistry, National Research Council Postdoctoral Fellow, Washington DC, USA

<sup>2</sup>Chemistry, U.S. Naval Research Laboratory, Washington DC, USA

<sup>3</sup>Center for BioMolecular and Material Science Engineering, U.S. Naval Research Laboratory, Washington DC, USA

<sup>4</sup>Acoustics, U.S. Naval Research Laboratory, Washington DC, USA

<sup>5</sup>Geosciences, U.S. Naval Research Laboratory, Stennis Space Center MS, USA

**Background**

Biological systems are frequently exposed to microwave radiation. Many studies have investigated the influence of microwaves on these systems, but controversy over methods to distinguish between thermal and non-thermal microwave effects remains.

**Objectives**

To differentiate between non-thermal and thermal microwave effects on a physiology of a microorganism, a thermophilic bacterium was grown in a constant-temperature microwave or a convection oven. Comparing the growth properties of the thermophile in these conditions will reveal non-thermal microwave effects on cell growth and

physiology. Biophysical and biochemical analysis will demonstrate changes in morphology and chemical composition arising from microwave exposure.

### **Methods**

Cell growth was analyzed by optical density (OD) measurements (supported by independent quantitative DNA analysis), and cell morphologies were characterized using electron microscopy imaging (SEM, TEM), dynamic light scattering (DLS), and atomic force microscopy (AFM). AFM was also used to probe the biophysical characteristics of the cells, in conjunction with nano-infrared spectroscopy (Nano-IR). Attenuated total reflectance infrared spectroscopy (ATR-IR) and fatty acid methyl ester (FAMES) analysis were used to determine biochemical differences between cells grown in microwave and oven conditions.

### **Conclusions**

Thermophilic bacteria were grown in a synthetic microwave such that thermal effects and microwave effects were distinguishable. These data demonstrate that there are physiological differences between cells cultured in a dielectric field and a convection oven, and that microwaves induce non-thermal changes to the structure, physiology, and chemical composition of the organism.

**Poster Discussion: Environmental Microbiology**

**MYXOBACTERIA IN PEAT BOGS AND FEN – AN ASTONISHING DIVERSITY**

K.I. Mohr<sup>1</sup>, T. Zindler<sup>1</sup>, J. Wink<sup>1</sup>

<sup>1</sup>*Microbial Strain Collection, Helmholtz Centre for Infection Research, Braunschweig, Germany*

**Background**

Increasingly appearing resistances to antibiotics and the subsequent need for new bioactive substances is one of the fundamental challenges of infection research. Myxobacteria have a rich secondary metabolism, which places them among the best known natural product producers. To date more than 100 new metabolites and more than 500 derivatives were described from these soil dwelling, predatory microorganisms. In the past it turns out that in particular new families, genera and species of myxobacteria are reliable sources for new compounds.

**Objectives**

Promising sources for the isolation of new myxobacteria are uncommon habitats like, for example, peat bogs or fen, which are characterized by low pH values. This habitat has been neglected with regard to the isolation of myxobacteria in the past. In our study, the diversity of myxobacteria in moor-samples from the Harz-region was evaluated by standard cultivation methods as well as by cultivation independent 16S rRNA-clone bank analyses.

**Methods**

A total of 297 clones of myxobacterial origin were sequenced and compared to sequences of cultures, isolated from these samples, by phylogenetic analyses. It turned out that the majority of myxobacteria is only represented by clone sequences and could not be cultivated. Comparing these sequences to sequences of a public database (NCBI) revealed that most of these uncultivated myxobacteria are exclusively related to other uncultivated myxobacterial sequences from acidic soils.

**Conclusions**

This suggests that peat bogs and fen harbor a big diversity of new myxobacterial species, genera and even families which themselves harbor a great potential of urgently needed, new secondary metabolites.

Poster Discussion: Environmental Microbiology

**THE MICROORGANISM THAT NEVER READ THE LITERATURE - FASTEST GROWING PHOTODAMAGE TOLERANT ALGA ISOLATED FROM DESERT CRUSTS, DEPENDS ON PIONEER FILAMENTOUS CYANOBACTERIA SPECIES TO SURVIVE DESICCATION**

H. Treves<sup>1</sup>, H. Raanan<sup>1</sup>, N. Keren<sup>1</sup>, Y. Shotland<sup>2</sup>, I. Ohad<sup>1</sup>, A. Kaplan<sup>1</sup>

<sup>1</sup>Plant and Environmental Sciences, Hebrew University, Jerusalem, Israel

<sup>2</sup>Chemical Engineering, Shamoon College of Engineering, Beer-Sheva, Israel

**Background**

With the premise that unique capabilities can be found in microorganisms facing extremely harsh conditions, we focused our efforts on desert biological sand crusts (BSC), one of the harshest environments to support life. Recently, we have isolated a small green alga (named *Chlorella ohadii*), which does not conform to some of the basic fundamentals in microbial ecology and photosynthesis:

**Objectives**

1. Acquired ability to acclimate to extreme environments is usually accompanied by reduced performance under optimal conditions. We intend to show that *C. ohadii* **does not obey this rule**. In its natural habitat, *C. ohadii* is facing diurnal desiccation-hydration cycles, vast temperature amplitudes and extremely high illumination intensities, yet when grown under optimal laboratory conditions it exhibits the fastest growth rates ever reported for an alga.
2. After many years of research, some feel that we have elucidated the functioning of the photosynthetic machinery, and what sets the upper limit for algal growth. However, the unparalleled fast growth, extremely high photosynthetic rates and resistance to photodamage, suggest this **may not be the case**. Namely, *C. ohadii* has been shown to be completely resistant to photoinhibition, and its productivity was unaffected by irradiances as high as twice full sun light.
3. Survival of *C. ohadii* in its BSC habitat depends on close association with filamentous cyanobacteria; **a unique and novel mode of interspecies interaction**.

**Methods**

We wish to present detailed physiological analysis of the unique properties supporting this phenomenal growth and resistances, combined with insights from their genomic, transcriptomic and metabolomic characterization.

**Conclusions**

**LEVANSUCRASE OF PSEUDOMONAS SYRINGAE AS PRODUCER OF NOVEL PREBIOTIC FRUCTANS: A STRUCTURE-FUNCTION STUDY OF THE ENZYME**

M. Gromkova<sup>1</sup>, K. Mardo<sup>1</sup>, T. Visnapuu<sup>1</sup>, T. Alamäe<sup>1</sup>

<sup>1</sup>Genetics, Institute of Molecular and Cell Biology University of Tartu, Tartu, Estonia

**Background**

Gut microbiota has numerous roles in human life and its significance has thus far been underestimated. Therefore, more detailed studies on diversity and metabolism of gut microbiota are needed.

**Objectives**

Gut microbiota can be shaped by prebiotics. Levan-type ( $\beta$  2,6-linked) fructans can be considered as potential prebiotics<sup>[1]</sup>. We have synthesized levan and levan-type fructooligosaccharides by heterologously expressed levansucrase Lsc3 of *Pseudomonas syringae* pv. tomato. These substrates should affect gut microbiota as were perfectly fermented by a gut generalist *B. thetaiotaomicron*<sup>[2]</sup>. Here we focus on structure-function relationships of the Lsc3 protein and its biotechnological potential.

**Methods**

The His-tagged Lsc3 protein was site-directedly mutated, biochemical methods were used to characterize the mutant proteins and 3D structure modelling was applied to interpret the results.

**Conclusions**

Levansucrase Lsc3 has high polymerizing activity (up to 80%) and extremely high stability confirming its biotechnological potential for the synthesis of fructans. Several novel catalysis-related positions for levansucrases were revealed and their predicted location on a 3D model of Lsc3 will be presented.

<sup>4</sup>TIFN, NIZO food research, Ede, Netherlands

**Background**

*Lactococcus lactis* is industrially employed to manufacture fermented dairy products. Spray drying is the cheapest preservation method for *L. lactis* starter cultures, but during this process cultures encounter heat and oxidative stress, resulting in low survival. Viability of starter cultures is essential for their role in dairy acidification, supporting the need to understand and improve their robustness.

**Objectives**

We have measured the ability of 39 *L. lactis* strains to survive industrially relevant stresses. This set of strains contained different *L. lactis* strains from dairy as well as plant origin. The observed 4-log variation in heat and oxidative stress survival was compared with genomic content, resulting in the identification of genes associated with robustness. Presence and activity of genes can play an important role in the observed diversity in robustness.

**Methods**

Therefore, four *L. lactis* strains with varying robustness phenotypes were fermented under twelve different conditions, varying in temperature, salt concentration, pH, and oxygen level. Cells were harvested at exponential phase of growth for transcriptome analysis and survival measurements.

**Conclusions**

The varying growth conditions resulted in up to 4-log differences in robustness towards heat and oxidative stress. Moreover, clear differences in gene expression profiles were observed. Correlation of robustness phenotypes and gene expression levels revealed transcriptome signatures for oxidative and heat stress survival. For strain MG1363 this included the *metC-cysK* operon, involved in methionine and cysteine metabolism, which triggered us to grow this strain in the absence of

cysteine, resulting in elevated expression levels of the *metC-cysK* operon and concomitant enhanced robustness towards oxidative stress.

<sup>2</sup>Department of Food Environmental and Nutritional Sciences (DeFENS),  
University of Milan and Sacco srl, Milan-Cadorago, Italy

**Background**

The proto-cooperation between *Streptococcus thermophilus* and *Lactobacillus delbrueckii* subsp. *bulgaricus* in the yogurt consortium enhances the growth rate and size of each population. In contrast, the independent growth of the two species in milk leads to a slower growth rate and a smaller population size.

**Objectives**

In this study, we evaluated how urease activity of *S. thermophilus* might affect the the intracellular pH of *L. delbrueckii*, modulating its bioenergetics during milk fermentation.

**Methods**

Urease-mediated intracellular alkalization of *S. thermophilus* and *L. delbrueckii* was evaluated by flow cytometry using cFSE as pH-dependent fluorescent probe. Lactose consumption and lactic acid production was followed *in vivo* by <sup>13</sup>C-NMR analysis. D-L lactic acid production in milk was measured enzymatically. For the evaluation of the pH-dependent glycolysis efficiency, glucose and lactic acid were measured by HPLC.

**Conclusions**

We observed that intracellular alkalization caused by urea hydrolysis or the addition of ammonia to milk boosted lactic acid production in *S. thermophilus* and in *L. delbrueckii* when the species were grown separately or in combination. Therefore, we propose that urease activity acts as an altruistic cooperative trait, which is costly for urease-positive individuals but provides a local benefit because other individuals can take advantage of urease-modulated pH. Compared to the interactions that are known to occur between *S. thermophilus* and *L. delbrueckii* in the yogurt consortium, the modulation of the bioenergetic efficiency due to the intracellular pH alkalization represents a new type of cooperation that directly affects the kinetic parameters of enzymes involved in homolactic fermentation in both the species.

**LISTERIA MONOCYTOGENES OF SEQUENCE TYPE 121 HARBOR SPECIFIC ADAPTATIONS SUPPORTING PERSISTENCE IN FOOD PRODUCTION PLANTS.**

K. RYCHLI<sup>1</sup>, A. Müller<sup>1</sup>, A. Zaiser<sup>1</sup>, M. Wagner<sup>1</sup>, S. Schmitz-Esser<sup>1</sup>

<sup>1</sup>Department for Farm Animals and Veterinary Public Health,  
Institute for Milk Hygiene, Vienna, Austria

**Background**

The foodborne pathogen *Listeria monocytogenes* is able to survive for months and even years in food production environments. Among a great strain diversity particularly strains belonging to sequence type (ST)121 are persistent in food production plants.

**Objectives**

To elucidate the molecular determinants responsible for persistence of *L. monocytogenes*.

**Methods**

We analysed the genomes of two *L. monocytogenes* ST121 strains, which persisted for up to eight years in food production plants in Ireland and Austria. Additionally we characterized two ST121 strain-specific genetic features: Tn6188 and *lin0464/lin0465*.

**Conclusions**

All ST121 genomes are highly similar and show a tremendously high degree of conservation among prophages and particularly among their plasmids, which are usually variable parts of genetic information in bacteria. This remarkably high level of conservation suggests a strong selective pressure.

In addition, all ST121 strains share adaptations related to persistence in food production environments such as the presence of Tn6188, a transposon responsible for increased tolerance against quaternary ammonium compounds, and the presence of homologues of the *L. innocua* genes *lin0464* and *lin0465*, a transcriptional regulator and a putative pfpl protease. Deletion of *lin0465* resulted in reduced survival under oxidative and alkaline conditions suggesting a role in stress response. Furthermore all ST121 strains reveal a yet undescribed insertion harboring recombination hotspot (RHS) repeat proteins, which are most likely involved in

competition against other bacteria. In conclusion we show that *L. monocytogenes* ST121 strains are highly similar to each other harboring conserved regions which provide fitness adaptations to survival in food production environments.

**USING DYNAMIC SINGLE CELL BIOLOGY TO DISSECT INJURY,  
RESUSCITATION AND DEATH PHENOMENA IN STRESSED POPULATIONS OF  
ESCHERICHIA COLI**

S. Govers<sup>1</sup>, A. Ghosh<sup>1</sup>, A. Cambré<sup>1</sup>, E. Gayan<sup>1</sup>, A. Aertsen<sup>1</sup>

<sup>1</sup>*Microbial and Molecular Systems, KU Leuven, Leuven, Belgium*

**Background**

While inimical food preservation approaches often result in heavily damaged and stressed populations of foodborne pathogens and spoilage microorganisms, very little is known about the actual molecular and genetic events and dynamics that govern the (sub)lethal injury and subsequent resuscitation or death of these cells. Nevertheless, insights into these phenomena might be decisive for a proper understanding of the resulting behavior and evolvability of the surviving subpopulation.

**Objectives**

In this study, we set out to monitor and dissect (sub)lethal injury and resuscitation phenomena in populations and cells of *Escherichia coli* that are stressed by heat or high hydrostatic pressure treatment.

**Methods**

Directed evolution, genetics and time-lapse fluorescence microscopy.

**Conclusions**

Based on adaptive mutations, genetics and live cell biology, different subcellular processes and structures have been delineated and monitored that play a role in the heterogeneous injury and resuscitation dynamics of high temperature or pressure stressed *E. coli* cells and populations, thereby revealing a surprising impact on the spatial dynamics of nucleoids and protein aggregation inside stressed cells.

**MAXIMIZING BIOTECHNOLOGICAL PRODUCTION OF 3-HYDROXYPROPIONALDEHYDE AS A NATURAL FOOD PRESERVATIVE WHILE MINIMIZING ITS CONVERSION TO TOXIC ACROLEIN**

C. Engels<sup>1</sup>, C. Schwab<sup>1</sup>, M.J.A. Stevens<sup>1</sup>, S.J. Sturla<sup>1</sup>, C. Lacroix<sup>1</sup>

<sup>1</sup>Health Sciences and Technology, Swiss Federal Institute of Technology, Zurich, Switzerland

**Background**

3-hydroxypropionaldehyde (3-HPA) has strong antimicrobial activity and application potential as a natural food preservative for disinfection of minimally processed vegetables. During glycerol metabolism, *Lactobacillus reuteri* DSM 20016T can accumulate 3-HPA, which undergoes reversible dimerization and hydration, and can be further converted enzymatically into inactive 1,3-propanediol (1,3-PD), restoring intracellular redox potential. Dehydration of 3-HPA resulting in acrolein, a toxic metabolite, is also possible, however, conditions promoting this transformation have not been fully understood due to the lack of analytical methods to simultaneously quantify 3-HPA as well as acrolein.

**Objectives**

The aim of this study was to maximize the capacity for biotechnological processing of glycerol to 3-HPA using *L. reuteri*, while accounting for the accumulation of acrolein after production and storage to evaluate toxicological risk.

**Methods**

Strategies to improve 3-HPA production included the addition of redox-active compounds during glycerol fermentation to prevent conversion to 1,3-PD, the usage of immobilized cells resulting in high densities of viable cells as well as the optimization of process parameters in batch and fed-batch processes. Special attention was paid to cultivation conditions of *L. reuteri* prior to glycerol conversion. Acrolein and 3-HPA were simultaneously quantified using a newly established analytical method employing ion-chromatography with pulsed amperometric detection.

**Conclusions**

Redox-active compounds, process conditions and pre-treatment of *L. reuteri* cultures influenced 3-HPA yield as well as ratio of 3-HPA to 1,3-PD. Temperature and pH

optimization prevented formation of acrolein during biotechnological production and storage, promoting the safety of 3-HPA when applied as natural food preservative.

**CANDIDA GLABRATA BIOFILMS RESPONSE TO AMPHOTERICIN B**

C. Fortuna Rodrigues<sup>1</sup>, S. Silva<sup>1</sup>, J. Salgado<sup>1</sup>, L. Abrunhosa<sup>1</sup>, A. Venâncio<sup>1</sup>,  
J. Azeredo<sup>1</sup>, M. Henriques<sup>1</sup>

<sup>1</sup>Centre of Biological Engineering, University of Minho, Braga, Portugal

**Background**

*Candida* species are responsible for recurrent human infections, mostly in immunocompromised patients, due to their high vulnerability. *Candida glabrata* has been showing to have a major role in these infections being the second most prevalent species involved in human fungemia. Amphotericin B (AmB), a common antifungal drug, is a hospital-environment exclusive polyene, normally being efficient when used to fight candidiasis.

**Objectives**

The main goal of this work was to infer about the influence of AmB in *Candida glabrata* biofilms formation and its effect on matrix composition and *ERG* genes expression.

**Methods**

*Candida glabrata* biofilms were formed in the presence of AmB and analyzed by dry weight. Moreover, *ERG* genes expression was evaluated by qRT-PCR and matrix was analyzed in terms of composition in carbohydrates, proteins, beta-glucans and a new finding: ergosterol.

**Conclusions**

In addition to an inefficient reduction of the *C. glabrata* biofilms, this work showed that *ERG* genes seem to be less involved than the matrix composition in *C. glabrata* biofilms response to AmB. Specifically, *C. glabrata* biofilms matrices respond with an increase of carbohydrates, particularly beta-1,3 glucans, and with a decrease of total proteins. The ergosterol values did not expressively changed in the presence of AmB.

The present work support the theory of multifaceted mechanisms developed by *C. glabrata* biofilms as response to the presence of AmB.

<sup>3</sup>Unit of Microbiology, Belgian Nuclear Research Centre SCK•CEN, Mol, Belgium

<sup>4</sup>Department of Pediatric Pulmonology Cystic Fibrosis Clinic and Pediatric Infectious Diseases, UZ Brussel, Brussels, Belgium

<sup>5</sup>Bio-engineering Sciences, Vrije Universiteit Brussel Brussels, Brussels, Belgium

**Background**

Chronic *Pseudomonas aeruginosa* lung infections are the main cause of morbidity in cystic fibrosis (CF) patients. Previously, we have sequenced the genome of the transmissible Belgian epidemic strain CF\_PA39. This CF-adapted strain has been present in the UZ Brussel hospital environment for at least ten years. Furthermore, earlier experiments showed that culturing *P. aeruginosa* PAO1 in a low fluid shear environment, obtained by means of the Rotating Wall Vessel (RWV) technology, leads to the formation of a biofilm phenotype comparable to that observed in the CF lung.

**Objectives**

To study the effect of fluid shear on biofilm formation by an adapted *P. aeruginosa* CF strain in artificial sputum medium (ASM) at the genotypic, transcriptomic, and phenotypic level.

**Methods**

In this study, an RWV experiment was performed that closely resembled the *in vivo* situation by inoculating this adapted CF isolate in ASM in the RWV either with or without two glass beads, simulating high and low fluid shear conditions, respectively. Scanning electron microscopy (SEM) was utilized to determine biofilm formation in both conditions, while RNAseq and qPCR was used to study gene expression in both conditions.

**Conclusions**

Increasing fluid shear in the RWV model disrupted biofilm formation of an adapted *P. aeruginosa* CF isolate.

In accordance with the biofilm disruption, several genes involved in denitrification, tryptophane synthesis, choline metabolism, and alginate biosynthesis were down-regulated in the high fluid shear condition, resembling the planktonic stage of growth. Furthermore, we identified small RNAs that are differentially expressed.

**CELL-CELL COMMUNICATION PROVIDES FITNESS BENEFITS TO POPULATIONS OF *LISTERIA MONOCYTOGENES* IN THE SOIL ENVIRONMENT**

D. Garmyn<sup>1</sup>, A.L. Vivant<sup>1</sup>, L. Gal<sup>1</sup>, P. Piveteau<sup>1</sup>

<sup>1</sup>Agroécologie, UMR Agroécologie 1347, Dijon, France

**Background**

*Listeria monocytogenes* is a ubiquitous opportunistic human pathogen detected in many habitats spanning from the farm environment to food industry and the gastrointestinal tract.

Cell-cell communication participates to the adaptation of bacteria to their environment. In the species *Listeria monocytogenes*, the Agr system is required for full virulence and biofilm formation but its actual role is still poorly understood.

**Objectives**

To investigate whether the ability to communicate provides a benefit to *L. monocytogenes* in soil, a complex environment combining biotic and abiotic characteristics.

**Methods**

Deletion of the gene coding the response regulator or the signal propeptide. Population dynamics of the mutant and/or parental strains in soil microcosms. Both unsterilised and sterilised soils were investigated.

**Conclusions**

Deletion of the gene coding the regulator or the signal did not affect population dynamics in sterilized soil but survival was altered in biotic soil suggesting that the Agr system was involved to face the complex soil biotic environment. This was confirmed by co-incubation experiments. The fitness of the response negative mutant was lower either in the presence or absence of the parental strain but the fitness of the signal negative mutant depended on the strain with which it was co-cultured. Survival of the signal negative mutant was higher when co-cultured with the parental strain than when co-cultured with the response negative mutant. These results showed that the ability to respond to communication provided a benefit to listerial cells. These results might also indicate that in soil, the Agr system controls private goods rather than public goods.

**REGULATORY RNA ARISES FROM 3'-UTR OF AHL SENSOR ENCODED RNA AFTER ITS PREPROCESSING IN PECTOBACTERIUM ATROSEPTICUM**

L.V. Shlykova<sup>1</sup>, N.E. Gogoleva<sup>1</sup>, V.Y. Gorshkov<sup>1</sup>, Y.V. Gogolev<sup>1</sup>

<sup>1</sup>The Laboratory of Molecular Biology,

Kazan Institute of Biochemistry and Biophysics Kazan Scientific Center of the Russian Academy of Sciences, Kazan, Russia

**Background**

In a broad group of proteobacteria two quorum sensing-related genes, which encode synthase of autoinducers and their sensor, respectively, have convergent topology and overlap by their 3'-ends. It was suggested that the expression of one gene may antagonize the transcription of another one because of the convergent arrangement of these genes.

**Objectives**

We proposed that the topology of quorum sensing-related genes of plant pathogenic bacterium *Pectobacterium atrosepticum*, *expI* and *expR*, determines the mechanism of regulation of their expression.

**Methods**

We noticed that *expR* gene lacks any obvious transcriptional stop signals. Using chain-specific RT-qPCR we found that at the stationary growth phase *expR* mRNAs having long 3'-untranslated region (UTR) were formed and the expression of oppositely oriented *expI* gene was simultaneously decreased. It is likely, that RNA products of the *expR* regulatory gene may inhibit the expression of the autoinducer synthase gene through the interactions with *expI* mRNA. Using 3'-RACE method we found that at the stationary growth phase the extended *expR* transcripts underwent preprocessing resulting in their break down into two fragments. The first fragment encompassed the entire length of open reading frame (ORF) of *expR* gene and the second one included only a long 3'-UTR having a predicted regulatory function.

**Conclusions**

We found that *cis*-encoded RNA may participate in the regulation of expression of two convergent functionally related genes. The length of one of two transcripts varies respective to the cell growth phase affecting the expression of oppositely oriented gene. Moreover, *cis*-encoded regulatory RNAs arises from protein encoded RNAs that undergo preprocessing in their 3'-UTR.

<sup>2</sup>Department of Veterinary Disease Biology Food Safety and Zoonoses, University of Copenhagen, Frederiksberg C, Denmark

<sup>3</sup>Departments of Pharmacology and Chemistry and Biochemistry. Skaggs School of Pharmacy and Pharmaceutical Sciences, University of California at San Diego, La Jolla, USA

**Background**

Interactions among members of polymicrobial infections can result in altered pathogen behaviours such as enhanced virulence, biofilm formation or antibiotic tolerance, which may influence the disease phenotype and clinical outcome of the infection. *Pseudomonas aeruginosa* and *Staphylococcus aureus* are important opportunistic human pathogens and are both part of the polymicrobial infection communities in human hosts. Cell-cell communication can play a major role in the interaction behaviors between these bacteria, which subsequently can affect the physiology of the individual strains. However, the extent to which evolutionary processes may remodel interspecies interactions and bacterial physiology during the course of infection and therapy is currently not understood.

**Objectives**

Therefore, the aim of this study was to analyze *in vitro* interactions between *S. aureus* and a human host adapted *P. aeruginosa* strain from a dominant lineage, DK2, that have evolved through decades of growth in chronically infected patients.

**Methods**

By using a combination of *in vitro* agar assays, molecular genetics and MALDI-TOF imaging mass spectrometry we demonstrate that DK2 – in contrast to other *P. aeruginosa* strains - show a commensal-like interaction with *S. aureus* during *in vitro* co-culturing, where the growth activity of *P. aeruginosa* was increased in the presence of *S. aureus*. The commensal interaction was observed both under aerobic and anaerobic conditions as well as during growth on artificial CF sputum medium, however was abolished with *S. aureus* strains mutated in the *agr* quorum sensing system.

**Conclusions**

Our results suggest that metabolic transformations during interaction with *S. aureus* enhance the growth activity of *P. aeruginosa*.

**ADVANCEMENTS TOWARDS A SYSTEM-LEVEL UNDERSTANDING OF SUBAERIAL BIOFILMS INHABITING OUTDOOR STONE MATERIALS**

*F. Villa<sup>1</sup>, P. Stewart<sup>2</sup>, I. Klapper<sup>3</sup>, J. Jacob<sup>4</sup>, F. Cappitelli<sup>5</sup>*

*<sup>1</sup>Dipartimento di Scienze per gli Alimenti la Nutrizione e l'Ambiente, Università degli Studi di Milano, Milano, Italy*

*<sup>2</sup>Center for Biofilm Engineering, Montana State University, Bozeman, USA*

*<sup>3</sup>Department of Mathematics, Temple University, Philadelphia, USA*

*<sup>4</sup>Northeast Region Historic Architecture Conservation and Engineering Program, National Park Service, New York, USA*

*<sup>5</sup>Dipartimento di Scienze per gli Alimenti la Nutrizione e l'Ambiente, Università degli Studi di Milano, Milano, Italy*

**Background**

Many of the world's most precious artworks are made of stone. Their irreversible deterioration due to biological attack is a worldwide concern. Microorganisms colonize outdoor lithic surfaces and develop into biofilms at the interface solid/air (subaerial biofilms, SABs), which, in turn might cause aesthetic, chemical and physical decay. Although it has been estimated that at least 99% of the world's microbial biomass exists in biofilms, the role and behavior of microorganisms within the biofilm matrix and their complex interactions with the external environment is still unknown.

**Objectives**

This work provides a pioneering and multidisciplinary research to investigate the behavior of microorganisms within the biofilm matrix for sorting out time-spatial relationships and to elucidate microorganism-EPS, inter-organism, biofilm-atmosphere and biofilm-stone interactions.

**Methods**

This work spans sophisticated molecular, chemical, physical and data modeling techniques and it is approached from two complementary angles:

- 1- Lab-scale study to delineate specific transcriptional responses of mono- and multi-species biofilms as well as the biofilm-stone interactions under controlled environmental conditions.
- 2- Real heritage case studies to investigate the shifts in the microbial community structure and function under different environmental conditions. Through comparing phylogenetic and functional diversity under different environmental scenarios, we

provide evidence that any intuition gained from the lab-scale experiments is relevant to true environmental biofilms.

## **Conclusions**

The findings obtained so far will contribute to better understand the complexity of all the interactions encountered within SAB communities, and how these interactions may influence the biofilm outcome and the biodeterioration of the stone materials under different environmental conditions.

<sup>2</sup>Department of Environmental sciences,  
Norwegian University of Life Sciences (NMBU), Ås, Norway

<sup>3</sup>School of Biological Sciences, University of East Anglia (UEA), Norwich,  
United Kingdom

**Background**

The reduction of nitrite to NO is considered the defining step of denitrification and a point of no return due to the toxicity of NO. Nevertheless, some accumulation of NO is necessary since it is central to the induction of its reductase and frequently also its enzymatic origin. A positive feedback loop perpetuated by a toxic substance is intuitively a play with fire. However, phenotypic studies of organisms known, or assumed to hold a product induced nitrite reductase have with few exceptions revealed stringent NO control.

**Objectives**

We studied the gas kinetics of *P. denitrificans* during the oxic-anoxic transition in order to reveal new aspects of NO as a regulator of denitrification.

**Methods**

The core instrumentation was a semi-automatic incubation system similar to that described by Molstad *et al.* (2007), where relevant headspace gases are monitored in respiring batch cultures.

**Conclusions**

In cultures incubated at 20°C, [NO] reached a semi-steady state at ~15nM. This homeostasis could almost entirely be explained by an estimated *in vivo* K<sub>m</sub> of 50nM for NO reductase. Although assumedly eliminating toxic effects, upholding such low [NO] appears to have some drawbacks. By combining experimental data with modelling approaches, we found strong evidence that the gross majority of cells were essentially entrapped in anoxia due to delayed induction of nitrite reductase. In contrast, when incubated at 30°C, [NO] was elevated (~75nM) and the entire population apparently succeeded in switching to N-oxide reduction. This illustrates some of the challenges of wielding a substance with such a double-edged nature: toxic intermediate and essential regulator in one.

**METHANOL AS A SUBSTRATE FOR METHANOGENESIS OF THE PRINCIPAL HUMAN GUT ARCHAEAL COMMENSAL METHANOBREVIBACTER SMITHII**

N. Gaci<sup>1</sup>, G. Borrel<sup>2</sup>, W. Tottey<sup>1</sup>, P.P. Chaudhary<sup>1</sup>, C. Gasc<sup>1</sup>, P. Peyret<sup>1</sup>, J.F. Brugère<sup>1</sup>

<sup>1</sup>EA 4678 CIDAM, Clermont Université - Université d'Auvergne, Clermont-Ferrand, France

<sup>2</sup>Department of Microbiology and Alimentary Pharmabiotic Centre, University College Cork, Cork, Ireland

**Background**

*Methanobrevibacter smithii* (*Mb. smithii*) is the predominant methanogen of the human gut microbiota using CO<sub>2</sub> and H<sub>2</sub> (or formate) for methanogenesis. Other gut methanogens utilize methanol (*Methanosphaera stadtmanae*) and methylamines (members of newly identified order Methanomassiliicoccales) by H<sub>2</sub>-dependent methanogenesis.

**Objectives**

Genomic analysis revealed that genes encoding the methanol-utilizing methanogenesis pathway (*mtaABC*) are present in most of the human gut strains of *Mb. smithii*, encompassing the completely sequenced DSMZ 861 strain. This arises the possibility that this methanobacteriale is also able to use methanol as substrate in the gut. This hypothesis was therefore tested.

**Methods**

The reference strain DSMZ 861 (ATCC 35061) was obtained from DSMZ (Braunschweig, Germany) and was cultured in DSM141 media under different conditions regards to H<sub>2</sub>, CO<sub>2</sub> and methanol. Gene expression of *mtaB* and *mcrA* genes (involved respectively in the methanol use and in the final common step of the methanogenesis pathways) were quantitatively evaluated by qPCR.

**Conclusions**

The DSMZ 861 strain originating from the human gut is able to perform methanogenesis with methanol and H<sub>2</sub>. A lower methane production rate was recorded when compared to normal hydrogenotrophic pathway. Methanol induces the expression of the *mtaB* gene while *mcrA* relative expression was lowered. This capability to use methanol coupled with its standard hydrogenotrophic methanogenesis provides a clue to explain the predominance of *Mb. smithii* over other methanogens in the human gut.

**SIGMA54-DEPENDENT REGULATION OF P-ETHYLPHENOL AND P-HYDROXYACETOPHENONE DEGRADATION IN “AROMATOLEUM AROMATICUM” EBN1**

I. Büsing<sup>1</sup>, M. Trinkler<sup>1</sup>, M. Dörries<sup>1</sup>, L. Wöhlbrand<sup>1</sup>, R. Rabus<sup>1</sup>

<sup>1</sup>General and Molecular Microbiology, Universität Oldenburg ICBM, Oldenburg, Germany

**Background**

Anaerobic *p*-ethylphenol and *p*-hydroxyacetophenone degradation in the denitrifying bacterium “*Aromatoleum aromaticum*” EbN1 is predicted to be transcriptionally controlled by the sigma54-dependent regulator EbA324. The latter is encoded in between the two operons comprising genes of *p*-ethylphenol/*p*-hydroxyacetophenone degradation and detoxification.

**Objectives**

Generation of an unmarked, *in-frame* deletion mutant (strain EbN1  $\Delta$ ebA324) to validate EbA324 as mediator of substrate-specific transcriptional activation.

**Methods**

The established genetic system for strain EbN1 was applied to generate deletion mutant strain  $\Delta$ ebA324 and the corresponding complementation strain  $\Delta$ ebA324::*ebA324*. Both mutant strains and the wild type were physiologically analyzed applying *p*-ethylphenol, *p*-hydroxyacetophenone, benzoate or a mixture of benzoate- *p*-hydroxyacetophenone and subsequently studied on the transcript and protein level.

**Conclusions**

The  $\Delta$ ebA324 mutant was unable to grow with both *p*-ethylphenol and *p*-hydroxyacetophenone. Accordingly, no transcripts of the *p*-ethylphenol operons were detected in the  $\Delta$ ebA324 mutant using benzoate as growth promoting co-substrate. In contrast, transcripts and proteins of both operons were detected in the wild type and complemented mutant strain, supporting the proposed function of EbA324. Furthermore, transcriptional activation by EbA324 depends on the presence of either *p*-ethylphenol or *p*-hydroxy-acetophenone: high level constitutive formation of EbA324 in the complemented mutant only yields operon expression in the presence of these compounds.

## **ADAPTATION OF LISTERIA WEIHENSTEPHANENSIS TO ANAEROBIOSIS**

E. Ferrari<sup>1</sup>, S. Scherer<sup>1</sup>, S. Müller-Herbst<sup>1</sup>

<sup>1</sup>Lehrstuhl für Mikrobielle Ökologie,

Wissenschaftszentrum Weihenstephan Technische Universität München, Freising, Germany

### **Background**

*Listeria weihenstephanensis* is a recently new described *Listeria* specie. It was isolated from the water plant *Lemna trisulca* from a fresh water pond in Bavaria, Germany. The isolate is non-haemolytic and has not been associated with animal or human diseases. It has an optimal growth at pH 7-8 and temperature at 28-34 °C. It requires a relative low demand of nutrients and is able to grow under both aerobic and anaerobic conditions.

### **Objectives**

In the present study, the focus was the investigation of the adaptation of *L. weihenstephanensis* to oxygen availability, with respect to the temperature-dependent influence.

### **Methods**

Growth analyses for *L. weihenstephanensis* were performed aerobically and anaerobically in BHI medium at 18 °C and 34 °C. Global transcriptional analyses, via next generation RNA sequencing, were then performed for cells grown aerobically or anaerobically to an OD<sub>600</sub> = 0.85-0.90. The oxygen dependent gene expression of selected genes was further validated via qPCR.

### **Conclusions**

At 18 °C, 49 genes were found to be stronger transcribed aerobically while 40 genes were found to be stronger transcribed anaerobically. At 34 °C, 52 genes exhibited aerobically a stronger transcription while transcription of 27 genes was induced anaerobically. Among the differently regulated genes, many encode for metabolic enzymes indicating broad metabolic adaptations with respect to oxygen availability. Moreover, the transcriptional results clarified that temperature does not play a key role in this oxygen-dependent regulation for *L. weihenstephanensis*.

**C<sub>4</sub>-DICARBOXYLATE TRANSPORT AND GLOBAL TRANSCRIPTOME ANALYSIS OF C<sub>4</sub>-DICARBOXYLATE METABOLISM IN ACTINOBACILLUS SUCCINOGENES**

O. Kim<sup>1</sup>, M. Rhie<sup>1</sup>, I. Cho<sup>2</sup>, H. Ko<sup>2</sup>

<sup>1</sup>Department of Life Science, Ewha Womans University, Seoul, Korea

<sup>2</sup>School of Life Sciences and Biotechnology, Korea University, Seoul, Korea

**Background**

*Actinobacillus succinogenes* that is known to produce large amounts of succinate during hexose fermentation was able to grow on C<sub>4</sub>-dicarboxylates like fumarate under aerobic and anaerobic condition. Succinate was the major product from anaerobic growth on fumarate, similar to growth on glucose. It indicates the involvement of fumarate respiration and the presence of proteins for C<sub>4</sub>-dicarboxylate transport.

**Objectives**

This study aims to characterize transport properties related to C<sub>4</sub>-dicarboxylate metabolism of *A. succinogenes*.

**Methods**

Transport of <sup>14</sup>C-fumarate and <sup>14</sup>C-succinate were studied with bacterial cells of *A. succinogenes* grown on fumarate under anaerobic condition. Transport properties were determined concentration-, time-, pH-dependently or in the presence of ionophores.

Global transcriptome was analyzed by total-RNA-sequencing using MiSeq platform. The total RNAs were isolated from cells grown on fumarate or glucose under aerobic or anaerobic condition.

**Conclusions**

Transport assay revealed that *A. succinogenes* has several transport systems representing specific uptake activities dependent on concentration range of for C<sub>4</sub>-dicarboxylates. Some of them required proton potential, but the others Na<sup>+</sup> gradient.

The genome of *A. succinogenes* possesses candidate genes encoding 18 different transport systems. Global transcriptome analysis showed that six transport systems are expressed during anaerobic growth on fumarate, which includes transporters of the Dcu, DcuC, DASS, and TRAP family.

Overall, *A. succinogenes* could utilize six different protein systems for anaerobic C<sub>4</sub>-dicarboxylates transport, according to availability of driving force and substrate concentration.

## **AN UNUSUAL METHANOGENIC PATHWAY FOUND IN METHANOMASSILIICOCCUS LUMINYENSIS**

L. Kröninger<sup>1</sup>, S. Berger<sup>1</sup>, U. Deppenmeier<sup>1</sup>

<sup>1</sup>Applied Microbiology, Institute for Microbiology and Biotechnology, Bonn, Germany

### **Background**

*Methanomassiliicoccus (Mmc.) luminyensis* is a methanogenic archaeon and was first isolated from human feces. The organism belongs to the recently discovered order of the Methanomassiliicoccales and uses methylated compounds together with H<sub>2</sub> as substrates, which is distinct from other methanogenic pathways.

### **Objectives**

*Mmc. luminyensis* shows unique metabolic features since it combines different methanogenic strategies in the course of heterodisulfide reduction possessing both, a soluble heterodisulfide reductase (HdrABC) and HdrD as compound of the membrane bound heterodisulfide reductase found in members of the order Methanosarcinales. Therefore the heterodisulfide reduction system of *Mmc. luminyensis* is of great scientific interest.

### **Methods**

In a novel approach using quantitative reverse transcriptase PCR we identified key enzymes of the methanogenic pathway of *Mmc. luminyensis*. To further investigate the role of membrane bound enzymes during methanogenesis membranes of *Mmc. luminyensis* were isolated and tested for the oxidation or reduction of artificial electron mediators such as viologen dyes. Additionally enzymes from *Mmc. luminyensis* will be produced heterologously and characterized in order to elucidate the methanogenic metabolism of the organism in detail. A special focus will be placed on the headless F<sub>420</sub>H<sub>2</sub> dehydrogenase (Fpo) complex lacking subunit FpoF, which is essential for F<sub>420</sub>H<sub>2</sub> oxidation, and HdrD since the HdrE subunit of the usually membrane bound heterodisulfide reductase is missing.

### **Conclusions**

If those enzymes are active despite their deficiency of certain key subunits *Mmc. luminyensis* could employ a new methanogenic pathway combining classical enzymes known from other methanogens in a so far not described manner.

**REDUCTIVE DECHLORINATION OF EITHER TETRACHLOROETHENE OR 1,2-DICHLOROETHANE BY DEHALOGENASES WITH SIMILAR PROPERTIES BUT DIFFERENT REACTION MECHANISMS**

C. Kunze<sup>1</sup>, T. Schubert<sup>1</sup>, G. Diekert<sup>1</sup>

<sup>1</sup>Applied and Ecological Microbiology,

Institute of Microbiology Friedrich Schiller University of Jena, Jena, Germany

**Background**

Organohalide respiring bacteria are able to use halogenated organic compounds as terminal electron acceptors for growth. The key enzyme for the conversion of these substrates is the reductive dehalogenase (RDase), a cobamide-containing iron-sulfur protein. Biochemical and structural data showed the cobamide cofactor as the reactive species in the RDase's active site [1]. Numerous RDase protein sequences are listed in databases [2], but only a few enzymes were biochemically characterized. The RDase of *Sulfurospirillum multivorans*, PceA, converts tetrachloroethene via trichloroethene to *cis*-1,2-dichloroethene in a hydrogenolysis reaction [3]. In contrast, the RDase of *Desulfitobacterium dichloroeliminans*, DcaA, catalyzes the formation of ethene from 1,2-dichloroethane by a dihaloelimination mechanism [4].

**Objectives**

The structural determinants in RDases will be identified, which are responsible for the catalysis of either a hydrogenolysis or a dihaloelimination reaction.

**Methods**

In silico structural analysis of DcaA based on the crystal structure of PceA is conducted. The substrate spectrum of recombinant DcaA is determined via enzyme activity measurements. Site-directed mutagenesis is applied to unravel the role of amino acids forming the DcaA's active site.

**Conclusions**

From the results of this study, a better understanding of the diversity in RDase substrate spectra and reaction mechanisms and an improved classification of unknown RDases based on their protein sequence is expected.

## **THE ANAEROBIC LINALOOL METABOLISM OF THAUERA LINALOOLENTIS 47LOL**

R. Marmulla<sup>1</sup>, J. Harder<sup>1</sup>

<sup>1</sup>Microbiology, Max Planck Institute for Marine Microbiology, Bremen, Germany

### **Background**

*Thauera linaloolentis* 47Lol<sup>T</sup> grows on linalool (3,7-dimethylocta-1,6-dien-3-ol), a tertiary monoterpene alcohol, as sole carbon and energy source under denitrifying conditions. Linalool mineralization is initiated by isomerization into the primary alcohol geraniol by a novel enzyme, a linalool isomerase (Foss and Harder, 1997, Foss and Harder, 1998). Geraniol degradation may proceed in analogy to the acyclic terpene utilization (ATU) pathway, as described for various *Pseudomonas* strains (Förster-Fromme and Jendrosseck, 2010). This pathway involves an oxidation of geraniol to geranic acid. After activation by coenzyme A thioester formation, the monoterpene structure is shortened by beta-oxidation, and rearrangement to 3-methylcrotonyl-CoA, ultimately entering the leucine degradation pathway (LIU).

### **Objectives**

The objective of this study was to elucidate the anaerobic linalool metabolism in *Thauera linaloolentis* 47Lol.

### **Methods**

Recently, draft genomes of *T. linaloolentis* 47Lol became available and we detected candidate genes of the ATU and LIU pathways in the genome. Expressed proteins present in linalool-grown cells included many corresponding proteins.

### **Conclusions**

So far, the ATU pathway has only been described in various *Pseudomonas* strains growing aerobically. Our findings are the first observation for the utilization of the ATU pathway under anaerobic conditions.

**FEMS-2183**

**BONCAT TAGGING FOR DIRECT QUANTIFICATION OF RESPIRING AND NON-RESPIRING SUBPOPULATIONS IN PARACOCCLUS DENITRIFICANS DURING TRANSITIONS FROM AEROBIC RESPIRATION TO DENITRIFICATION**

D.A. Milligan<sup>1</sup>, L.L. Bergaust<sup>1</sup>, L.R. Bakken<sup>2</sup>, A. Frostegård<sup>1</sup>

<sup>1</sup>IKBM, Norwegian University of Life Sciences (NMBU), Ås, Norway

<sup>2</sup>IMV, Norwegian University of Life Sciences (NMBU), Ås, Norway

**Background**

Ecophysiological studies have revealed that the regulation of denitrification pathways is highly variable among bacterial strains. One aspect of the regulatory phenotype is the maintenance and distribution of the denitrification proteome within clonal populations. Gas kinetics studies of batch cultures during the transition from aerobic respiration to denitrification have indicated that in many organisms there is a uniform onset of N-oxide reduction amongst cells in the population. Mathematical modelling suggests that the model organism for denitrification studies, *Paracoccus denitrificans*, has a different strategy reminiscent of bet-hedging where only a subset of cells (Fden) start to denitrify, and thus continue to grow, upon oxygen depletion [1].

**Objectives**

We aim to estimate the proportion of cells successfully switching to denitrification by quantifying directly the cells that are showing translational activity after the onset of denitrifying conditions.

**Methods**

The bioorthogonal noncanonical amino acid tagging (BONCAT) approach takes advantage of chemical groups that react with each other at near-physiological conditions, but not with other cell components. These are appended to the bacterial proteome during translation using supplementation of a noncanonical amino acid, in this case azidohomoalanine (AHA). A fluorescent dye displaying a complementary moiety is then used to visualize cells displaying the modified proteins.

**Conclusions**

The BONCAT method was shown to be successful in differentiating between fully respiring cells and those that were inactive, only showing low background fluorescence. Studies are currently undertaken to determine Fden for *P. denitrificans* cultures undergoing the transition from aerobic to denitrifying growth.

## **A NOVEL ANAEROBIC TOLUENE-DEGRADING BACTERIAL STRAIN OF CLOSTRIDIACEAE FROM AN OIL-CONTAMINATED SOIL**

U. Min<sup>1</sup>, S. Kim<sup>1</sup>, H. Hong<sup>1</sup>, J. Gwak<sup>1</sup>, S. Rhee<sup>1</sup>

<sup>1</sup>Microbiology, Chungbuk National University, Cheongju, Korea

### **Background**

Anaerobic degradation of aromatic hydrocarbons is important for bioremediation of contaminated subsurface environments. Information on the microbial diversity and metabolic pathways involved in anaerobic degradation of hydrocarbons is crucial for successful cleanup of hydrocarbons in subsurface. Although members of the family *Clostridiaceae* have been frequently observed in the analysis of various hydrocarbon-contaminated microbial communities, there are limited studies on the biodegradation potential of *Clostridiaceae*.

### **Objectives**

The aims of this study are to isolate hydrocarbon degrading strains of *Clostridiaceae* and elucidate the biochemical and genomic properties of the strain regarding anaerobic biodegradation.

### **Methods**

Enrichment cultures inoculated with various soils from oil spill sites were incubated for several years with petroleum amendment. After enrichment, several colonies were obtained using the roll tube method. Among the isolates, one strain, designated IRF9, was found to degrade toluene and thus selected for further biochemical and genomic analysis.

### **Conclusions**

An alkaliphilic and heterotrophic aromatic hydrocarbon-degrading bacterial strain, IRF9, was isolated from the enrichment cultures. Cells of strain IRF9 were straight or curved rod-shaped, motile, and Gram-negative. Optimal growth of strain IRF9 was observed at pH 9.0–9.5 and 40 °C. The strain was found to grow within pH and temperature ranges of 6.5–10.0 and 25–45 °C, respectively. Ferric iron was used as an electron acceptor but not sulfate, nitrate. The biochemical and genomic studies of the strain IRF9 will shed light on the potential of *Clostridiaceae* for the anaerobic biodegradation of hydrocarbons in subsurface environments.

**HUPO PLAYS IMPORTANT ROLE IN THE REGULATION OF THE HUPSL  
HYDROGENASE OF THIOCAPSA ROSEOPERSICINA**

I.K. Nagy<sup>1</sup>, G. Rákhely<sup>1</sup>, K. Kovács<sup>1</sup>, G. Maróti<sup>2</sup>

<sup>1</sup>Biotechnology, University of Szeged, Szeged, Hungary

<sup>2</sup>Biochemistry, Biological Research Centre Szeged, Szeged, Hungary

**Background**

The photosynthetic purple sulphur bacterium, *Thiocapsa roseopersicina* harbours four functional [NiFe] hydrogenases. Two of them are attached to the periplasmic membrane (HynSL, HupSL) and the other two are localized in the cytoplasm (Hox1, Hox2). It prefers to utilize reduced sulphur compounds for anaerobic phototrophic growth.

**Objectives**

HupSL is a hydrogen uptake hydrogenase which can recycle hydrogen in the environment and provides energy for the cells. The gene expression and enzyme activity correlate with the applied thiosulphate concentration, HupSL shows increased hydrogen uptake activity under low sodium-thiosulphate concentration. The hydrogenase small and large subunits are encoded by the *hupS* and *hupL* genes in the *hupSLCDHIOR* operon. The function of *hupO* gene and its product was completely unknown. In order to investigate the physiological role of the HupO, the *hupO* gene was inactivated by in-frame deletion mutagenesis. The *hupO* gene was deleted in the  $\Delta hynSL$ ,  $\Delta hox1H$ ,  $\Delta hox2H$  (GB113141) mutant (resulting strain HOD134). The effects of the mutation were analyzed by activity and expression measurements.

**Methods**

The *in vivo* activity of the HupSL hydrogenase in the HOD134 strain substantially increased under low sodium thiosulphate concentration compared to the wild-type and complemented strains. These activity measurements were supported by Western analyses and gene expression studies.

**Conclusions**

This study adds to the clarification of the so far unresolved HupSL regulation. The HupO plays a crucial role in this regulation at least under low thiosulphate conditions, where the masking effect of thiosulphate is avoided.

**EFFECT OF CARBON DIOXIDE ON EXOPOLYSACCHARIDE PRODUCTION AND SURVIVAL OF BIFIDOBACTERIUM BIFIDUM AFTER FREEZE-DRYING**

H.T. NGUYEN<sup>1</sup>, F. THONART<sup>1</sup>, F. DELVIGNE<sup>1</sup>

<sup>1</sup>Chemistry and Bio-industries, Gembloux Agro-biotech, Gembloux, Belgium

**Background**

*Bifidobacteria* are particularly sensitive to dissolved oxygen potentially present in bioreactor during the production process [1]. However, oxygen stripping by another gas (i.e., nitrogen and hydrogen) decreases the oxido-reductive potential and improved survival of *B. bifidum* during storage [2]. It is noted that carbon dioxide can not only maintain the anaerobic growth conditions of *Bifidobacterium longum* JBL05 but also enhance the cell concentrations and the exopolysaccharide (EPS) secretion [1]. Moreover, EPS was known to be an important factor for the protection of *B. bifidum* during freeze-drying [3].

**Objectives**

Optimization of oxygen stripping by using different gases (i.e., CO<sub>2</sub> and N<sub>2</sub>) to reduce the redox potential in *B. bifidum* THT0101 culture aimed at (i) improving the survival of cells during freeze-drying and (ii) increasing the EPS secretion during the fermentation.

**Methods**

*B. bifidum* THT0101 was cultured following different degassing procedures. After culturing and freeze-drying, the concentration of exopolysaccharide and the viability of *B. bifidum* THT0101 were evaluated.

The results pointed out a significant increase of viability (5.06-15.6 folds by comparison with controls) in relation with the duration of degassing by CO<sub>2</sub>. Besides, the CO<sub>2</sub> treatments led to a decrease of the redox potential. The concentration of exopolysaccharide increased related to the flow rate of CO<sub>2</sub> and *B. bifidum* THT 0101 survival.

**Conclusions**

The flow rate of CO<sub>2</sub> in culture led to the increase of exopolysaccharide concentration and *B. bifidum* THT0101 survival.

**TRANSPOSON MUTANTS AFFECTING THE METABOLISM OF BICYCLIC MONOTERPENES IN *C. DEFRAGANS* 65PHEN**

E. Puentes Cala<sup>1</sup>, J. Harder<sup>1</sup>

<sup>1</sup>Microbiology, Max Planck Institute for Marine Microbiology, Bremen, Germany

**Background**

Terpenes are natural hydrocarbons mainly produced by plants. Monoterpenes are released to the environment in teragram amounts every year. *Castellaniella defragans* 65Phen, a betaproteobacterium able to grow under denitrifying conditions, uses several aliphatic and cyclic monoterpenes as sole carbon and energy sources (1). This metabolic capability is currently studied intensively and the genome has recently been described (2).

**Objectives**

Identify genes and proteins relevant to the metabolism of the bicyclic monoterpenes 3-carene, sabinene and alpha-pinene.

**Methods**

Random transposon mutagenesis and differential proteomics were used.

**Conclusions**

Firstly, in our study the bicyclic monoterpenes 3-carene, sabinene and alpha-pinene seemed to be isomerized to monocyclic monoterpenes and then further degraded by proteins encoded in a 70 kb genetic island (2). The nucleotide composition of the island is indicative for horizontal gene transfer from several other hydrocarbon degraders to *C. defragans* 65Phen (2). Beta-oxidation of perillic acid and the leucine/isovalerate (liu) pathway were also involved in the metabolic steps of all monoterpenes under investigation. Additionally, several permeases and stress-response proteins had a relevant role in the survival and growth of *C. defragans* 65Phen on monoterpenes, most likely due to the monoterpenes toxicity.

<sup>2</sup>Laboratory of Systems and Synthetic Biology, Wageningen University, Wageningen, Netherlands

<sup>3</sup>School of Biological Sciences, University of Wales, Bangor, United Kingdom

<sup>4</sup>Laboratory of Microbiology, Wageningen University, Wageningen, Netherlands

**Background**

Generally, sulfate-reducing bacteria (SRB) grow optimally at neutral pH but sulfate reduction at low pH has been reported in both natural and engineered environments. Despite evidence of their activity *in situ*, acidophilic SRB have been difficult to isolate and cultivate *in vitro*, possibly due to the inhibitory effect at low pH of metabolites such as sulfide or acetic acid. Thus far, only three species have been formally described: *Desulfosporosinus acidiphilus*, *D. acididurans* and *Thermodesulfobium narugense*.

**Objectives**

Our objective was to isolate novel acidophilic SRB to study their ecophysiology.

**Methods**

Enrichments were set up using sediments from an acid rock drainage environment (Tinto River) and several isolation methods were applied (enrichment, serial dilution and pasteurization).

**Conclusions**

The isolate, strain I, represents a novel lineage of SRB within the *Firmicutes* phylum, proposed as *Desulfobacillus* spp. (93% similarity with the genera *Desulfosporosinus* and *Desulfitobacterium*). The genome-guided characterization shows a very versatile metabolism; it is able to use multiple electron donors and electron acceptors for respiratory growth, and to perform fermentation and disproportionation. Strain I shows a unique metabolism compared to other acidophilic SRB by being able to oxidize acetic acid. As a consequence, strain I is the most acidophilic strain described so far, able to grow while reducing sulfate at a pH as low as 3.8 (optimum at pH 5).

Its high tolerance to low pH and its acetate detoxifying metabolism together with the alkalinity generation coupled to growth of SRB suggest its important role in promoting microbial niches with milder conditions in acidic environments.

## **CONVERSION OF CIS-2-CARBOXYCYCLOHEXYLACETIC ACID IN THE DOWN-STREAM PATHWAY OF ANAEROBIC NAPHTHALENE DEGRADATION**

P. Weyrauch<sup>1</sup>, R.U. Meckenstock<sup>2</sup>

<sup>1</sup>*Institute of Groundwater Ecology, Helmholtz Zentrum Munich, Munich Neuherberg, Germany*

<sup>2</sup>*Biofilm Centre – Institute of Aquatic Microbiology, University of Duisburg-Essen, Essen, Germany*

### **Background**

The ability of anaerobic naphthalene degradation has been demonstrated for the *deltaproteobacterial* strains N47 and NaphS2 under sulfate-reducing conditions (Galushko *et al.*, 1999, Meckenstock *et al.*, 2000). It was shown recently that after carboxylation to 2-naphthoic acid (Moultaki *et al.*, 2012) and formation of the corresponding CoA-ester, the latter is stepwise reduced to a hexahydro-2-naphthoyl-CoA with unknown conformation of the remaining double bonds (Eberlein *et al.*, 2013). Furthermore, *cis*-2-carboxycyclohexylacetic acid could be identified as a metabolite of the down-stream pathway (Annweiler *et al.*, 2002).

### **Objectives**

Our aim for this study was the elucidation of the next metabolites of the pathway following *cis*-2-carboxycyclohexylacetyl-CoA and the identification of the enzyme reactions finally leading to the second ring-cleavage.

### **Methods**

The metabolite *cis*-2-carboxycyclohexylacetic acid was chemically synthesised and converted to the corresponding coenzyme A thioester. The latter was tested for conversion in cell-free-extracts of N47 and NaphS2 in the presence of different potential co-factors and electron acceptors. Samples were analysed by HPLC and emerging metabolites were further characterised via GC-MS.

### **Conclusions**

Conversion of *cis*-2-carboxycyclohexylacetyl-CoA was only observed in the presence of ferrocenium hexafluorophosphate, which can oxidise enzyme-bound co-factors like FADH<sub>2</sub>. The first emerging metabolite had a double-bond introduced, indicating the activity of a FAD-dependent acyl-CoA dehydrogenase. Also the product of the next enzyme, probably a hydratase, could be detected. Combining these data, we can for the first time make a detailed proposal for the steps leading to the second ring-cleavage in the down-stream pathway of anaerobic naphthalene degradation.

**EXPLORING A RICE STRAW DEGRADING MICROBIAL COMMUNITY ENRICHED FROM SWINE MANURE DIGESTER MATERIAL**

*P. Worm<sup>1</sup>, T. Janssens<sup>2</sup>, A.H. van Gelder<sup>1</sup>, Z. Szabo<sup>3</sup>, H. Smidt<sup>1</sup>, A.J.M. Stams<sup>1</sup>*

<sup>1</sup>*Laboratory of Microbiology, Wageningen University, Wageningen, Netherlands*

<sup>2</sup>*, MicroLife Solutions BV, Amsterdam, Netherlands*

<sup>3</sup>*, MicroDish BV, Utrecht, Netherlands*

**Background**

Rice straw is one of the most abundant agricultural waste residues in the world. Currently it is burned in the fields, which causes pollution and greenhouse gas emission, whereas it has potential as feed for biogas production.

**Objectives**

To understand and stimulate biogas production from rice straw, we aim to isolate novel microbes with metabolic capacities that are key in the degradation of rice straw. Ingham et al. (2007) developed the MicroDish Culture Chip (MDCC) for cultivation of micro-colonies.

**Methods**

We set up a method for using the MDCC in anaerobic conditions which allows for screening key capacities and studying microbial interactions.

**Conclusions**

After five weeks incubation of anaerobic liquid cultures at 37°C, 75-80% of the rice straw dry weight was degraded and 250 L\*kg VS<sup>-1</sup> methane was formed, and acetate, propionate, benzoate and 3-phenyl propionate were measured as intermediates. The rice straw-degrading community was recently transferred to specific substrates. After 25 days of incubation methane was formed from cellulose and xylan, but not from lignin.

#### GENE THERAPY PLASMID pORF-hIL12 TRANSFORMATION FREQUENCY AND EFFICIENCY INTO SELECTED BACTERIAL STRAINS: A RISK ASSESSMENT OF AMPICILLIN RESISTANCE GENE TRANSFER

J. Ambrozic Avgustin<sup>1</sup>, G. Sersa<sup>2</sup>, D. Medvescek<sup>3</sup>, A. Krhac Levacic<sup>3</sup>, D. Pavlin<sup>4</sup>, N. Tozon<sup>4</sup>, M. Cemazar<sup>2</sup>, M. Cemazar<sup>5</sup>

<sup>1</sup>Biology, University of Ljubljana Biotechnical Faculty, Ljubljana, Slovenia

<sup>2</sup>Department of Experimental Oncology, Institute of Oncology, Ljubljana, Slovenia

<sup>3</sup>Department of Biology, University of Ljubljana Biotechnical Faculty, Ljubljana, Slovenia

<sup>4</sup>Clinic for small animals and surgery, University of Ljubljana Veterinary Faculty, Ljubljana, Slovenia

<sup>5</sup>Faculty of Health Sciences, University of Primorska, Izola, Slovenia

#### Background

Plasmid gene delivery vectors offer several advantages over viral vectors, including safety, lower toxicity and easier preparation. Selective marker genes coding for antibiotic resistance have been traditionally an essential part of these plasmids. However, health authorities recommended the use of plasmids without resistance markers in order to prevent the spread of resistance genes.

#### Objectives

The aim of our study was to determine the possibility, frequency and efficiency of therapeutic plasmid pORF-hIL12 Amp<sup>R</sup> transformation into different bacterial strains.

#### Methods

The strains used were selected from 69 isolates belonging to 17 genera, which were isolated from dogs skin before application of electrogene therapy (EGT) (1) and from 89 isolates belonging to 17 genera retrieved after EGT. Several enterobacterial strains were also included into the study. Transformation of electrocompetent bacteria from genera *Staphylococcus*, *Bacillus*, *Acinetobacter*, *Kocuria*, *Micrococcus*, *Rhodococcus*, *Streptomyces*, *Mycobacterium* and *Arthrobacter* yielded no transformants with pORF-hIL12. The transformation frequency (efficiency) of *Escherichia coli*, *E. hermanii*, *Buttiauxella* sp., *Salmonella enterica*, *Proteus vulgaris*, *Erwinia chrysanthemii*, *Yersinia* sp., *Providencia* sp., *Enterobacter* sp., *Shigella boydii*, *Herbaspirillum frisingense* and *Sfingomonas* sp. ranged between 10<sup>-4</sup> and 10<sup>-10</sup> (10<sup>-1</sup> and 10<sup>-5</sup>).

#### Conclusions

Our study revealed that pORF-hIL12 could be introduced into several enterobacterial species, if they are present on the dogs skin and naturally competent. Thus a potential risk for the spread of the ampicillin resistance gene from pORF-hIL12 by horizontal gene transfer can not be excluded.

## **IN VITRO SUSCEPTIBILITY ACTIVITIES OF EIGHT ANTIFUNGAL DRUGS AGAINST CLINICAL AND ENVIRONMENTAL ISOLATES OF PHAEOACREMONIUM SPECIES**

H. Badali<sup>1</sup>, M. Jacques F.<sup>2</sup>

<sup>1</sup>Department of Medical Mycology,  
Invasive Fungi Research Center Mazandaran University of Medical Sciences, Sari,  
Iran

<sup>2</sup>Department of Medical Microbiology and Infectious Diseases,  
Canisius Wilhelmina Hospital The Netherlands, Nijmegen, Netherlands

### **Background**

Phaeoacremonium species are chiefly found in the environment and can either cause a plant disease which is an uncommon cause of human disease. Most cases of Phaeoacremonium infection in humans involve traumatic inoculation and present as subcutaneous abscesses, cysts, or osteoarthritis. The spectrum of disease caused by Phaeoacremonium species especially *P. parasiticum* is variable and ranges from subcutaneous infections to eumycetoma, arthritis, osteomyelitis, endocarditis, fungemia and disseminated disease.

### **Objectives**

Despite worrying clinical pictures associated with *Phaeoacremonium*, there is little information regarding the antifungal susceptibility patterns against currently available antifungal agents.

### **Methods**

Thus, the *in vitro* activities of eight antifungal agents against clinical and environmental strains of *Phaeoacremonium* were obtained. The Clinical and Laboratory Standards Institute (CLSI) provides no specific guidelines for testing the *in vitro* antifungal susceptibility of this fungus. No other testing protocol has also been validated for testing the susceptibility of *Phaeoacremonium*.

### **Conclusions**

In the present study, the resulting MIC<sub>90</sub>s for all strains were as follows, in increasing order: POS (0.125 µg/ml; VOR (0.5 µg/ml); AmB (0.5 µg/ml); ISA (1 µg/ml); CAS (8 µg/ml); ANID (8 µg/ml); ITC (16 µg/ml); and FLU (64 µg/ml). The difference in the MIC<sub>90</sub>s between the two groups of isolates did not differ by more than one

dilution. Therefore, the present study based on *in vitro* activity showed that posaconazole and voriconazole might have a potent activity with a best choice of alternative to amphotericin B. In

**IMPACT OF WASTEWATER DISCHARGES IN SOILS: DEFINITION OF LIMITS OF DETECTION AND QUANTIFICATION OF ANTIBIOTIC RESISTANCE GENES**

C. Becerra-Castro<sup>1</sup>, S. Teixeira<sup>2</sup>, O.C. Nunes<sup>2</sup>, C.M. Manaia<sup>1</sup>

<sup>1</sup>CBQF – Centro de Biotecnologia e Química Fina,

Escola Superior de Biotecnologia Universidade Católica Portuguesa, Porto, Portugal

<sup>2</sup>LEPABE Laboratório de Engenharia de Processos Ambiente Biotecnologia e Energia, Faculdade de Engenharia Universidade do Porto, Porto, Portugal

**Background**

Wastewater can contribute to the spread of antibiotic resistant bacteria and resistance genes (ARB&G) in the environment. The discharge of treated wastewater in soils may lead to the accumulation of different contaminants, including ARB&G. However, due to technical limitations and low abundance of ARB&G in water, it is possible that the effects remain unnoticed before a long term exposure has occurred.

**Objectives**

To test this hypothesis, we designed an experiment to assess the limits of detection of ARG in soil.

**Methods**

An agricultural soil was soaked with a synthetic effluent containing two ARB to reach bacterial densities from  $10^2$  up to  $10^9$  CFU/g. ARB were *Escherichia coli* strain A2FCC14, which harbours the genes *bla*TEM, *bla*CTX-M-15, *bla*OXA-1, *aac*(6')-Ib-cr and integrase Intl-1, and *Enterococcus faecalis* H1EV10, with the *vanA* gene.

ARB&G detection limits were assessed based on culture-dependent and culture-independent methods (PCR and qPCR).

**Conclusions**

The limit of detection by conventional PCR was gene-dependent and corresponded to bacterial densities between  $10^4$  (in the case of *aac*(6')-Ib-cr) and  $10^7$  CFU/g soil (in the case of *bla*CTX-M-15 and *bla*OXA-1). Using qPCR, the quantification limit corresponded to bacterial densities of  $10^3$  CFU/g soil, although detection was possible for lower genes abundances. However, these values can be considered high for certain up to now uncommon ARG, which can spread in soils remaining unnoticed. The relatively high detection limits observed will be discussed, highlighting the meaning of this shortcoming for an adequate risk assessment of the implications of wastewater discharges in soil.

### **Background**

Evolution of bacterial antibiotic resistance represents one of the most threatening health care problems worldwide. This problem urgently requires a better understanding of important reservoirs and paths of dissemination, such as those represented by wastewater treatment and reuse.

### **Objectives**

While coordinated European Surveillance programs exist for clinically-associated antibiotic resistance, equivalent programs addressing the (aquatic) environments are missing. The aim of this study was to obtain a first insight into the abundance of antibiotic resistance genes in the treated effluent discharged by urban wastewater treatment plants (UWTP) from distinct geographic areas. This is the first pan-European synopsis on the levels of antibiotic resistance genes in treated wastewater.

## **Methods**

Within the 2014 WG5 Norman campaign we screened 20 (UWTP) in 13 different nations in Europe to screen for five environmentally and medically relevant antibiotic resistance and related genes (ARG, blaTEM; vanA; qnrS; sul1; ctx-m 32 and intl1). For three consecutive days, 24h-composite samples were collected and processed immediately for DNA extraction.

## **Conclusions**

All analysed ARG were detected in samples from all countries, with differences between different UWTP effluents, suggesting that the investigated determinants are adequate indicators. A north to south gradient within Europe could be observed, with the northern UWTPs showing the lower abundance of ARGs in the effluent than southern countries. This study sets the base for further studies investigating correlations between resistances and treatment processes, and linking environmental and clinical occurrence.

**VIROME-ASSOCIATED ANTIBIOTIC RESISTANCE GENES IN FRESHWATER  
AQUACULTURE**

S. Colombo<sup>1</sup>, S. Arioli<sup>1</sup>, S. Guglielmetti<sup>1</sup>, F. Lunelli<sup>2</sup>, D. Mora<sup>1</sup>

<sup>1</sup>*Department of Food Environmental and Nutritional Sciences (DeFENS),  
University of Milan, Milan, Italy*

<sup>2</sup>*Unità Acquacultura e Idrobiologia, Fondazione Edmund Mach,  
San Michele All'Adige, Italy*

**Background**

Due to their structural characteristics in extracellular phase, bacteriophages persist quite successfully in the environment and are resistant to natural or man generated stressors. Aquatic compartments may therefore play a significant role in driving antibiotic resistance genes (ARGs) transfer.

**Objectives**

The project is aimed to highlight the impact of viral populations in the spreading of ARGs in aquaculture.

**Methods**

Upstream and downstream water samples from an experimental salmonid aquaculture were treated with a tangential flow filtration system to separate and concentrate viral-like particles and microbial cells. Then viromes were investigated through shotgun NGS while DNA from microbial communities underwent NGS 16S *rRNA* gene profiling. Bioinformatic analysis was performed using QIIME and Meta-Vir tools, CARD, NCBI, and COG database. The AR colonies frequency was evaluated by standard plating.

## **Conclusions**

Upstream and downstream samples were characterized by limited changes in viral community composition at family level, while a large variation in bacterial population was observed. The relative abundance of AR drug classes did not significantly change whereas the taxonomic distribution of ARGs and bacterial metabolic genes in the viromes were remarkably different between upstream and downstream samples thereby reflecting the taxonomic composition and diversity of the bacterial communities. Interestingly, an inverse relationship between the relative abundance of genes belonging to a bacterial family in the virome and the same bacterial family abundance in the microbioma was observed. Furthermore, the frequency of AR resistant colonies showed an inverse relationship with respect to the abundance of specific virome-associated ARGs.

**CHARACTERIZATION OF YBJG, A PYROPHOSPHATE PHOSPHATASE FROM *E. COLI* INVOLVED IN THE LIPID CARRIER UNDECAPRENYL PHOSPHATE METABOLISM**

*F. Delbrassine*<sup>1</sup>, *R. Auger*<sup>2</sup>, *M. EL GHACHI*<sup>1</sup>, *A. LAMBION*<sup>1</sup>, *T. TOUZÉ*<sup>2</sup>, *G. MANAT*<sup>2</sup>, *F. KERFF*<sup>1</sup>

<sup>1</sup>*Cristallographie des macromolécules biologiques, University of Liège, Liège, Belgium*

<sup>2</sup>*Institut de Biochimie et Biophysique Moléculaire et Cellulaire (EBA-IBBMC), Université Paris-Sud, Paris, France*

**Background**

Undecaprenyl phosphate (C<sub>55</sub>-P) is an essential lipid carrier involved in the biosynthesis of cell surface carbohydrate polymers such as the peptidoglycan. C<sub>55</sub>-P is the result of the dephosphorylation of the undecaprenyl pyrophosphate (C<sub>55</sub>-PP) by specific phosphatases. In *Escherichia coli* this dephosphorylation can be performed by four integral membrane proteins, BacA, and three members of the type 2 phosphatidic acid phosphatase family (PAP2), PgpB, YbjG, and LpxT.

**Objectives**

The aim of this project is to characterize YbjG and contributes to the understanding of the physiological role and mechanism of action of this enzyme in the C<sub>55</sub>-P metabolism. The C<sub>55</sub>-PP phosphatases could become an interesting target in the search for new molecules with antibacterial activity.

**Methods**

In parallel the stability of YbjG and its activity against C<sub>15</sub>-PP were assessed in 94 different detergents. Moreover the enzymatic activity of YbjG was studied: substrate specificity, optimum pH and temperature, effect of detergent concentration.

**Conclusions**

For the first time, YbjG has been purified and we show its ability to dephosphorylate C<sub>15</sub>-PP, DGPP and C<sub>55</sub>-PP *in vitro* with respectively decreasing efficiency. No activity has been detected on five other potential substrates (PPi, PA, C<sub>5</sub>-PP, G6P & PNPP).

The phosphatase activity on C<sub>15</sub>-PP is maximum at pH 6,5 and 25 °C. Moreover Cymal6, LMNG, & ωUDM are good detergent both for the stability and the C<sub>15</sub>-PP

phosphatase activity of YbjG, but approximately half of the 94 tested detergents show C<sub>15</sub>-PP phosphatase activity on the qualitative enzymatic test.

**Antibiotic resistance and environment**

**CONSTITUTIVE PRESENCE OF ANTIBIOTIC RESISTANCE GENES WITHIN THE BACTERIAL COMMUNITY OF A LARGE SUBALPINE LAKE**

A. Di Cesare<sup>1</sup>, E.M. Eckert<sup>1</sup>, G. Corno<sup>1</sup>

<sup>1</sup>ISE-MEG, CNR-National Research Council of Italy, Verbania, Italy

**Background**

The fate of antibiotic resistance genes (ARGs) in natural bacterial communities is of primary concern as prodromal of their potential spread within pathogenic bacteria. Although of diverse origin, the persistence of ARGs in aquatic environments is highly influenced by anthropic activities, allowing potential control actions in well-studied environments. However, knowledge of their abundance and dynamics in ecosystems is still scarce.

**Objectives**

We investigated the presence and the abundance of twelve ARGs in large, subalpine Lake Maggiore (Italy/Switzerland), using qPCR, at different stations, depths and seasons. In order to compare seasonal dynamics to short-term changes we sampled one station daily over the course of a week. We then evaluated correlations between ARGs and the bacterial community composition assessed with Illumina sequencing of the 16S rDNA and a number of environmental parameters, including bacterial density, temperature, chlorophyll, oxygen and water transparency.

**Methods**

**Conclusions**

Our results suggest the constitutive presence of at least three to four ARGs within the natural bacterial community, with a high proportion of bacteria potentially resistant to tetracyclines and sulphonamides. However, in some cases we also observed short-lived peaks of ARGs (one day) which also co-occurred with a significant change of the bacterial diversity in the system. These observations, on the one hand propose the lake as an ideal reservoir for the persistence of certain ARGs, and on the other hand it suffers from point pollution with ARGs. This highlights the need for an appropriate management of the antibiotic consumption in the catchment basin and of the potential sources of contamination.

### **Antibiotic resistance and environment**

#### **ANTIBIOTIC RESISTANCE OF BACTERIAL STRAINS ISOLATED FROM THE AIR OF SORTING FACILITIES**

A.F. Calheiros<sup>1</sup>, V. Monteiro<sup>1</sup>, J. Guerreiro<sup>1</sup>, C. Ramos<sup>1</sup>, P. Fernandes<sup>1</sup>

<sup>1</sup>*Escola Superior de Tecnologia e Gestão, Instituto Politécnico de Viana do Castelo, Viana do Castelo, Portugal*

#### **Background**

The spread of resistant strains of bacteria in the community is recognized as a recent trend, and this fact adds new risk factors usually not taken into consideration in particular for professional activities where the exposure to biological agents is larger than usual, as is the case of waste sorting facilities.

#### **Objectives**

The study focuses on the characterization of the antibiotic resistance profile of *Staphylococcus* spp. and presumptive *Enterobacteriaceae* strains isolated from the air of sorting facilities.

#### **Methods**

A total of 49 *Staphylococcus* spp. strains isolated from air samples were used for the detection of *mecA* and *pvl* genes by RT-PCR. Phenotypic resistance has been determined by disk diffusion and agar dilution methods. From an initial screening of 133 air samples using McConkey agar containing meropenem (2mg/L), 37 Gram (-) strains were phenotypically characterized. Strains resistant to meropenem were characterized in terms of resistance to other 15 antibiotics of 7 different classes using the disk diffusion method.

#### **Conclusions**

None of the *Staphylococcus* spp. strains was *pvl* (+). The presence of the gene *mecA* was observed in 8% of the *Staphylococcus* spp. strains tested and 25 of the strains were able to grow in the presence of oxacillin concentrations between 0,5 mg/L and 4 mg/L. The presumptive *Enterobacteriaceae* strains isolated in the initial screening showed high prevalence of resistance to at least one antibiotic (95%) and 43% of the strains were resistant to 6 different antibiotics. Meropenem resistance was confirmed in 51% of the strains.

**Antibiotic resistance and environment**

**EXTENDED SPECTRUM BETA-LACTAMASE PRODUCING  
ENTEROBACTERIACEAE IN RECREATIONAL RIVER WATERS OF THE NORTH  
OF PORTUGAL**

M. Pinto<sup>1</sup>, J. Palmeira<sup>1</sup>, D. Gonçalves<sup>1</sup>, H. Ferreira<sup>1</sup>

<sup>1</sup>Microbiology, University of Porto-Pharmacy Faculty, Porto, Portugal

**Background**

River water is one of the most important reservoir and vehicle of bacterial resistance dissemination, in nature. The overexposure of aquatic environments to human and animal intestinal commensals and pathogens, and the selective pressure exerted by factors as antibiotic residues, are important sources of resistance. Our previous work showed multi-resistant ESBL producing *E.coli*, in river water in Portugal, leading us to improve our research about this public health concern.

**Objectives**

Our aim was the detection of ESBL and carbapenemase producing Enterobacteriaceae in recreational river waters in the North of Portugal.

**Methods**

Water samples of 5 different rivers with recreational activities, were analysed by membrane filtration on MacConkey agar and MacConkey Agar with cefotaxime, ciprofloxacin and meropenem. Representatives of different colony morphotypes were tested for antimicrobial susceptibility and carbapenemase screening, according to CLSI and EUCAST. ESBL producers were confirmed by the double-disk-synergy-test and PCR was performed for detection of *bla*<sub>TEM</sub>, *bla*<sub>OXA</sub>, *bla*<sub>SHV</sub>, *bla*<sub>CTX-M-group-1</sub> and *aac(6')-Ib-cr* genes. Isolates were identified by ID-32-GN.

**Conclusions**

Our study showed the dissemination of *bla*<sub>CTX-M-group-1</sub> producing Enterobacteriaceae in this aquatic environment and the presence of Gram-negative-non-fermentative bacteria with reduced susceptibility to carbapenems. From 56 isolates analyzed, 33 showed multi-resistance, 17 were ESBL producers. Isolates of *Escherichia coli*, *Klebsiella pneumoniae* and *Enterobacter* spp. showed positive for *bla*<sub>CTX-M-group-1</sub> (13), *bla*<sub>OXA</sub> (12), *bla*<sub>TEM</sub> (1), *bla*<sub>SHV</sub> (6) and *aac(6')-Ib-cr* (1), genes. Results indicate that recreational river waters of the North of Portugal are reservoirs of ESBL producing Enterobacteriaceae and non-fermentative-Gram-negatives with reduced susceptibility to carbapenems, suggesting a public health concern.

#### **CATTLE AS RESERVOIR OF CIPROFLOXACIN RESISTANT COLIFORMS**

*T. Vilaça*<sup>1</sup>, *D. Gonçalves*<sup>1</sup>, *H. Ferreira*<sup>2</sup>

<sup>1</sup>*Microbiology, University of Porto-Pharmacy Faculty, Porto, Portugal*

<sup>2</sup>*Microbiology, University of Porto-Pharmacy Faculty-REQUIMTE, Porto, Portugal*

#### **Background**

Human intestinal colonization by antimicrobial resistant *E.coli*, suggests environmental reservoirs as water, food or direct contact with animals. Descriptions of fecal carriage in food-producing animals, might suggest cross-transmission between humans and animals or a common environmental source. Meat can be a source of resistant bacteria that can spread through the food chain.

#### **Objectives**

The aim of our study was the detection of ciprofloxacin resistant (CR) coliforms in cattle fecal flora of two different type facilities in the North of Portugal.

#### **Methods**

Faecal samples were suspended in TSB and incubated at 37°C overnight. Isolates were selected on MacConkey agar with and without ciprofloxacin. Colonies of lactose fermenters were randomly selected and susceptibility to antimicrobial agents was determined by the agar diffusion test using CLSI guidelines. Strains were identified by ID 32 GN and API 20 E. Genetic information was investigated for *qnr* and *aac(6')-Ib-cr* genes, by PCR.

#### **Conclusions**

Our study showed the emergence of *qnrA* and *aac(6')Ib-cr* mediated ciprofloxacin resistance in coliforms from Portuguese cattle. CR *E.coli* isolates were detected in all samples of intensive production. ESBL producers were detected among the CR isolates, and resistance to tetracycline, chloramphenicol, trimethoprim-sulfamethoxazole,  $\beta$ -lactams and  $\beta$ -lactam/inhibitor association, was frequent.

Intestinal flora of cattle might act as reservoir of CR coliforms. Fluoroquinolones used in veterinary suggest a potential for selection of CR coliforms in the faecal flora of

production animals. Bovines can be a source of resistant bacteria colonization through the food chain, by unexpected contamination of carcasses by CR fecal isolates.

#### **ACQUIRED PLASMIDS HAVE A ROLE IN THE FITNESS AND PHENOTIPIC CHARACTERISTICS OF BACTERIA**

O. Garaiyurrebaso<sup>1</sup>, E. Grohmann<sup>2</sup>, F.M. Goñi<sup>1</sup>, F. Blanco<sup>3</sup>, L. Epelde<sup>3</sup>, C. Garbisu<sup>3</sup>, I. Alkorta<sup>1</sup>

<sup>1</sup>*Unidad de Biofísica CSIC-UPV/EHU, and Department of Biochemistry and Molecular Biology, Science and Technology Faculty, University of the Basque Country, Spain*

<sup>2</sup>*University Medical Centre Freiburg, Division of Infectious Diseases, Freiburg, Germany*

<sup>3</sup>*NEIKER-Tecnalia, Soil Microbial Ecology Group, Derio, Spain*

**Background** The spread of antibiotic resistance among bacteria has become one of the most important health problems nowadays. The problem relays on the dissemination of antibiotic resistance genes by conjugative plasmids. Increasing antibiotic concentrations in clinical and natural environments enhances this problem. Many antibacterial compounds have their roots in natural environments, such as soil. As a consequence, bacteria have coevolved and shared resistance mechanisms and genes along evolution.

**Objectives** This work is focused on the search of new conjugative plasmids from environmental unique soils in which high concentrations of antibiotics are present as a result of animal manure amendments. Additionally, we aim to study the effect of these plasmids on the fitness and phenotype of recipient bacteria.

**Methods** Exogenous Plasmid Isolation technique was used to collect conjugative plasmids from the bacterial community present in different soils. We obtained a total of 17 *E. coli* transconjugants from 10 different soils selected with ampicillin, erythromycin, chloramphenicol or streptomycin. To study the effect that the acquisition of these plasmids has on the fitness and phenotype of *E. coli* transconjugants, we determined growth curves, antibiotic MIC values, and community-level physiological profiles (BIOLOGTM) which provide information on carbon substrate utilization patterns.

**Conclusions** We conclude that acquired conjugative plasmids affect both fitness and phenotype of recipient bacteria.

#### **EXTRAINTESTINAL PATHOGENIC ESCHERICHIA COLI SEQUENCE TYPE 131 IN HEALTHY BROILER CHICKEN MEAT IN ITALY: A COMBINATION OF ANTIBIOTIC RESISTANCE WITH VIRULENCE**

*A. Ghodous*<sup>1</sup>, *C. Bunora*<sup>2</sup>, *A.M. Di Noto*<sup>3</sup>, *C. Mammina*<sup>2</sup>

<sup>1</sup>1.PhD School in Molecular Medicine <sup>2</sup>2.Department of Sciences for Health Promotion and Mother-Child Care "G. D'Alessandro", Università degli Studi di Palermo, Palermo, Italy

<sup>2</sup>Department of Sciences for Health Promotion and Mother-Child Care "G. D'Alessandro", Università degli Studi di Palermo, Palermo, Italy

<sup>3</sup>Experimental Zooprophyllactic Institute of Sicily "A. Mirri", Università degli Studi di Palermo, Palermo, Italy

#### **Background**

Extraintestinal pathogenic *Escherichia coli* sequence type 131 (ExPEC-ST131) has emerged internationally as a multidrug-resistant pathogen. It has been shown that the transmission can occur from animals to humans. Based on existing evidence, poultry is the food animal source most closely linked to human *E. coli*.

#### **Objectives**

The objective was to characterize ExPEC from raw chicken meats purchased from Palermo, Italy.

#### **Methods**

In a total of 187 raw chicken meat from retail markets in Palermo, Italy during March-November 2014, selective cultures and disk-diffusion assays for the isolation and characterization of antimicrobial-resistant *E. coli* were performed. Polymerase chain reaction-based assays were done to detect Extended-Spectrum  $\beta$ -Lactamases genes (ESBLs), plasmid-mediated AmpC genes, plasmid-mediated quinolone resistance (PMQR) genes and *aac(6')-Ib* genes, phylogenetic group typing and to define ExPEC-associated traits. A single nucleotide polymorphism (SNP) PCR was done to detect *E. coli* ST131.

#### **Conclusions**

In total, 179 *E.coli* Isolates were isolated from 187 chicken meat samples. Fifteen (8.4%) isolates were belong to phylogenetic group B2, at least one of the ESBLs genes and/or PMQR determinants were detected in all of these isolates. Three isolates of group B2 contained *aac(6')-Ib-cr*. Based on the molecular definition of ExPEC, all of the B2 isolates had the status of ExEPC. The most frequent virulence factors were kpsMT II and iutA. SNP- PCR results showed that eight isolates were ST131 which is the first report from Italy and poses a potential zoonotic risk.

Investigations into the ability of our poultry ExPEC to cause human infections are warranted.

## **PSEUDOMONAS AERUGINOSA GENE EXPRESSION PROFILING FOR ENVIRONMENTAL MONITORING**

F.A. Khan<sup>1</sup>, M. Goswami<sup>1</sup>, P.E. Olsson<sup>1</sup>, J. Jass<sup>1</sup>

<sup>1</sup>*School of Science and Technology, Örebro University, Örebro, Sweden*

### **Background**

A major contributor to water pollution is the discharge of domestic and industrial waste into the environment. Although developed countries treat wastewater and sludge before releasing it into the environment, many contaminants are not completely removed by the wastewater treatment plants (WWTP) and subsequently end up in environmental waters. There are concerns that these contaminants contribute to increased virulence and/or antibiotic resistance in microbes in the environment and thus pose a health risk.

### **Objectives**

To design and apply a multi-gene expression system for *Pseudomonas aeruginosa* to predict the potential impact of soluble components released from sewage sludge on bacteria.

### **Methods**

Selected genes associated with stress response, virulence and antibiotic resistance were analysed by quantitative PCR in *P. aeruginosa* subjected to tobramycin or heat shock treatments for validation, or sewage sludge leachates from 3 Swedish WWTPs (Eskilstuna, Örebro and Västerås). *P. aeruginosa* was selected because it is normally in the environment and is also an opportunistic pathogen. The molecular profiles of the sludge leachate treatments were subjected to principle component analysis.

### **Conclusions**

The sludge leachate from Eskilstuna significantly affected more *P. aeruginosa* genes, responsible for general stress response and virulence, while sludge leachate from Västerås affected fewer genes and clustered more closely to the control. Örebro sludge leachate produced a different gene expression profile from the other two WWTPs. This suggests that the presented strategy of *P. aeruginosa* toxicogenomics has potential applications in evaluating the effects of soluble contaminants on bacteria in environmental waters for considerations in risk assessment.

**Antibiotic resistance and environment**

## **CARRIAGE OF CMY-96 MEDIATED CEPHALOSPORIN RESISTANCE IN ESCHERICHIA COLI OF FOOD ORIGIN: A REPORT FROM INDIA**

S.R. JOSHI<sup>1</sup>, S. Upadhaya<sup>1</sup>

<sup>1</sup>Department of Biotechnology and Bioinformatics, North Eastern Hill University, Shillong, India

### **Background**

**Background:** Expanded spectrum cephalosporin resistance continues to be a global threat with regard to infection control management and therapeutic options. *Escherichia coli*, being versatile in host tropism, acts as a major contributor in horizontal and vertical expansion of antibiotic resistance even without external antibiotic pressure. Food remains an important growth media for both pathogenic and non-pathogenic bacteria and a source for genetic exchange between them leading to transfer of antibiotic resistance. Thus, knowledge of these resistance determinants in non-clinical host is critical in tracking down their dissemination in trans specific level.

### **Objectives**

**Objectives:** The current investigation was undertaken to assess the occurrence of class C beta lactamase mediated cephalosporin resistance and their transmission dynamics among non-clinical isolates of *E. coli* in a high altitude city of Northeastern India.

### **Methods**

**Methods:** A total of 56 *E. coli* were recovered from 61 ready to eat food samples. Phenotypic and molecular characterization of AmpC genes was performed and MIC against oxy-iminocephalosporins was also determined. Isolates positive for *bla*<sub>CIT</sub> was checked with CMY specific primers and amplicons were sequenced. Horizontal transferability was tested by conjugation and transformation. Plasmids were further characterized by PCR based replicon typing.

### **Conclusions**

**Conclusion:** A total of 17 isolates were found harbouring *bla*<sub>CMY-96</sub> type. The gene was conjugatively transferable and maintained within W inc type plasmid of approximately 23 kb in size. Carriage of this rare type resistant determinant is of clinical and epidemiological interest as non-pathogenic organism may act as vehicle for their dissemination in community and within hospital environment.

## **ANTIFUNGAL SUSCEPTIBILITY OF ASPERGILLUS FLAVUS RECOVERED FROM CLINICAL AND ENVIRONMENTAL SPECIMENS IN IRAN.**

S. Khodaveisi<sup>1</sup>, H. Badali<sup>2</sup>, S. Rezaie<sup>3</sup>, F. Aala<sup>1</sup>

<sup>1</sup>Department of Medical Mycology and Parasitology,  
Kurdistan University of Medical Sciences, Sanandaj, Iran

<sup>2</sup>Department of Medical Mycology and Parasitology,  
Mazandaran University of Medical Sciences, Sari, Iran

<sup>3</sup>Department of Medical Mycology and Parasitology,  
Tehran University of Medical Sciences, Tehran, Iran

### **Background**

*Aspergillus flavus* is the second leading cause of invasive and non-invasive aspergillosis, also common cause of fungal sinus and cutaneous infections. Since resistance to these drugs has been seen in patients, susceptibility testing can help in defining the activity spectrum of an antifungal and determining the appropriate drug for treatment.

### **Objectives**

The aim of this study was to analyse the in vitro activities of amphotericin B, itraconazole, voriconazole, posaconazole, and caspofungin against clinical isolates of *A. flavus* recovered from clinical and environmental specimens in Iran.

### **Methods**

199 isolates of *A. flavus* (171 clinical and 28 environmental) were included in the study. All isolates were identified by typical colony and microscopic characteristics, also characterized by molecular methods. MICs and MECs were determined according to recommendations stated in the Clinical and Laboratory Standards Institute (CLSI) M38-A2 document

### **Conclusions**

The range of MIC/MEC and MIC/MEC<sub>90</sub> values were as follows: amphotericin B, 0.031-8 and 1 µg/ml; voriconazole, 0.031-8 and 1 µg/ml; itraconazole, 0.031-2 and 1 µg/ml; posaconazole, 0.008-0.5 and 0.341 µg/ml; and caspofungin, 0.008-0.25 and 0.063 µg/ml, respectively. Caspofungin was the most active drug, followed by posaconazole, itraconazole, Voriconazole, and amphotericin B. Caspofungin exhibited highly potent activity (100% of strains had MEC<sub>50</sub> and MEC<sub>90</sub> values of ≥0.5 µg/ml) against *A. flavus* strains. Among the azoles, posaconazole (MICs ≥1 µg/ml) was the most potent followed by itraconazole and voriconazole. We were not able to find significant differences in antifungal susceptibilities between strains recovered from clinical and environmental specimens (P >0.01).

<sup>1</sup>Institute of Hygiene, Medical University of Graz, Graz, Austria

<sup>2</sup>Faculty of Natural Sciences, Technical University Cottbus-Senftenberg, Cottbus, Germany

<sup>3</sup>Institute of Molecular Biosciences, Karl-Franzens University of Graz, Graz, Austria

#### **Background**

Silver coated wound dressings are a new useful tool to fight bacterial infections. In vitro studies with heavy metal surfaces showed good results but only by direct contact with the patch and with a dry metal surface. But the efficacy of the coatings seems to be less effective over a longer application time.

#### **Objectives**

The aim of the study was to test heavy metal tolerance of *Staphylococcus aureus* wound isolates that had contact to silver coated wound dressing in comparison to isolates that had not.

#### **Methods**

120 *Staphylococcus aureus* patients isolates (MRSA and MSSA, with or without metal contact). Strains were analysed in a Bioscreen device over a period of 72 hours, with copper concentrations up to 20 mM copper chloride. Additionally the strains were screened for genes thought to be responsible for heavy metal tolerance (*copA*, *copB*).

#### **Conclusions**

Some isolates of both groups showed high tolerance levels for copper chloride. Surprisingly MRSA (28% positive for *copB*) came up with an overall lower metal tolerance (around 8mM) in contrast to MSSA with 9mM. Prior contact to silver dressing did not show any difference in their metal tolerance. MRSA were positive in 28% for *copB* whereas MSSA were positive in 10%. Interestingly some of the high tolerance strains showed a prolonged lag-phase over days. Therapy with silver dressings does not favor strains with higher metal tolerance. In contrast to other studies the Austrian MRSA showed lower copper tolerance than MSSA

**Antibiotic resistance and environment**

**CHARACTERIZATION OF LIPID COMPOSITION OF VANCOMYCIN-RESISTANT STAPHYLOCOCCUS EPIDERMIDIS 33 GISK**

*L. Kononova<sup>1</sup>, V. Korobov<sup>1</sup>*

*<sup>1</sup>Laboratory of microorganisms' biochemical development,  
Institute of Ecology and Genetics of Microorganisms UB RAS, Perm, Russia*

**Background**

Numerous studies have revealed that the emergence of vancomycin-resistant staphylococcal phenotype is a result of multiple mutations that markedly change biological properties of these bacteria.

**Objectives**

The goal of these investigations was the analysis of adaptation changes of *S. epidermidis* 33 GISK (Moscow) lipid composition and *S. epidermidis* 33 GISK Van<sup>r</sup> (its derivative strain) obtained via selection on media with increasing vancomycin concentrations.

**Methods**

Extraction of bacterial lipids was realized following the modified Bligh and Dyer method. Silica-gel plates Sorbfil (Russia) were used in thin-layer chromatography of lipid extracts in chloroform-methanol-water system (65:25:4, v/v). Identification of individual lipids was implemented via their functional groups' staining with specific dyes. Analysis of fatty acid methyl esters was made using RTX-5MS column (Restek) on gas chromatograph 6890N with MS-detector 5973N (Agilent Technologies). Chromatography was carried out in autonomous temperature mode (180 to 280°C) at a rate of 5°/min. Peak substances were identified with NIST98 database software library.

**Conclusions**

Increase of bacterial resistance to vancomycin is accompanied by augmentation of cardiolipin and phosphatidylglycerol content in cell membrane lipid components, and the occurrence of lysyl phosphatidylglycerol and phospholipid lysoforms therein, but decline in glycolipid content.

According to data obtained the main point of lipid composition alteration in Van<sup>r</sup> strain was the occurrence of unidentified phospholipid containing the alanine residue. Gas-chromatographic assay demonstrated that saturated and mono-unsaturated fatty acids C<sub>16</sub> and C<sub>18:1</sub> were the predominant components of Van<sup>r</sup>-lipids, whereas fatty acids C<sub>15</sub> and C<sub>17</sub> were typical for the initial strain.

<sup>4</sup>Microbiology and Immunology, St. George's University School of Medicine,  
St. Georges, Grenada

#### **Background**

*E. coli* exhibits an increasing resistance to broad spectrum antimicrobial agents as well as the subsequent generations of these drugs. Previous genetic diversity studies indicated transmission of food-borne *E.coli* strains to human patients. Therefore it is important to study the genetic diversity and antibiotic-resistance patterns both in clinical and environmental *E. coli* to predict potential of transmission of organisms and genes antibiotic resistance.

#### **Objectives**

The aim of this study was to compare the genetic diversity and the antibiotic resistance patterns of uropathogenic *E.coli* (UPEC), to strains from freshwater, seawater and iguanas.

#### **Methods**

*E.coli* isolates were identified using API20E and ATCC 25922, Rep-(GTG)<sub>5</sub> PCR and BOX-PCR extragenic DNA fingerprinting, and FigTree™. The antibiotic resistance was assessed using the Kirby-Bauer disc diffusion against the eleven most commonly prescribed antibiotics in Grenada. Excel t-test and Statistica™ were utilized for comparison of patterns of drug resistance among four

## Conclusions

Both DNA fingerprinting methods targeted non-protein coding or extragenic DNA and demonstrated enormous diversity within the population of the studied bacteria. UPEC expressed resistance patterns similar to the marine for 50%, while both to iguana and to fresh water isolates for 72.7% of drugs tested. There were only three drugs which showed significant difference between the UPEC and the freshwater isolates, namely ampicillin, amoxicillin/clavulanate and nitrofurantoin. We identified resistance to  $\beta$ -lactam antibiotics and lack of resistance to ciprofloxacin and gentamycin both in clinical strains of *E.coli*. The fractions of drug resistance strains and resistance patterns of the UPECs were similar to *E.coli* isolated from natural sources in Grenada.

**MOLECULAR EPIDEMIOLOGY OF CARBAPENEM RESISTANT  
ACINETOBACTER BAUMANNII (CRAB) IN SEPTICAEMIC & MENINGITIS  
PATIENTS IN A TERTIARY CARE HOSPITAL**

S. Kumar<sup>1</sup>, V. Gautam<sup>1</sup>, R. Agarwal<sup>2</sup>, P. Ray<sup>1</sup>

<sup>1</sup>Medical Microbiology, PGIMER, chandigarh, India

<sup>2</sup>Pulmonary Medicine, PGIMER, chandigarh, India

**Background**

Due to escalating resistance to a range of antimicrobial agents, carbapenem resistant *Acinetobacter baumannii* (CRAB) has become a worldwide concern. Rapidly increasing prevalence of CRAB in many parts of the world in the past few years has questioned the reliability of the carbapenems.

**Objectives**

This study aimed to correctly identify *A. baumannii* species, antimicrobial susceptibility, and clonal relationships of CRAB clinical isolates.

**Methods**

Clinical isolates of *A. baumannii* collected from Clinical Bacteriology Laboratory between Sept 2013 and June 2014 were used in this study. Genospecies identification was verified by MALDI-TOF, and using polymerase chain reaction for *OXA-51* & *gyrB* genes. MIC for meropenem, imipenem & doripenem was determined using agar dilution method. Antibiotic susceptibility was performed using Kirby-Bauer disc diffusion method. Multi-locus sequence typing (MLST) was performed to study clonal relationships.

**Conclusions**

Our results demonstrate clonal spread of CRAB in our hospitals. Further MLST studies on a nationwide basis would provide a better insight into the transmission and dissemination of CRAB clones.

**Antibiotic resistance and environment**

**IDENTIFICATION OF A HEAT STABLE BETA-LACTAMASE, WHICH IS PRODUCE BY BACILLUS CEREUS NBRC13494, INACTIVATES THE MEROPENEM**

R. Kuwana<sup>1</sup>, T. Yamashita<sup>2</sup>, K. Honke<sup>2</sup>, K. Ito<sup>1</sup>, H. Takamatsu<sup>1</sup>

<sup>1</sup>Pharmaceutical Sciences, Setsunan University, Hirakata, Japan

<sup>2</sup>Center for Innovative and Translational medicine, Kochi University, Kochi, Japan

**Background**

Antibiotics are used for the medical care, the domestic animals growth, and the control of health administration. Some antibiotics exposed in the environment are stable and keep the activities, which potentially causes the potential ecological and human health issue. The penem antibiotics, which are hardly to be degraded, are frequently used in Japan.

**Objectives**

In order to reduce the antibiotics pollution, we aimed to isolate soil bacteria that produce meropenem digestion enzymes.

**Methods**

Genome sequence analysis reveals that the some *Bacillus* species potentially produce antibiotic degradation enzymes. We screened *Bacillus* strains that can digest the meropenem from Biological Resource center in Japan and the soils.

**Conclusions**

We found *B. cereus* strain NBRC13494 and three natural isolates, SUBC1002, SUBC1008, and SUBC1010. The MICs of meropenem were 6.7, 2.5, 3.3, 3.4 mg/l, respectively. *B. cereus* strain NBRC13494 possessed the highest beta-lactamase activity among them. We found that the supernatant of *B. cereus* NBRC13494 after the heat treatment at 80 °C was also effective to degrade the meropenem. We resolved the proteins included in the supernatant of *B. cereus* NBRC13494 by SDS-PAGE and found major two bands with the molecular mass of 28-kDa and 33-kDa bands. We determined their amino acid sequences by LC-MS/MS. The 28-kDa protein corresponded to the *B. cereus* 5/B/6 beta-lactamase II. The 33-kDa protein corresponded to the *B. cereus* 5/B beta-lactamase I. These beta-lactamases belong to the different protein family and highly conserved among *B. cereus* group. These results suggested that some beta-lactamases produced by *B. cereus* strains potentially digested the meropenem.

### **Antibiotic resistance and environment**

#### **IDENTIFICATION AND PREVALENCE OF ANTIBIOTIC RESISTANCE GENES IN FRESHWATER URBAN WATERSHEDS**

A. Low<sup>1</sup>, C. Ng<sup>1</sup>, X.C. Liu<sup>1</sup>, S. Low<sup>1</sup>, Y.Z. Koh<sup>1</sup>, J.Z. He<sup>1</sup>

<sup>1</sup>Department of Civil and Environmental Engineering,  
National University of Singapore, Singapore, Singapore

#### **Background**

Antibiotic resistance genes (ARGs) of environmental origin have been identified as a potential source of the rise in antibiotic resistance in communities. To understand the risk of ARGs in source waters, identification and quantification of ARGs in watersheds is necessary. Here, two urban watersheds with different land-use profiles were studied: a river situated in an urbanized environment and a lake situated in a reserved environment.

#### **Objectives**

To identify and quantify ARGs using GeoChip microarray and quantitative PCR (qPCR).

#### **Methods**

To screen for ARGs, GeoChip version 5, which target 17 families of ARGs, was used to screen DNA extracted from three sampling sites at each watershed. Primers for qPCR were designed based on ARGs yielding the highest GeoChip intensities.

#### **Conclusions**

Based on GeoChip analysis, ABC transporters, multidrug and toxic efflux, multidrug resistance efflux pumps, multi-facilitator superfamily (MFS), small multidrug resistance (SMR),  $\beta$ -lactamases (A-D), tetracycline resistance (*tet*), vancomycin, virginiamycin resistance gene B (*vgb*), fosfomycin resistance (*fosA*, *fosB*, *fosX*) and quinolone resistance (*qnrC*) were detected in both watersheds. There was significantly higher intensity of  $\beta$ -lactamase A ( $p<0.05$ ), MFS ( $p<0.01$ ),  $\beta$ -lactamase C ( $p<0.01$ ), SMR ( $p<0.01$ ), and *vgb* genes ( $p<0.01$ ) in the urban environment than in the reserve; contrarily, *fosA* had a higher intensity in the reserve.

Quantification of *tet* and MFS revealed presence of these genes in low relative abundance (<2.5%) to 16S rRNA genes in both watersheds. Taken together this data

suggests that there are more ARGs in the urban than the reserve watershed and that only a sub-population of the bacterial community harbours these genes.

Kalmar, Sweden

<sup>4</sup>Department of Virology Immunobiology and Parasitology,  
Swedish Veterinary Institute, Uppsala, Sweden

**Background**

Very low concentrations of antibiotics, more than a hundred times lower than the minimal inhibitory concentration (sub MIC), can select for antibiotic resistant bacteria *in vitro*.

**Objectives**

To investigate if sub MIC concentrations of antibiotics in the environment can select for antibiotic resistant bacteria present in the intestine of mallards and to study if and how rapidly different ESBL *E.coli* strains transmit within a flock of mallards.

**Methods**

In the selection study birds were infected with an equal amount of two isogenic ESBL producing *E. coli* strains where one is resistant to ciprofloxacin. Mallards were exposed to different concentrations of ciprofloxacin in the drinking water. Faecal samples were analysed and the ratios of ciprofloxacin resistant over ciprofloxacin susceptible bacteria were calculated.

In the carriage and transmission study four different ESBL *E. coli* strains with different resistance patterns were used to inoculate a group of mallards. Faeces samples from each bird were collected up to 29 days post infection and colonies were patched onto selective plates to follow each of the inoculated strains.

**Conclusions**

Low levels of antibiotics (<20 ng/ml) in the water source of birds enrich for antibiotic resistant bacteria. Resistant bacteria can be carried in a flock of birds for at least a month without any antibiotic selective pressure and antibiotic resistant bacteria rapidly spread in the flock of birds.

**EXTRACELLULAR VESICLES AND RESISTANCE OF MYCOPLASMAS TO FLUOROQUINOLONES: RESISTOME OF *ACHOLEPLASMA LAIDLAWII***

E.S. Medvedeva<sup>1</sup>, N.B. Baranova<sup>1</sup>, T.Y.U. Grigoreva<sup>1</sup>, A.A. Mouzykantov<sup>1</sup>, E.A. Boulyguina<sup>2</sup>, M.N. Siniagina<sup>2</sup>, M.N. Davydova<sup>1</sup>, O.A. Chernova<sup>1</sup>, V.M. Chernov<sup>1</sup>

<sup>1</sup>The Laboratory of Molecular Bases of Pathogenesis,  
Kazan Institute of Biochemistry and Biophysics RAS, Kazan, Russia

<sup>2</sup>Interdisciplinary centre of proteomic researches, Kazan Federal University, Kazan, Russia

**Background**

Control of mycoplasma infections presents a serious problem which solution is connected with elucidating molecular-genetic mechanisms of mycoplasma adaptation to environments. Sequencing of bacterial genomes provides an opportunity for application of postgenomic technologies to study the above-mentioned processes. In our studies it was shown for the first time that adaptation to environments of *Acholeplasma laidlawii* – the 'ubiquitous' mycoplasma which is the major contaminant of cell cultures and the causative agent of phytomycoplasmoses, was associated with not only specific modulation of transcriptome and proteome profiles of the bacterium but secretion of extracellular vesicles.

**Objectives**

Comparative analysis of genome and proteome profiles and vesicular content of *Acholeplasma laidlawii* strains with different susceptibility to ciprofloxacin was the object of our work.

**Methods**

The TEM, SEM, LC-ESI-MS/MS and DNA sequencing were used in our study

**Conclusions**

As a result of our studies it was found that *A. laidlawii* strains with different susceptibility to ciprofloxacin differed significantly on complete nucleotide sequences of genomes, vesiculation level, cellular and vesicular proteomes. Furthermore, it was revealed that the extracellular vesicles of *A. laidlawii* mediated export of ciprofloxacin as well as mutant nucleotide sequences of the genes that encoded the antibiotic-targeted proteins. The obtained data provided a necessity for correction of current notion about the mechanisms that facilitate the rapid development of resistance to antibacterial agents in mycoplasmas and approaches to control of mycoplasma infections.

### Antibiotic resistance and environment

#### DOES THE HOST MAKE A DIFFERENCE IN THE SPREAD OF ANTIBIOTIC RESISTANCE GENES IN WATER?

C. Narciso-da-Rocha<sup>1</sup>, C.M. Manaia<sup>1</sup>

<sup>1</sup>CBQF – Centro de Biotecnologia e Química Fina,  
Escola Superior de Biotecnologia – Universidade Católica Portuguesa, Porto,  
Portugal

#### Background

Hospital and municipal effluents receive high doses of antibiotic resistant bacteria and their genes (ARB&ARG), some of which can persist in the environment. Little is known about the factors influencing the fate of ARG when they are introduced in complex microbial communities.

#### Objectives

This study aimed at assessing the fate of some indicator genes hosted by different bacterial species when inoculated in wastewater.

#### Methods

Assays were performed in microcosms of hospital effluent, raw wastewater, treated wastewater and sterile ultrapure water. Replicas of these microcosms were inoculated with *Acinetobacter johnsonii* (*intl1*), *Escherichia coli* (*bla*<sub>TEM</sub>, *intl1*) and *Enterococcus faecium* (*vanA*) or with *Acinetobacter johnsonii* (*intl1*), *Klebsiella pneumoniae* (*bla*<sub>TEM</sub>, *intl1*) and *Enterococcus faecalis* (*vanA*). Inoculated and non-inoculated microcosms incubated for 15 days at 18 or 30°C, the genes were quantified by qPCR and bacterial community composition was assessed based on 16S rRNA gene-denaturing gradient gel electrophoresis.

#### Conclusions

In general, the bacterial community richness, diversity and evenness indices did not vary over the incubation period and similar results were observed at 18°C or 30 °C. Both *vanA* and *bla*<sub>TEM</sub> were observed to decay over time, with higher reduction than the genes 16S rRNA and *intl1*. The gene *vanA* decreased sharply after the incubation period irrespective of the gene host or type of water used in the microcosm. In contrast, the decay of the gene *bla*<sub>TEM</sub> varied with the host and type of water. Comparatively, *K.pneumoniae* presented a higher fitness in water than *E.coli*, suggesting the importance of the host in the spread of some ARG.

#### **DIVERSITY AND ANTIBIOTIC RESISTANCE PATTERNS OF BACTERIAL ISOLATES FROM TWO RIVERS IN NORTHERN PORTUGAL**

C. Narciso-da-Rocha<sup>1</sup>, I. Vaz-Moreira<sup>1</sup>, M. Valente<sup>2</sup>, C. Manaia<sup>1</sup>

<sup>1</sup>CBQF – Centro de Biotecnologia e Química Fina,  
Escola Superior de Biotecnologia – Universidade Católica Portuguesa, Porto,  
Portugal

<sup>2</sup>Águas do Douro e Paiva, S.A., Porto, Portugal

#### **Background**

Aquatic environments are important habitats for bacteria and water is a privileged mode of dissemination of microorganisms. Freshwater is inhabited by different bacterial populations, mostly strictly environmental, in pristine environments, and also of human/animal origin, in human-impacted areas. The rivers that flow in urban areas are often inhabited by both environmental and animal/human derived microorganisms.

#### **Objectives**

The study of the diversity and antibiotic resistance patterns of bacteria colonizing freshwater habitats brings interesting insights into the role of the natural and human-derived microbiota in the evolution of antibiotic resistance. This study explored the taxonomic diversity and antibiotic resistance patterns of bacteria isolated from freshwater.

#### **Methods**

Water and/or sediment samples were collected from rivers Ferreira (43 km) and Douro (897 km), in Northern Portugal. Heterotrophic bacteria were enumerated and isolated on plate count agar (PCA) or on PCA supplemented with antibiotics (PCA+A). The isolates (n=173) were characterized for their antibiotic resistance phenotypes and multidrug resistant (MDR) bacteria (to antibiotics of  $\geq 4$  classes) were identified based on 16S rRNA gene sequence analysis.

#### **Conclusions**

In both rivers, PCA counts ranged  $10^5$  CFU/g of the sediments being about 1-3 log less on PCA+A (ciprofloxacin, meropenem, gentamycin). In both Ferreira and Douro, the most prevalent antibiotic resistance phenotypes were for beta-lactams and sulfonamides and the least prevalent was for tetracycline. Ceftazidime, meropenem and ciprofloxacin resistance was more prevalent in Douro than in Ferreira isolates. About 40% of the isolates from PCA+A were MDR and the most common genera were *Pseudomonas*, *Chryseobacterium* and *Stenotrophomonas*, in Ferreira and *Chitinophaga* in Douro.

**FEMS-1769**

**Antibiotic resistance and environment**

**INDUCTION OF THE SOS RESPONSE BY ANTIBIOTICS THAT DO NOT TARGET DNA IN *V. CHOLERA***

V. Negro<sup>1</sup>, Z. Baharoglu<sup>1</sup>, D. Mazel<sup>1</sup>

<sup>1</sup>*Genomes and Genetics, Institut Pasteur, Paris, France*

**Background**

The bacterial SOS response is a global stress response involved in DNA-damage repair. In *Escherichia coli* it is induced after DNA damage, for example after treatment with antibiotics that target DNA. The SOS response is also involved in genome plasticity and in the acquisition of resistance to antibiotics. Unexpectedly, the SOS response is induced in *Vibrio cholera* by exposure to sub-inhibitory concentrations (sub-MIC) of different families of antibiotics that do not target DNA, such as aminoglycosides, chloramphenicol and tetracycline. The use of a genetic screen led to the isolation of mutants in which induction of the SOS response by sub-MICs of aminoglycosides is lost. One of these mutants is inactivated for the *vc1636* gene, which encodes a putative DNA/RNA helicase.

**Objectives**

The purpose of this project is to characterize the protein encoded by the *V. cholerae* *vc1636* gene and to understand the induction of the SOS response by antibiotics that do not target DNA in *V. cholerae*.

**Methods**

Towards this goal we use several bacterial genetics assays.

**Conclusions**

The first results suggest that VC1636 plays an important role in DNA-damage repair.

**FEMS-2566**

**Antibiotic resistance and environment**

**ANTIMICROBIAL AND VIRULENCE FACTORS OF *V. PARAHAEMOLYTICUS* ISOLATED FROM THE FINAL EFFLUENTS OF WASTEWATER TREATMENT PLANTS**

*V. Nongogo*<sup>1</sup>, *A.I. Okoh*<sup>1</sup>

<sup>1</sup>*Biochemistry and Microbiology, University of Fort Hare, Alice, South Africa*

**Background**

Enteric pathogens, including *Vibrio* species, increasingly survive wastewater treatment processes, thus constituting threat to humans as final effluents are discharged into receiving water bodies used primarily as source of domestic or recreational waters. *V. cholerae* has been reported from various water sources however, other pathogenic species have been under reported in wastewater hence the focus is on *V. parahaemolyticus* for this study.

**Objectives**

The objectives of the study were to: Isolate and confirm presumptive *Vibrio* species while determining their incidence; Confirm *V. parahaemolyticus* using PCR; Determine the antibiogram characteristics of *V. parahaemolyticus* and determine the virulence factors specifically the *tlh* and *trh* gene of *V. parahaemolyticus*.

**Methods**

Wastewater final effluents were collected once, monthly, for a period of twelve months, membrane filtered and analysed in accordance with standard technique. Presumptive *Vibrio* isolates were confirmed via 16SrRNA gene and *V. parahaemolyticus* identified with *toxR* gene. Antimicrobial susceptibility test was done using 10 different antibiotics and virulence factors namely the thermostable direct haemolysin related haemolysins (*trh* gene) and thermolabile haemolysin (*tlh* gene) were assessed using PCR

**Conclusions**

Incidence of *Vibrio* species varied with months and treatment plants. Resistance was shown against certain antibiotics while in other antibiotics resistance varied. The incidence of *trh* genes was nil, while the *tlh* gene was 5.7 %. Although, the incidence of virulence determinants in *V. parahaemolyticus* were few, their presence portends a public health risk to the receiving water bodies used by humans and animals especially with the increasing resistance of the pathogens to antibiotics.

**FEMS-0514**

**PHENOTYPIC AND MOLECULAR CHARACTERIZATION OF KLEBSIELLA SP FROM URINE SAMPLES OF IN- AND OUT-PATIENTS IN SOME HEALTH INSTITUTIONS IN NIGERIA**

A. Oluduro<sup>1</sup>, Y. Simaren<sup>1</sup>

<sup>1</sup>Microbiology, Obafemi Awolowo University, Ile-Ife, Nigeria

**Background**

*Klebsiella* species are important pathogens in nosocomial infections, most especially the multiple antibiotic resistant strains.

**Objectives**

The aim of this study was to isolate and identify *Klebsiella* sp from urine samples of in- and out-patients in some health institutions in Ile-Ife, Nigeria; determine the resistance pattern; detect plasmid DNA, resistance and virulence genes in multiple antibiotic resistant *Klebsiella* isolates.

**Methods**

Isolation of *klebsiella* sp was carried out on MacConkey agar plate at 37°C. Identification was done using standard techniques. Antibiotic sensitivity was determined using Kirby-Bauer's disc diffusion method. Plasmid DNA was extracted by alkaline lysis, resistance (*bla*CTX, *tet*M) and virulence (*cps* and *fim*H) genes were detected by PCR.

**Conclusions**

A total of 32 (7.02%) *Klebsiella* sp were identified, out of which 29 (90.63%) were multiple antibiotic resistant (MAR). Resistance to antibiotics varied greatly. The isolates showed high resistance to augmentin (93.75%) and tetracycline (71.88%). There was diversity in the MAR pattern with 21 different antibiotypes which ranged from two to ten antibiotics. Thirteen out of the 18 randomly selected MAR isolates harboured plasmids ranging from 900bp to 9416bp. Three (16.67%) of the isolates had *bla*CTX (543 bp) and *cps* (418 bp) genes while one (5.56%) harboured *fim*H (1250 bp) gene. However, *tet*M (974 bp) gene was not detected in any of the isolates. The incidence of MAR *Klebsiella* sp in the study is high and calls for great concern in health care delivery with great economic and health consequences.

### **Antibiotic resistance and environment**

#### **AEROMONAS SPP. – B-LACTAMASES RESISTANCE IN WASTEWATER TREATMENT PLANT STRAINS**

M. Piotrowska<sup>1</sup>, M. Popowska<sup>1</sup>

<sup>1</sup>*Department of Applied Microbiology, University of Warsaw Faculty of Biology, Warsaw, Poland*

#### **Background**

Bacteria of the *Aeromonas* genus are fish and human pathogens commonly occurring in various aquatic ecosystems (Janda and Abbott, 2010). Literature data show a wide spread of drug resistance genes among these microorganisms with a high proportion of chromosomal and plasmid-mediated genes (Piotrowska and Popowska, 2014).

#### **Objectives**

The aim of this project was determination of antibiotic resistance genes in the  $\beta$ -lactam unsusceptible *Aeromonas* strains isolated from wastewater with different levels of purification. In addition, in drug-resistant strains, their plasmid profile and the conjugation potential was defined.

#### **Methods**

The double-disk synergy test was performed to determine the mechanisms of  $\beta$ -lactamases resistance (AmpC, ESBL, carbapenemases). In addition, disk-diffusion were performed to determine the bacterial antibiogram. Identification of resistance genes was performed by PCR (Multiplex) and confirmed by sequencing. Plasmids were isolated by alkaline lysis and commercial kits. Diversity of plasmids were evaluated by plasmid restriction profiles by comparison of their patterns obtained after digestion with different restriction enzymes. The conjugative transfer ability and host range of selected plasmids were performed according to standard methods.

#### **Conclusions**

*Aeromonas* strains existing in wastewater are  $\beta$ -lactam resistant and possess a variety of  $\beta$ -lactamases. We found and confirmed the genes encoding  $\beta$ -lactamase from variety of families e.g. OXA, TEM, SHV, GES, VEB, FOX and characteristic to *Aeromonas* spp. chromosomal metallo- $\beta$ -lactamase CphA. Some of the resistant strains possess plasmids which were characterized by a different profiles.

**Antibiotic resistance and environment**

**IMPACT OF URBAN CONTAMINATION OF LA PAZ RIVER ON THE ABUNDANCE OF FECAL COLIFORMS, AND ANTIBIOTIC RESISTANT GRAM-NEGATIVE BACTERIA IN RIVER WATER, SOIL AND VEGETABLES**

*V. Poma<sup>1</sup>, V. Iñiguez<sup>1</sup>*

*<sup>1</sup>Environmental Microbiology, Instituto de Biología Molecular, La Paz, Bolivia*

**Background**

Worldwide, contamination of fresh water resources affects food security and ecosystem sustainability. This situation is aggravated in developing countries and markedly in dry regions such as the Bolivian Highlands. In this region along with a shortage of water, urban wastewater is directly discharged into fresh water bodies contributing to aquatic ecosystem degradation, as observed in La Paz River, which receives urban discharges that further contaminate agricultural lowlands, where vegetables and soil are directly irrigated by river water

**Objectives**

To evaluate the microbial quality of river surface water at unimpacted and impacted sites, and tested for antibiotic resistance of gram-negative bacteria isolated from river water, soil and vegetable samples.

**Methods**

Culture dependent methods.

**Conclusions**

High levels of fecal coliform density were found along impacted sites and green-leafy vegetable samples, exceeding at least in two and one order of magnitude respectively, the allowable concentration. Antibiotic resistance among gram-negative bacterial isolates was common at all sites. A spatial distribution of antibiotic resistance was found, where resistance frequency to not commonly used antibiotics was higher at unimpacted in contrast to impacted sites and vice versa, this distribution was associated with the density of fecal coliforms. Multiple Antibiotic Resistance (MAR) index values ranged from 0.176 to 0.310, being higher in soil samples. Overall, this study suggest that surface water, soil and vegetables can be reservoirs of antibiotic resistant gram-negative bacteria, highlighting health risk associated with vegetables production and consumption in the region.

**QUINOLONE RESISTANCE IN LACTOBACILLUS  
CASEI/PARACASEI/RHAMNOSUS**

F. Rossi<sup>1</sup>, R. COPPOLA<sup>1</sup>, A.N.N.A. Reale<sup>2</sup>

<sup>1</sup>Università degli Studi del Molise, Dip AAA, Campobasso, Italy

<sup>2</sup>ISA-CNR, Istituto di Scienze dell'Alimentazione - CNR, Avellino, Italy

**Background**

Resistance to quinolones has been little studied in lactobacilli and the breakpoint value established to discriminate resistant from sensitive strains, the same for all *Lactobacillus* species, has not been updated since 2003 (1).

High level of resistance is, in most cases, due to mutations in the quinolone resistance determining regions (QRDR) of the genes encoding DNA gyrase (*gyrA*) or topoisomerase IV (*parC*). Reduced sensitivity to quinolones is conferred by genes, among which the most widespread are the *qnr* genes for pentapeptide repeat family proteins that protect gyrase from quinolone inhibition, encoded by plasmids or integrons in Gram-negative bacteria and chromosomally in some Gram-positive bacteria (2).

**Objectives**

This study was aimed at understanding if the species of probiotic interest *Lactobacillus casei/paracasei/rhamnosus* may have a role in the spread of quinolone resistance.

**Methods**

Strains resistant to ciprofloxacin were selected among 184 *L. casei/paracasei/rhamnosus* bacteria by using the breakpoint concentration for lactobacilli (4 mg/l) in LSM medium. These were tested for the presence of mutations in the *gyrA* and *parC* QRDRs and of genes conferring quinolone resistance.

**Conclusions**

Among the 31 strains resistant to the breakpoint value for ciprofloxacin only one *L. rhamnosus* strain presented a mutation in the *gyrA* QRDR, not corresponding to those commonly associated to resistance. Results showed that quinolone resistance is intrinsic in some strains of *L. casei/paracasei/rhamnosus*.

#### SCREENING BACTERIA ISOLATED FROM AQUATIC ENVIRONMENTS FOR THE POTENTIAL TO DEGRADE SULFAMETOXAZOLE

P.J.M. Reis<sup>1</sup>, V.J.P. Vilar<sup>2</sup>, C.M. Manaia<sup>3</sup>, O.C. Nunes<sup>1</sup>

<sup>1</sup>LEPABE – Laboratory of Process Engineering Environment Biotechnology and Energy, Faculdade de Engenharia - Universidade do Porto, Porto, Portugal

<sup>2</sup>LSRE – Laboratory of Separation and Reaction Engineering – Associate Laboratory LSRE/LCM, Faculdade de Engenharia - Universidade do Porto, Porto, Portugal

<sup>3</sup>CBQF – Centro de Biotecnologia e Química Fina – Laboratório Associado, Escola Superior de Biotecnologia Universidade Católica Portuguesa, Porto, Portugal

#### Background

In contrast to beta-lactam antibiotics, the biodegradation of sulfonamides seems to be uncommon in nature, in spite of the extensive use and environmental contamination associated with these drugs.

#### Objectives

The aim of this study was to investigate the potential of sulfonamide resistant bacteria isolated from wastewater, surface water, bottled mineral water, and different sites within a drinking water treatment plant, including distribution system and tap water, to degrade sulfamethoxazole (SMX).

#### Methods

From a total of 133 isolates, were selected 51 representative strains affiliated to 19 genera - *Pseudomonas*, *Sphingomonas*, *Blastomonas*, *Acinetobacter*, *Aeromonas*, *Variovorax*, *Microbacterium*, *Duganella*, *Bosea*, *Afipia*, *Brevundimonas*, *Acidovorax*, *Rhizobium*, *Klebsiella*, *Citrobacter*, *Raoultella*, *Enterobacter*, *Kluyvera*, and *Stenotrophomonas* to test the ability to degrade SMX. The biodegradation experiments were carried out in mineral and complex culture media supplemented with 50 mg/L SMX.

#### Conclusions

Five isolates belonging to the genus *Pseudomonas* and one to the genus *Stenotrophomonas* were able to degrade SMX in complex culture medium. *Pseudomonas mandelii* isolated from bottled mineral water and *Stenotrophomonas maltophilia* isolated from river water were the most efficient SMX-degrading bacteria, removing 67% and 38% of the initial SMX content after 15 days of incubation, respectively.

Based on the potential application of these microorganisms or catalysts thereof, further research on the SMX degradation kinetics and metabolites are under study and will be discussed with what is described for other *Proteobacteria* and *Actinobacteria*.

#### **EXTENDED-SPECTRUM BETA-LACTAMASE (ESBL) PRODUCING ESCHERICHIA COLI AND KLEBSIELLA PNEUMONIAE STRAINS IN THE HUMAN MICROBIOTA BIOBANK (HUMB) AT THE DEPARTMENT OF MICROBIOLOGY, UNIVERSITY OF TARTU**

T. Rööp<sup>1</sup>, A. Pavelkovich<sup>2</sup>, J. Lillo<sup>1</sup>, M. Ivanova<sup>3</sup>, K. Pai<sup>1</sup>, K. Parv<sup>1</sup>, K. Pärna<sup>1</sup>, E. Sepp<sup>1</sup>, P. Naaber<sup>1</sup>, R. Mändar<sup>1</sup>, S. Kõljalg<sup>1</sup>

<sup>1</sup>Department of Microbiology, University of Tartu, Tartu, Estonia

<sup>2</sup>Faculty of Science, Tallinn University of Technology, Tallinn, Estonia

<sup>3</sup>Central Laboratory, East-Tallinn Central Hospital, Tallinn, Estonia

#### **Background**

Extended-spectrum beta-lactamase (ESBL)-producing *Enterobacteriaceae* is an increasing public health problem. Extensive collection of these strains is needed to analyse the issue more thoroughly. Human Microbiota Biobank (HUMB) at University of Tartu ([www.eemb.ut.ee/eng/](http://www.eemb.ut.ee/eng/), WFCC-MIRCEN no. 977) is a scientific collection that contains beneficial and opportunistic microbial strains of human origin.

#### **Objectives**

To form the subcollection of ESBL positive *Enterobacteriaceae* strains in HUMB for further pheno- and genotypic characterisation.

#### **Methods**

More than 1200 strains of ESBL positive *Escherichia coli* and *Klebsiella pneumoniae* were collected from 20 hospitals in Estonia (n=627), Latvia (n=182), Lithuania (n=134) and St. Petersburg region in Russia (n=322) in 2011-2012. The strains were identified by MALDI-TOF MS and deposited at the HUMB collection (stored at -80°C in multiple parallels in multiple freezers). Bacterial isolates were compared according to clinical material, geographical origin, phylogenetic group, antibiotic susceptibility and virulence factor genes.

First results of the subcollection of ESBL producing strains have been published (Pavelkovich 2014; Lillo 2014). The regional differences of virulence factor genes and carbapenemase resistance remained statistically significant after taking into account the phylogenetic distribution in the countries. MALDI-TOF MS-based assay appeared to be suitable, quick and cost-effective method for the initial confirmation of carbapenemase production.

#### **Conclusions**

Subcollection of ESBL producing strains stored in HUMB have significant scientific value that has to be further studied for epidemiological purposes and for creating evidence-based suggestions for clinicians.

### **Antibiotic resistance and environment**

#### **IMPACT OF AOP ON ANTIBIOTIC RESISTANT BACTERIA AS PART OF THE WASTEWATER EFFLUENT MICROBIOM**

T. Schwartz<sup>1</sup>, J. Alexander<sup>1</sup>, G. Knopp<sup>2</sup>

<sup>1</sup>*Institute of Functional Interfaces (IFG), Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany*

<sup>2</sup>*IWAR Wastewater Technology, Technical University of Darmstadt, Darmstadt, Germany*

Wastewater treatment plants are one source of microbial contamination. In the light of recent studies there are reports of increased levels of multi-resistant bacteria and antibiotic resistance genes (ARGs) in wastewater treatment plants (WWTPs) and downstream habitats. Conventional WWTPs represent a reservoir for the dissemination of ARGs in the bacterial communities. Horizontal gene transfer (HGT) of antibiotic resistance genes contributes to increased abundances of hygienically relevant, antibiotic resistant bacteria in aquatic systems. Advanced oxidation processes (AOPs) as additional wastewater treatment techniques are investigated to decrease the bacterial load and the dissemination of antibiotic resistances in adjacent downstream aquatic habitats.

To investigate the efficiency of ozonation to reduce the bacterial load, the project includes detection and quantification of facultative pathogens and medically relevant antibiotic resistance genes in microbial communities by qPCR analysis.

We investigate the impact of ozonation by molecular quantification of the methicillin resistance gene *mecA* from staphylococci, the ampicillin resistance gene *ampC* from Enterobacteriaceae, the transposon mediated vancomycin resistance gene *vanA* from enterococci, the imipenem resistance gene *blaVIM* from *Pseudomonas aeruginosa*, and the erythromycin resistance gene *ermB* from streptococci.

As expected, most of the hygienically relevant bacteria were reduced during ozonation, but it became obvious that bacteria carrying antibiotic resistance genes showed a considerable robustness and fitness against ozonation. This indicates a selection-like process favoring already antibiotic resistant bacteria during oxidative wastewater treatment. Further investigations regarding drug-dependent predispositions and different bacterial stress response mechanisms are currently analyzed to characterize the bacterial adaptation.

**Antibiotic resistance and environment**

**RESISTANCE TO AZTREONAM IN ENVIRONMENTAL ISOLATES OF PSEUDOMONAS AERUGINOSA RESULTS FROM HYPEREXPRESSION OF MEXAB-OPRM INDUCED BY MUTATION IN NALC GENE.**

V.S. Braz<sup>1</sup>, J.P.R. Furlan<sup>1</sup>, A.F.T. Fernandes<sup>1</sup>, E. Stehling<sup>1</sup>

<sup>1</sup>DACTB, Faculdade de Ciencias Farmaceuticas de Ribeirao Preto, Ribeirão Preto, Brazil

**Background**

Bacteria belonging to the genus *Pseudomonas* have a great metabolic versatility and acquire resistance to a wide variety of antimicrobials. Resistance to the monobactam aztreonam occurs primarily by changing in the efflux pump MexAB-OprM system. Three transcriptional regulators modulate the expression of this operon: MexR, from MarR family, and NalD and NalC, TetR family members. NalC is an anti-repressor that allosterically inhibits the MexR dimer formation and, then, MexR is released from the mexAB-oprM promoter, leading to an upregulation of this operon.

**Objectives**

This study aimed to determine the resistance profile to aztreonam in 50 *P. aeruginosa* isolates and to determine if mutations in the regulatory genes affected the expression of MexAB-OprM efflux pump.

**Methods**

The soil sample was collected and processed according to the method describe by Mukherjee et al. (2010), and the resistance profile was determined by the Minimum Inhibitory Concentration (MIC) method. The transcriptional regulators *mexR*, *nalC* and *nalD* were amplified by PCR, and the expression of MexAB-OprM was measured by quantitative real-time reverse transcriptase-PCR (qRT-PCR).

**Conclusions**

All isolates analyzed had some amino acid substitution in NalC, only one isolate showed a substitution at MexR and no single mutation was detected into NalD protein. Just the isolate that presented mutation at position 186 had MIC more than 250 µg mL<sup>-1</sup> and showed a greater increase in the level of *mexA* expression, about 92.6 fold more than that found in the wild-type PAO1 strain.

#### **GENETIC DIVERSITY AND ANTIMICROBIAL RESISTANCE OF PSEUDOMONAS AERUGINOSA ISOLATED FROM HUMAN, VETERINARY AND ENVIRONMENTAL SAMPLES IN ESTONIA**

K. Telling<sup>1</sup>, M. Laht<sup>2</sup>, V. Kisand<sup>2</sup>, T. Margus<sup>2</sup>, S. Kõljalg<sup>1</sup>, P. Kalmus<sup>3</sup>, M. Maimets<sup>4</sup>, I. Lutsar<sup>1</sup>, T. Tenson<sup>2</sup>

<sup>1</sup>Department of microbiology, University of Tartu, Tartu, Estonia

<sup>2</sup>Institute of Technology, University of Tartu, Tartu, Estonia

<sup>3</sup>Institute of Veterinary Medicine and Animal Sciences,  
Estonian University of Life Sciences, Tartu, Estonia

<sup>4</sup>Department of Internal Medicine, University of Tartu, Tartu, Estonia

#### **Background**

*P. aeruginosa* is an opportunistic microorganism widely spread in different terrestrial and aquatic environments, but it is also known multiresistant pathogen in hospital setting.

#### **Objectives**

We aimed to characterize the population structure of *P. aeruginosa* isolated from human, animal and environmental samples; to identify the potential transfer routes between various environments and to look for the associations between antibiotic resistance and potential resistance genes.

#### **Methods**

Ninety strains were collected between 2004 and 2014: 41 clinical isolates from patients with infection; 4 colonising strains from nasal and faecal samples of 287 healthy volunteers; 29 isolates from sick animals and 16 from environmental samples.

Study has been approved by Research Ethics Committee of the University of Tartu.

All samples underwent whole genome sequencing. Draft genomes were assembled followed by *in silico* identification of markers for multilocus sequence typing (MLST)

analysis. Genetic relatedness was presented as minimum spanning tree.

**Minimum spanning tree of *P.aeruginosa* from various sources.**  
Each circle corresponds to a unique sequence type from MLST database ([pubmlst.org/paeruginosa](http://pubmlst.org/paeruginosa)).  
Circle size is proportional to sequence type frequency

Coding regions for beta-lactamases were predicted from draft genomes using custom HMM profiles for Ambler class A, D, C and B beta-lactamases.

MICs to 10 antipseudomonal agents (ceftazidime, cefepime, meropenem, imipenem, piperacillin/tazobactam, amikacin, gentamycin, tobramycin, ciprofloxacin, colistin) were detected using epsilon meter test. EUCAST breakpoints and multiresistance definition were used for interpretation.

Phenotypic resistance was compared to the betalactamase genes predicted from the genomic sequences.

## **Conclusions**

Our data indicates that *P. aeruginosa* strains are transferred between different hosts and environments. The high variety of phenotypic resistance and resistance genes in bacteria of the same sequence type suggests rapid horizontal transfer of resistance.

### **Antibiotic resistance and environment**

#### **AMINOGLYCOSIDES AND PENICILLINS: ASSESSMENT OF “IN VITRO” SYNERGY FOR ENTEROCOCCUS SP – DISPARITY BETWEEN CLINICAL PRACTICE AND “IN VITRO” RESULTS**

A. Mourad<sup>1</sup>, S. Bricola<sup>2</sup>, S. Sasagawa<sup>3</sup>, S. UEDA<sup>3</sup>, L. Mimica<sup>3</sup>

<sup>1</sup>Center for Health Sciences and Pharmacy, Mackenzie University, São Paulo, Brazil

<sup>2</sup>USP hospital, São Paulo University, São Paulo, Brazil

<sup>3</sup>Pathological science, FCMSCSP, São Paulo, Brazil

#### **Background**

Developing dosage guidelines for antibiotics with mitigation of adverse risks is a goal of the rational use of medications. The use of checkerboard tests enables evaluation “in vitro” of the association of antibiotics in different concentrations and optimization of gentamicin and ampicillin concentrations in terms of therapeutic effectiveness, contributing to more effective therapeutic treatment guidelines.

#### **Objectives**

The objective of the study is to evaluate the synergism of action of gentamicin associated to ampicillin through “in vitro” studies in enterococci strains.

#### **Methods**

A total of 50 *Enterococcus sp* strains were used and the susceptibility profile to ampicillin and gentamicin evaluated separately and in combination. For each enterococci strain, a total of 36 tests were performed in 1 mL tubes with different concentrations of ampicillin and gentamicin. Figure 1.

#### **Conclusions**

A total of 1,800 tests were conducted with different concentrations of antibiotics. After 24 hours and 48 hours of incubation, the turbidity, representing the action of antimicrobial on the enterococci strains, was observed.

The synergism of action was observed in 10% of samples, with 54% indifference and 32% revealing therapeutic treatment failure. In other words, mere association of the antibiotics does not result in successful therapeutic treatment. Evaluation “in vitro” of different concentrations of antibiotics can help guide proper treatment of infections through appropriate doses that permit synergy of action and therapeutic success.

Figure 1: Checkerboard – Evaluation of the synergism of action between different concentrations of ampicillin and gentamicin on enterococci strains,  $1.5 \times 10^8$  UFC/mL.

The initial dose of antibiotics was 0.4mg/mL, corresponding to 10µg discs with progressive dilution of the antibiotics.

	Ampicillin (mg/mL)						
Gentamicin (mg/mL)		0.4	0.2	0.1	0.05	0.025	0.0
	0.4	Negative Control					
	0.2						
	0.1						
	0.05						
	0.025						
	0.0						Positive Control

#### **CORRELATING METAL CONTENT IN (EXTREMELY) POLLUTED SOIL WITH BACTERIAL RESISTANCE TO ANTIBIOTICS AND METALS**

G. van Keulen<sup>1</sup>, A. Abdelhameed<sup>1</sup>, B. Rawlins<sup>2</sup>, R. Del Sol<sup>1</sup>

<sup>1</sup>*Institute of Life Science - College of Medicine, Swansea University, Swansea, United Kingdom*

<sup>2</sup>*Sustainable Soils, British Geological Survey, Keyworth, United Kingdom*

#### **Background**

Microbes require some (trace) metals for growth, while high metal concentrations can be toxic. Metal-resistant microbes have evolved in metal-polluted environments, some of which may also have (co-)developed antibiotics resistance.

#### **Objectives**

This study aims to determine the environmental risk of (spread of) antibiotic resistance to humans from historically metal-contaminated urban areas.

#### **Methods**

This study analysed the spatial variation of the concentrations of 16 metals in 375 topsoil samples from the Swansea/Neath/Port Talbot urban area, which contain some of the highest metal-polluted soils of the UK. Pairwise correlations showed mostly significant positive associations between 16 of the studied elements, e.g. copper and arsenic. Factor analysis showed that 68% of the observed variation in concentrations could be explained by four principal components. The archived soils were then subsampled over a range of metal concentrations, yielding 65 subsamples for further biomolecular analysis.

#### **Conclusions**

Culture-dependent studies on dilute nutrient rich and humic acid agar media yielded many isolates with medium to high tolerance to several metals and antibiotics. Culture-independent studies are performed to determine the bacterial diversity and abundance of resistance genes over the wide range of observed (mixed) metal concentrations.

#### **THE HUMAN GUT AS A RESERVOIR FOR ANTIBIOTIC RESISTANCE GENES**

*E. Buelow<sup>1</sup>, T. Bello Gonzalez<sup>2</sup>, J. Bayjanov<sup>1</sup>, W.A.A. de Steenhuijsen Pijters<sup>1</sup>, D. Versluis<sup>2</sup>, M.W.J. van Passel<sup>2</sup>, H. Schmitt<sup>3</sup>, H. Smidt<sup>2</sup>, R.J.L. Willems<sup>1</sup>, M.J.M. Bonten<sup>1</sup>, W. van Schaik<sup>1</sup>*

<sup>1</sup>*Department of Medical Microbiology, University Medical Center Utrecht, Utrecht, Netherlands*

<sup>2</sup>*Laboratory of Microbiology, Wageningen University, Wageningen, Netherlands*

<sup>3</sup>*Institute for Risk Assessment Sciences, Utrecht University, Utrecht, Netherlands*

#### **Background**

The human gut harbors a densely populated microbial ecosystem, termed the gut microbiota. The gut microbiota can serve as a reservoir for antibiotic resistance genes ('the resistome') and drug-resistant opportunistic pathogens.

#### **Objectives**

In this study, we determined the dynamics of the microbiota and the resistome in thirteen patients that were hospitalized in Intensive Care Units. Because gut-associated bacteria and their resistance genes may be shed into the environment through sewage, we also assayed the levels of antibiotic resistance genes in hospital sewage and in subsequent stages of wastewater treatment.

#### **Methods**

16S rRNA profiling, functional metagenomics, metagenomic sequencing and nanolitre-scale quantitative PCRs were used in this study.

#### **Conclusions**

The gut microbiota of hospitalized patients contained genes that are predicted to confer resistance to fourteen classes of antimicrobials. Levels of antibiotic resistance genes increased during ICU hospitalization and were associated with changing patterns of the composition of the microbiota. Sequencing of vector inserts in drug-resistant fosmid clones indicated that resistance genes were mainly carried by anaerobic gut commensals (*Clostridium* and *Bacteroides*). Resistance genes were associated with mobile genetic elements, which could facilitate horizontal gene transfer of resistance genes from commensal bacteria to opportunistic pathogens. Antibiotic resistance genes were abundant in hospital sewage but the influence of hospital sewage on the abundance of resistance genes in the wastewater treatment

plant was limited. Levels of resistance genes and human-associated bacteria further decreased during wastewater treatment, limiting the dispersal of antibiotic resistance genes from hospitals into the environment.

<sup>3</sup>LEPABE - Laboratory for Process Engineering Environment Biotechnology and Energy, Faculty of Engineering University of Porto, Porto, Portugal

<sup>4</sup>ICBAS - Instituto de Ciências Biomédicas de Abel Salazar, Universidade do Porto, Porto, Portugal

#### Background

Molecular epidemiology-based studies using methods such as multilocus sequence typing (MLST) are useful to evaluate the dissemination of antibiotic resistant bacteria and their genes (ARB&ARG) in the environment. If the ARB bacteria tracked are typical human commensals like *Escherichia coli*, it is also possible to infer about the humans-environment relationship.

#### Objectives

This study aimed at assessing the genetic relatedness of quinolone unsusceptible *E. coli* isolated from different types of water, gulls, birds of prey and hospitalized patients, in order to infer about possible modes of transmission of ARB in the environment.

#### Methods

A group of 143 quinolone unsusceptible *E.coli* from clinical, wild birds and water isolates was compared based on MLST and resistance phenotype. Water isolates were further analyzed regarding the presence of chromosomal mutations in the genes *gyrA* and *parC*; of plasmid-mediated quinolone resistance (PMQR, *qnrA*, *B*, *C*, *D*, *S*, *VC*; *qepA*; *oqxAB*; *aac(6')-ib-cr*)- and beta-lactam resistance (*bla*<sub>OXA-A,B,TEM,CTX,SHV,CMY</sub>)-encoding genes; and of Inc group plasmid replicons. Water isolates carrying PMQR-encoding genes were tested for their ability to transfer resistance by conjugation.

#### Conclusions

Isolates from different sources clustered together, suggesting the ability to persist and spread across different environments. The most common sequence types were ST131 (n=26) and ST10 (n=9). 77% of the isolates were resistant to three or more classes of antibiotics. Eight water isolates harbored PMQR-encoding genes, combined with *bla*<sub>TEM</sub> (n=6) and *bla*<sub>CTX-M-15</sub> (n=2), from which seven could transfer

resistance through conjugation. These results confirm the role of multidrug-resistant *E.coli* in the dissemination of ARB&ARG across different environments.

**FEMS-2152**

**Antibiotic resistance and environment**

## **AEROMONAS SPP. AS CARRIERS OF ANTIBIOTIC RESISTANCE GENES IN HOSPITAL AND MUNICIPAL EFFLUENTS**

A.R. Varela<sup>1</sup>, O.C. Nunes<sup>2</sup>, C.M. Manaia<sup>1</sup>

<sup>1</sup>CBQF – Centro de Biotecnologia e Química Fina – Laboratório Associado, Escola Superior de Biotecnologia Universidade Católica Portuguesa/Porto, Porto, Portugal

<sup>2</sup>LEPABE - Laboratory for Process Engineering Environment Biotechnology and Energy, Faculty of Engineering University of Porto, Porto, Portugal

### **Background**

Over the last years, members of the genus *Aeromonas* have been recognized as one of the principal reservoirs of antibiotic resistance in aquatic environments. While several studies have documented the levels of antibiotic resistance associated with these bacteria in urban waterways, the contribution of hospital effluents remains unclear.

### **Objectives**

The objective of this study was to elucidate the role of this genus in the dissemination of antibiotic resistance from hospital effluent into the environment.

### **Methods**

A set of quinolone unsusceptible *Aeromonas* was isolated from untreated hospital effluent and from the inflow and treated effluent of the receiving urban wastewater treatment plant (UWTP). Isolates were identified and genotyped based on the 16S rRNA, *cpn60* and *gyrB* gene sequences. Further characterization involved determination of the antibiotic resistance phenotypes and screening for antibiotic resistance and mobile genetic elements (*qnrA,B,C,D,S,VC*; *qepA*; *oqxAB*; *aac(6')-ib-cr*; *blaOXA*; *incU*).

### **Conclusions**

The most prevalent taxonomic groups were *A. hydrophila* and *A. caviae*, found in all types of water, while *A. salmonicida* was found exclusively in the hospital effluent and raw UWTP inflow, and *A. allosaccharophyla* and *A. veronii* in the UWTP. The genetic determinants *qnrS2+incU* were a signature of the UWTP and almost absent in the hospital effluent. The genes *aac(6')-ib-cr* and *blaOXA* were distributed in isolates from all sources. The dynamics of resistance genes and mobile genetic elements was evidenced by the fact that closely related isolates harbored different combinations of those genetic elements. This observation highlights the role of *Aeromonas* as important carriers of antibiotic resistance genes in aquatic environments.

#### **CULTIVABLE GRAM-NEGATIVE BACTERIA IN DRINKING WATER: UBIQUITY, PERSISTENCE AND ANTIMICROBIAL RESISTANCE**

I. Vaz-Moreira<sup>1</sup>, O.C. Nunes<sup>2</sup>, C.M. Manaia<sup>1</sup>

<sup>1</sup>CBQF – Centro de Biotecnologia e Química Fina,  
Escola Superior de Biotecnologia Universidade Católica Portuguesa/Porto, Porto,  
Portugal

<sup>2</sup>LEPABE Laboratório de Engenharia de Processos Ambiente Biotecnologia e Energia,  
Faculdade de Engenharia Universidade do Porto, Porto, Portugal

#### **Background**

To achieve required standards of quality and safety, in most world regions, drinking water must undergo purification and disinfection processes prior to its distribution. However, tap water is colonized by a myriad of bacteria comprising those that survive disinfection or that enter at any stage of the distribution network. Despite the multiple factors affecting water microbiota, some bacterial groups are known to prevail in drinking water<sup>1</sup>. Good examples are given by genera of *Alpha*-, *Beta*- and *Gamma-Proteobacteria*, some of which display high levels of antibiotic resistance.

#### **Objectives**

The objective of this study was to characterize the diversity of cultivable Gram-negative bacteria isolated from tap water, collected over nine months. The aim was to assess which were the most prevalent, ubiquitous and persistent groups in drinking water and to evaluate their antimicrobial resistance potential.

#### **Methods**

More than 3000 isolates recovered from the water source, the water treatment and distribution system, and from 12 household taps, were screened for Gram-negative staining (51%) and absence of repetitions (same plate and identical genotype). From this selection resulted approximately 1100 isolates that were, most of which, identified by 16S rRNA or *rpoB* gene sequence analysis. The most representative groups occurring in tap water were characterized for their antimicrobial resistance phenotypes.

#### **Conclusions**

Among most ubiquitous groups were the genera *Blastomonas*, *Brevundimonas*, *Methylobacterium*, *Sphingobium*, *Sphingomonas*, *Acidovorax*, *Ralstonia*, *Acinetobacter* and *Pseudomonas*. Some of these groups comprise opportunist pathogens and present profiles of multidrug resistance, making their presence in treated drinking water an issue of concern.

**Antibiotic resistance and environment**

## **MULTIDRUG RESISTANT GRAM-NEGATIVE BACTERIA FROM HOSPITAL EFFLUENT**

I. Vaz-Moreira<sup>1</sup>, A.R. Varela<sup>1</sup>, T.V. Pereira<sup>1</sup>, R.C. Fochat<sup>1</sup>, C.M. Manaia<sup>1</sup>

<sup>1</sup>CBQF – Centro de Biotecnologia e Química Fina,  
Escola Superior de Biotecnologia Universidade Católica Portuguesa/Porto, Porto,  
Portugal

### **Background**

Hospital effluents are frequently discharged untreated in municipal collectors. However, this type of wastewater deserves a special attention given the high prevalence, and potential emerging character, of antibiotic resistance found in clinical environments.

### **Objectives**

This study aimed at identifying quinolone resistant Gram-negative bacteria with the highest multidrug resistance index (MDR) thriving in hospital effluent or in the receiving municipal wastewater treatment plant. It was aimed to assess if these bacteria may represent critical vectors for the spread of antibiotic resistance from the hospital to the environment.

### **Methods**

The criteria for inclusion in this study was to be Gram-negative, other than *Escherichia coli* and present reduced susceptibility to quinolones, a MDR phenotype (to  $\geq 6$  classes of antibiotics) or of resistance to meropenem or ceftazidime (n=25). These potential vectors of resistance were identified and characterized for antibiotic resistance phenotype, plasmid mediated quinolone resistance (PMQR) genes, presence of integron gene cassettes and conjugative capacity.

### **Conclusions**

MDR isolates comprised bacteria of the genera *Aeromonas*, *Acinetobacter*, *Citrobacter*, *Enterobacter*, *Klebsiella*, *Pseudomonas*, *Chryseobacterium* and *Myroides*. About half of these isolates had at least one PMQR gene (*aac(6')*-*Ib-cr*, *qnrB*, *qnrS* or *oqxAB*) and a class 1 integron gene cassette encoding aminoglycoside, sulfonamide or carbapeneme resistance. Some isolates, mainly *Enterobacteriaceae*, could transfer through conjugation some resistance traits. These results showed that ubiquitous bacteria, other than the groups whose monitoring in water quality controls is recommended, are important vectors of antibiotic resistance. This information is useful to support management options aiming the control of this public health problem.

### **Antibiotic resistance and environment**

#### **COUNTERACTING ANTIBIOTIC RESISTANCE IN AGRICULTURE: BIOTECHNOLOGICAL BARRIERS MIGHT DO THE TRICK**

T. Wings<sup>1</sup>, M. Busse<sup>1</sup>, B. Conde<sup>1</sup>, W. Dott<sup>1</sup>

<sup>1</sup>*Institute for Hygiene and Environmental Medicine, RWTH Aachen University, Aachen, Germany*

#### **Background**

The application of untreated manure and dung to agricultural areas provides essential fertilization for crops and pasture. However, it enables the entry of veterinary pharmacological compounds like antibiotics and heavy metals into the environment, thus promoting the distribution of resistant and potentially pathogenic microorganisms in soil, as well as ground and surface waters.

#### **Objectives**

The aim is to assess the risk of untreated agricultural wastes containing pathogens and antibiotic resistance genes on environment and human health while ascertaining the beneficial effects of manure treatment through fermentation.

#### **Methods**

Within a BMBF joint research project, we were able to monitor input and output samples of 15 German biogas plants, compiling extensive data on the chemical and microbiological status. Key organisms (e. g. Enterobacteriaceae, Enterococcaceae, Clostridiaceae) of every sample were genetically identified and archived in a strain collection to be tested for resistance and screened for tetracycline and sulphonamide resistance genes. Additionally, 4 resistance genes were quantified in all total DNA extracts and monitored in laboratory bioreactors under the influence of antibiotic supplementing over the course of 2 months.

#### **Conclusions**

Micro- and molecular biological approaches indicate a reduction of aerobic cultivable bacteria through fermentation including pathogens of the Enterobacteriaceae and Enterococcaceae without promotion of anaerobic and spore forming pathogens e.g. *Clostridium spp.* Although antibiotic resistance genes were found ubiquitously in both manure and digestate, a decline in resistance activity and resistance gene quantity after fermentation could be detected. Ultimately, biogas fermentation presents a

promising strategy to limit environmental pollution and risks for human health caused by agricultural wastes.

**Antibiotic resistance and environment**

**WIDESPREAD DISTRIBUTION OF MULTIDRUG RESISTANCE IN COMMUNITY ASSOCIATED STAPHYLOCOCCI**

Z. Xu<sup>1</sup>, H.V. Mkrtchyan<sup>1</sup>, R.R. Cutler<sup>1</sup>

<sup>1</sup>*School of Biological and Chemical Sciences, Queen Mary University of London, London, United Kingdom*

**Background**

Staphylococci are opportunistic pathogens that have emerged as a major cause of nosocomial infections. Methicillin resistance is associated with the *mecA* gene, which is located on a mobile genetic element called staphylococcal cassette chromosome *mec*(SCC*mec*). A new *mecA* homolog designated as *mecA*<sub>LGA251</sub> has been described recently.

**Objectives**

The purpose of this study was to evaluate multidrug resistant staphylococci recovered from hands of the general public.

**Methods**

267 staphylococci isolates were isolated from the general public in London, UK. All isolates were cultured, identified using MALDI-TOF-MS and tested for susceptibility to 13 antibiotics using disk diffusion method. In addition, MICs to oxacillin were also determined. *mecA* and *mecC* genes and SCC*mec* types were determined using PCR.

**Conclusions**

267 isolates belonging to 10 different staphylococcal species were recovered in this study. 223 (83.5%) staphylococcal isolates were resistant to more than two antibiotics. MICs to oxacillin varied from 0.06 mg/L to 256 mg/L. Seven out of 223 staphylococcal isolates were *mecA* positive and 3 *mecC* positive. SCC*mec* types were assigned for 4 out of 10 *mecA* and *mecC* positive strains. 2 SCC*mec* types V and 1 type VI were *mecA* positive and 1 SCC*mec* type IV was *mecC* positive.

We report on the widespread distribution of antibiotic resistant strains on the hands of the general public. We also report for the first time the isolation of *mecA* homologue *mecC* gene from randomly selected individuals. This emphasises the importance of good hygiene within the community.

**EVALUATION OF CLASS 1-3 INTEGRONS AMONG PSEUDOMONAS AERUGINOSA CLINICAL ISOLATES IN MILAD HOSPITAL, TEHRAN, IRAN**

M. Abbas<sup>1</sup>, S. Hosseini<sup>1</sup>, M. Masbi<sup>1</sup>, S. Ghafourian<sup>1</sup>, H. Valadbeigi<sup>1</sup>, A. Kamran<sup>2</sup>, S. Karami<sup>1</sup>, N. Sadeghifard<sup>1</sup>

<sup>1</sup>Clinical Microbiology Research Center,  
Ilam University of Medical Sciences Ilam Iran, Ilam, Iran

<sup>2</sup>Faculty of Medicine, Tabriz University of Medical Sciences Ilam Iran, Tabriz, Iran

**Background**

*Pseudomonas aeruginosa* is a Gram-negative opportunistic pathogen that is found in soil, water and moist environments. *P. aeruginosa* infections are major cause of hospital morbidity and mortality.

**Objectives**

The current study aimed to demonstrate the frequency of class 1, 2 and 3 integrons in *P. aeruginosa* clinical isolates collected from urinary tract infections in Milad Hospital, Tehran, Iran.

**Methods**

Sixty *P. aeruginosa* strains were isolated from urinary tract infections during period December to March 2012. Antibiotic susceptibility testing was performed by disk diffusion method according to CLSI. Then, DNA of isolates were extracted and the presence of class 1, 2 and 3 integrons were examined by PCR.

**Conclusions**

**Results:** The antibiotic susceptibility pattern of *P. aeruginosa* clinical isolates were as follows: resistance to cefepime, ceftriaxone, Aztreonam, gentamicin, amikacin, ciprofloxacin, ofloxacin, ceftazidime, piperacillin tazobactam, and imipenem were 73.3%, 40%, 51.6%, 31.7%, 26.6%, 43.3%, 45%, 35%, 23.3%, and 15%, respectively. Based on our analysis, 73.3% and 1.6% of *P. aeruginosa* clinical isolates were positive int-1 and int-2, respectively. The negative results obtained for int-3.

**Conclusion:** Our findings demonstrated high frequency of class I integron in *P. aeruginosa* clinical isolates and therefore, the class I integron might play a special role in transfer of antibiotic resistant genes

**FEMS-0492**

**Antimicrobial resistance**

**PHENOTYPIC DETECTION OF EFFLUX PUMPS IN MULTI-DRUG RESISTANT PSEUDOMONAS AERUGINOSA ISOLATED FROM SUEZ CANAL UNIVERSITY HOSPITAL**

O. Aboulola<sup>1</sup>, A. Bakeir<sup>1</sup>, N. Gomaa<sup>1</sup>, W. Hessam<sup>1</sup>

<sup>1</sup>Microbiology and Immunology, Faculty of Medicine Suez Canal University, Ismailia, Egypt

**Background**

Infections caused by *Pseudomonas aeruginosa* are often severe, life threatening and difficult to treat because of the limited susceptibility to antimicrobials, the high frequency of emergence of antibiotic resistance during therapy and the emergence of multi-drug resistant (MDR) strains that develop resistance by various mechanisms including efflux pumps. Efflux pumps contribute to multidrug resistance by expelling antibiotics out of cells.

**Objectives**

Detection of the role of efflux pumps in MDR *Pseudomonas aeruginosa* isolates from Suez Canal university hospital in Ismailia.

**Methods**

The study included 49 *Pseudomonas aeruginosa* strains isolated from 307 nosocomially infected patients. Antibiotic susceptibility tests were done by disc diffusion method. For detection of association of efflux pumps, strains proved to be MDR were further tested for minimal inhibitory concentration (MIC), using the agar dilution susceptibility method, of four antibiotics of different groups (ciprofloxacin, meropenem, cefotaxime and gentamicin) before and after addition of the efflux pump inhibitor carbonyl cyanide m-chlorophenyl hydrazone (CCCP).

**Conclusions**

Using disc diffusion, 28 strains (57.1%) were proved to be MDR. The efflux pumps-associated resistance was proved through reduction of MIC in 18 (64.3%) , but not in 10 (35.7), of the MDR strains for ciprofloxacin and meropenem: 7 strains for ciprofloxacin, 7 for meropenem and 4 strains for both drugs together. This approximately twice association suggests a role of efflux pumps in MDR *Pseudomonas aeruginosa*. Understanding the mechanisms by which these pumps

act and how to overcome its activity opens the door for restoring the antibiotic activity and constitute a promising target for novel antibacterial agents.

## FEMS-2214

### Antimicrobial resistance

#### FIRST DESCRIPTION IN EUROPE OF A CIPROFLOXACIN RESISTANT *SALMONELLA* TYPHIMURIUM HARBOURING AAC6'-IB-CR AND OQXAB IN AN INCHI2 PLASMID

J. Campos<sup>1</sup>, S. Marça<sup>2</sup>, J. Mourão<sup>1</sup>, J. Machado<sup>3</sup>, C. Novais<sup>1</sup>, P. Antunes<sup>4</sup>, L. Peixe<sup>1</sup>

<sup>1</sup>Laboratório de Microbiologia,

UCIBIO/REQUIMTE Faculdade de Farmácia Universidade do Porto, Porto, Portugal

<sup>2</sup>Laboratório de Microbiologia,

Faculdade de Ciências da Nutrição e Alimentação Universidade do Porto, Porto, Portugal

<sup>3</sup>Departamento de Doenças Infeciosas,

Instituto Nacional de Saúde Dr. Ricardo Jorge, Lisboa, Portugal

<sup>4</sup>Laboratório de Microbiologia,

Faculdade de Ciências da Nutrição e Alimentação Universidade do Porto. UCIBIO/R EQUIMTE Faculdade de Farmácia Universidade do Porto, Porto, Portugal

#### Background

Fluoroquinolones are critical antibiotics (AB) for the treatment of *Salmonella* non-typhoid infections. Plasmid-mediated quinolone resistance (PMQR) genes have been often associated with decreased susceptibility to these AB worldwide, but concomitant presence of *oqxAB* and *aac6'-lb-cr* genes, increasingly described in Asia, is still scarce in Europe.

#### Objectives

To characterize the genetic background (clonality, AB resistance genes, their transferability and genetic environment) of ciprofloxacin resistant *S.Typhimurium* clinical isolates.

#### Methods

Two clinical isolates of *S.Typhimurium* resistant to ciprofloxacin [young children (feaces)/one hospital/2012/Portugal] were studied. Susceptibility to AB and detection of ESBL were assessed by disk diffusion and/or Etest methods (CLSI/EUCAST). Characterization of AB resistance genes, including topoisomerases (*gyrA/gyrB/parC/parE*) and PMQR [*qnrA/qnrB/qnrC/qnrD/qnrS/qepA/aac(6')-lb-cr/oqxAB*] genes, and metals (copper/silver/mercury/arsenic/tellurite) tolerance genes was performed (PCR/sequencing). Clonality (*Xba*I-PFGE/MLST), class 1 integron, plasmid characterization (PCR/sequencing), conjugation/transformation assays and genomic location (*I-Ceu*II/S1-PFGE hybridization) were also performed.

#### Conclusions

Presence of multidrug-resistant IncHI2-~180Kb plasmid encoding *oqxAB* and *aac-6'-lb-cr* in a ciprofloxacin resistant *S.Typhimurium*/ST34, also carrying *gyrA* mutation (Asp87Asn), is here firstly described in Europe. Co-resistance to nalidixic acid,

chloramphenicol-*cmlA/floR/catB3*, gentamicin-*aac(3)-IV*, kanamycin-*aphA1*, streptomycin-*aadA/strA-strB*, sulfamethoxazole-*sul1/sul2/sul3*, tetracycline-*tetB*, trimethoprim-*dfrA12*, ampicillin-*bla<sub>TEM</sub>/bla<sub>OXA-1</sub>* and genes coding for metals tolerance (*merA/silA/pcoD/terF*) were found. Transformation of PMQR carrying plasmid was associated with resistance acquisition to several antibiotics (*cmlA/floR/catB3/aac(3)-IV/aphA1/aadA/sul1/sul2/sul3/dfrA12/bla<sub>OXA-1</sub>*) and an eight-fold increase on ciprofloxacin MIC. Interestingly, the IncHI2 plasmid carried *oqxAB* genes flanked by IS26 and an incomplete class 1 integron containing *aac-6'-lb-cr-bla<sub>OXA-1</sub>-catB3-arr3-qacEΔ1-sul1*, atypical *sul3*-integron and *terF*. A similar PMQR genetic environment in *Salmonella* with IncHI2 circulating in Asia was observed, highlighting the role of these plasmids in *oqxAB* and *aac-6'-lb-cr* global spread.

**ASSESSMENT OF MULTIPLE ANTIBIOTIC RESISTANT ENTEROCOCCI IN COMMERCIAL AND COMMUNAL CATTLE FAECES AND THEIR WATER SOURCES IN MAFIKENG, NORTH-WEST PROVINCE, SOUTH AFRICA**

C. Ateba<sup>1</sup>, C.C. Bezuidenhout<sup>2</sup>, L.L.N. Ramatlhape<sup>3</sup>

<sup>1</sup>Molecular Microbiology Laboratory Department of Biological Sciences, North West University -Mafikeng Campus, Mmabatho, South Africa

<sup>2</sup>Microbiology Division School of Environmental Science and Development, North West University -Potchefstroom Campus, Potchefstroom, South Africa

<sup>3</sup>Centre for Animal Health Studies, North West University -Mafikeng Campus, Mmabatho, South Africa

**Background**

Enterococci are part of the intestinal microflora of most mammals.

**Objectives**

To isolate and determine the antibiotic resistance profiles of *Enterococcus* species from cattle farms in South Africa

**Methods**

A total of 49 faecal and 16 water samples from 2 commercial farms (Molelwane and Rooigrond) and a communal farm (Gelukspan) were analysed for *Enterococcus* species. 138 potential isolates were obtained and 129 enterococci were positively identified. All the 129 isolates were subjected to antibiotic susceptibility tests. The antibiotic inhibition zone diameter data of the isolates were subjected to cluster analysis and the results expressed as dendrograms. Vancomycin and tetracycline specific PCR was also performed.

**Conclusions**

*Enterococcus avium* (61%) and *Enterococcus faecium* (32%) were the dominant species isolated from both diarrhoeal and healthy cattle compared to *Enterococcus durans* (5%) and *S. bovis* (2%). Only *Enterococcus avium* (13.9%) and *Enterococcus faecium* (10.1%) were isolated from water samples. Large proportion (30%) of the isolates were resistant to tetracycline compared to vancomycin (17%). The MAR phenotype GM-SMX-NAL-NIT-C-K-S was dominant (38%) among *E. faecium* isolated from communal and commercial cattle while GM-SMX-NAL-NIT-K-S was dominant among *E. faecium* (40%), *E. durans* (60%) and *E. avium* (42%) isolated healthy and diarrhoeal cattle in both the communal and commercial farms. None of the enterococci isolates were positive for the *vanA* and *vanB* genes but the *vanC* gene was detected in 20% and 1.6% of *E. durans* and *E. avium*, respectively. Cluster analysis could not distinguish between isolates from commercial and communal farms indicating that these isolates had similar antibiotic resistant profiles.

**MOROCCAN BIOACTIVE ACTINOBACTERIA ISOLATES PRODUCING EFFLUX PUMPS INHIBITORS (EPI) OF RESISTANT BACTERIA**

A. azmani<sup>1</sup>, A. Nafis<sup>1</sup>, L. Hassani<sup>1</sup>, M. Barakate<sup>1</sup>

<sup>1</sup>biologie, Cad Ayad univerty, Marrakech, Morocco

**Background**

Traditional antimicrobials antibiotics are increasingly suffering from the emergence of multidrug resistance among pathogenic microorganisms. Among the antibiotic resistance mechanisms, efflux pumps have recently received a particular attention. Hence, there is an acute need for new active agents.

**Objectives**

Reducing the rate of emergence of antibiotic-resistant is our objective by studying the ability of Moroccan actinobacteria isolates to produce natural efflux pumps inhibitors (EPI) of medical interest

**Methods**

210 actinobacteria isolates were screened for their ability to produce efflux pumps inhibitors using agar diffusion method. As test strains we have used in this study the wild type strain *E. coli* AG100 and its mutant AG100A with non- functional pump efflux system and the two clinical strains of *S.aureus*: the sensitive one SA-1199 and its mutant SA1199B. Phe-Arg- $\beta$ -naphtylamide (PA $\beta$ N) which inhibits the efflux system of many bacteria was used as control. Finally the biological and chemical characterizations of active compounds were conducted from four liters fermentation culture of selected bioactive.

**Conclusions**

Our screening program showed that among the 210 screened actinobacteria isolates, 9% were able to produce EPI. From the most promising ones we have purified five different bioactive compounds and their structure elucidation were under investigation. Screening only a subsection of our natural product library led to purify five molecules as EPI capable of sensitizing Gram-negative and Gram positive bacteria to antibiotics to which they are ordinarily intrinsically resistant. This result demonstrates the great potential of this approach in expanding antibiotic effectiveness in the face of the growing challenge of resistance

## **FEMS-2292**

### **Antimicrobial resistance**

#### **IN VITRO ACTIVITIES OF SEVEN ANTIFUNGAL DRUGS AGAINST CANDIDA AFRICANA, AN ATYPICAL AGENT OF VULVOVAGINAL CANDIDIASIS**

B. Badali<sup>1</sup>, H. Fakhim<sup>1</sup>

<sup>1</sup>Department of Medical Mycology,

Invasive Fungi Research Center Mazandaran University of Medical Sciences Sari, Sari, Iran

### **Background**

Vulvovaginal candidiasis (VVC) is a common vaginal fungal infection, affecting 70–75% of young women at least once during their lifetime. *Candida africana* is an opportunistic yeast pathogen that was proposed as a new species within the *C. albicans* species complex in 2001. It has been reported from 12 countries predominantly as an agent of VVC. Although, recently a large variety of antifungal drugs are used for treatment of VVC, treatment is a big challenge.

### **Objectives**

Therefore in the present investigation, we evaluated the in vitro antifungal susceptibility testing of 7 agents against *C. africana* isolated from vulvovaginitis patients

### **Methods**

5 strains out of 350 vaginal swabs were identified as *C. africana* based molecular methods. The MIC of AmB, FLU, ITC, VOR, POS, ISA, MICA, ANID were determined based on CLSI document M27-A3.

### **Conclusions**

The isolates were susceptible to Amphotericin B (MIC= 0.25 µg/ml), fluconazole (MIC= 1 µg/ml), itraconazole (MIC range, 0.5 - <0.016), voriconazole (MIC range, 0.5 - <0.016), posaconazole (MIC range, 0.5 - <0.016), isavuconazole (MIC range, 0.5 - <0.016), micafungin (MIC range, 0.016 - <0.008), anidulafungin (MIC range, 0.031 - <0.008).

*C. africana* has been largely associated with superficial infections of the genital tract, despite it has been associated with deep-seated infections, suggesting its invasive potential. The global patterns of resistance/susceptibility to most antifungal drugs remain largely unknown in *C. africana*; However high MIC of voriconazole, flucytosine and terbinafine against *C. africana* has been demonstrated. Antifungal susceptibility testing should be determined before therapy to avoid treatment failures.

<sup>2</sup>Ophthalmology, Istanbul University Cerrahpasa School of Medicine, Istanbul, Turkey

<sup>3</sup>4th grade student, Trakya University School of Medicine, Istanbul, Turkey

<sup>4</sup>Medical Microbiology, Bahcesehir University Medical Faculty, Istanbul, Turkey

#### Background

*Propionibacterium acnes* can cause invasive deep seated infections, usually in the setting of implantable devices and its antimicrobial resistance is beginning to emerge.

#### Objectives

*P.acnes* can act as an opportunistic pathogen causing invasive and chronic biomaterials-associated infection through a biofilm mode of growth. In this study we aimed to review the frequency and the antimicrobial resistance of *P. acnes* in infections involving implants.

#### Methods

From March 2011 to April 2014, cerebrospinal fluid specimens (CFS) of 46 patients with internal shunt infection (ISI), corneal scrapings (CS) of 55 patients with delayed postoperative endophthalmitis (DPE) developed after lens implantation, periprosthetic tissues (PT) of 11 patients with prosthetic shoulder infection (PSI) and 17 patients with prosthetic joints infection (PJI) were studied. Samples were inoculated on supplemented Schaedler agars and fluid thioglycolate medium and were incubated during 15 days in anaerobic jars (Oxoid) on anaerobic conditions. Anaerobic bacteria were identified by API 20 A (BioMerieux). Susceptibility testing for penicillin, ampicillin+sulbactam, cefoxitin, clindamycin, tetracycline, rifampicin was performed with E-test (BioMerieux).

#### Conclusions

*P.acnes* was isolated from 2(4,3%) CFS, 16(29%) CS, 1(9 %) PT sample of patients with PSI and from 2(11.7%)PT samples of patients with PJI. These 21 *P.acnes* strains were susceptible to penicillin, ampicillin+sulbactam, cefoxitin and rifampicin whereas 38% (8/21) were resistant to clindamycin (MIC 90:32 mg/L), 14.2% (3/21) were resistant to tetracycline (MIC90: 4 mg/L). *P.acnes* is most frequently found in CS of patients with DPE developed after lens implantation. Its increasing clindamycin and tetracycline resistance should be taken into consideration during the treatment of biomaterials-associated infection.

## **FEMS-1004**

### **Antimicrobial resistance**

#### **ANTIBIOTIC SUSCEPTIBILITIES OF PSEUDOMONAS AERUGINOSA AND ACINETOBACTER BAUMANII IN A TERTIARY TRAINING HOSPITAL WITHIN EIGHT YEARS PERIOD**

*B. BEKTORE*<sup>1</sup>, *O. BAYLAN*<sup>1</sup>, *M.B. SELEK*<sup>1</sup>, *T. HOSBUL*<sup>1</sup>, *T. KULA ATIK*<sup>1</sup>,  
*U. KARAKAS*<sup>1</sup>, *M. OZYURT*<sup>1</sup>

<sup>1</sup>*Medical Microbiology,*

*Gulhane Military Medical Academy Haydarpasa Training Hospital, Istanbul, Turkey*

### **Background**

Gram negative non-fermenting bacteria related infections are among the major problems encountered in health care facilities. *Pseudomonas aeruginosa* and *Acinetobacter baumannii* are common and widely distributed non-fermenter pathogens which mostly cause opportunistic and nosocomial infections in patients at intensive care units as well as general wards.

### **Objectives**

In this retrospective study, we aimed to present antimicrobial susceptibility trends of common non-fermenters (*P.aeruginosa* and *A.baumannii*) in a tertiary referral hospital in Istanbul, Turkey. All chosen antimicrobial agents are consistently tested during study period, which covers eight years from 2006 to 2013.

### **Methods**

All *P.aeruginosa* (n:1312) and *A.baumannii* (n:1809) isolates from various specimens of inpatients from various clinics including ICUs were tested for antibiotic susceptibility for certain agents, between January 2006 and December 2013. Isolates were identified by conventional methods and/or commercial identification systems - API 20 NE (2006-2007) and VITEK 2 (2007-20013). Susceptibility testing of non-fermenters (n:3121) is performed by Kirby-Bauer disc diffusion method and results are interpreted according to CLSI guidelines.

### **Conclusions**

Multidrug resistance in *P.aeruginosa* and *A.baumannii* is a worldwide problem. The key point of our study is the demonstration of antibiotic susceptibilities of *P.aeruginosa* and *A.baumannii* isolates with more than 3000 isolates within a long period of eight years within our tertiary training hospital. Increasing carbapenem resistance is a major problem in our setting especially for *A.baumannii* strains. Among

tested aminoglycosides, tobramycin is found more effective than amikacin for *A.baumannii*. Quinolones were found quite effective against *P.aeruginosa in vitro* and even more effective than carbapenems for some years. But resistance rates were found very high against *A.baumannii*.

**FEMS-2143**

**Antimicrobial resistance**

## **FUSIDIC ACID AND MUPIROCIN RESISTANCE RATES AMONG STAPHYLOCOCCUS AUREUS CLINICAL ISOLATES**

T. Hosbul<sup>1</sup>, B. Bektore<sup>2</sup>, T. Kula Atik<sup>2</sup>, M.B. Selek<sup>2</sup>, O. Baylan<sup>2</sup>, M. Ozyurt<sup>2</sup>

<sup>1</sup>Medical Microbiology, Golcuk Military Hospital, Izmit, Turkey

<sup>2</sup>Medical Microbiology, GATA Haydarpaşa Training Hospital, Istanbul, Turkey

### **Background**

*Staphylococcus aureus* is one of the major pathogens causing infections both in community and in health care settings. Both mupirocin and fusidic acid are topical antimicrobial agents that can be used for the treatment of staphylococcal skin infections and/or elimination of its nasal carriage.

### **Objectives**

We aim to determine high level (HL) mupirocin resistance and *in vitro* activity of fusidic acid in clinical *S. aureus* strains isolated between 2011 and 2013.

**Figure.** Gel electrophoresis of PCR products of *ileS2* gene. M: 100-bp DNA ladder; NC: negative control; PC: positive control; Lines 1, 2, 3, 4, 5 indicate *ileS2* positive isolates respectively.

### **Methods**

A total of 208 *S. aureus* strains, 86 methicillin resistant *S. aureus* (MRSA) and 122 methicillin susceptible *S. aureus* (MSSA), were tested for HL mupirocin with a 200 µg disc according to the CLSI guidelines. Fusidic acid resistance was investigated by 10 µg disc according to the criteria of EUCAST. HL mupirocin resistance was also confirmed by PCR for *ileS2* gene by using “*ileS2*-M1 5’ GTTTATCTTCTGATGCTGAG 3’ and *ileS2*-M2 5’ CCCCAGTTACACCGATATAA 3’” primers. Resistance to mupirocin and fusidic acid were found as 7.2% (15/208) and 17.8% (37/208). Resistance rates of mupirocin for MRSA and MSSA were detected

as 15.1% (13/86) and 1.6% (2/122). Resistance rates of fusidic acid for MRSA and MSSA were determined as 25.6% (22/86) and 12.3% (15/122).

### **Conclusions**

We detected lower resistance rates for mupirocin than fusidic acid among clinical *S. aureus* strains in our hospital. Today increased topical preparations and inappropriate clinical use of antibiotics seem major factors causing to resistance and clonal selection. Prescription of topical mupirocin or fusidic acid especially for prolonged treatment of skin infections and for decolonization of *S. aureus* from nares should be reconsidered.

<sup>3</sup>Pediatric Infectious Diseases, Radboud University Medical Centre, Nijmegen, Netherlands

<sup>4</sup>Unidad de Cristalografía de Macromoléculas, Instituto de Biomedicina de Valencia-Consejo Superior de Investigaciones Científicas, Valencia, Spain

#### Background

*Streptococcus suis* is a major bacterial pathogen of swine, causing high mortality and economic losses worldwide. *S. suis* is also emerging as an important cause of meningitis in humans in South East and East Asia. Antibiotic resistance of *S. suis* clinical isolates has been reported worldwide.

#### Objectives

Identification of novel antimicrobial drug targets of *S. suis* and validation of some of these targets.

#### Methods

Essential genes of *S. suis* S10 have been identified in a high-throughput genome-wide screen using a mariner transposon insertion approach (Tn-Seq). We constructed a list of *S. suis* S10 essential genes based on Tn-Seq results and published lists of orthologous essential genes of three Gram-positive bacteria. Based on this we selected several putative drug targets. We generated conditionally knock-out of *yycF/G* to elucidate its regulatory network and to validate its essentiality.

#### Conclusions

1) Genome-wide screening of a transposon insertion library of *S. suis* S10 revealed 281 essential genes of which 54 genes were shared with three other Gram-positive bacteria. 2) *yycF/G* was the only essential Two-component System in four selected Gram-positive bacteria. 3) A conditional knock-out strain of *yycF/G* in *S. suis* S10 validated its essentiality and potential as a drug target for novel antimicrobials.

## **FEMS-2010**

### **Antimicrobial resistance**

#### **ANTIFUNGAL RESISTANT YEAST FROM THE HARTS RIVER, SOUTH AFRICA**

M.E. Monapathi<sup>1</sup>, O.H. Rhode<sup>2</sup>, C. Bezuidenhout<sup>1</sup>

<sup>1</sup>Microbiology, North-West University, Potchefstroom, South Africa

<sup>2</sup>Grain Crops Institute, Agricultural Research Council, Potchefstroom, South Africa

#### **Background**

Yeast species identified in a previous study in the North West Province are associated with superficial mucosal infections and life-threatening diseases. Treatment is by available antifungal drugs. Due to continuous exposure of aquatic yeast species to sub-therapeutic levels of antifungal agents, these species have developed resistance.

#### **Objectives**

The aim of this study was to determine the diversity and antifungal susceptibility patterns of yeasts in the Harts River of the North West Province, South Africa.

#### **Methods**

Yeast colonies were enumerated using yeast-malt-extract (YM) agar (containing 100 ppm chloramphenicol). Purified isolates from 37°C incubation were identified by biochemical tests and 26S rRNA gene sequencing. Disc diffusion antifungal susceptibility tests were conducted on the yeast species.

#### **Conclusions**

Yeasts levels ranged between 320-4200 cfu/L and 27-2573 cfu/L for room temperature and 37°C. All the yeast colonies isolated were non-pigmented. DBB tests determined the yeasts isolates as ascomycetes. Yeasts isolates were identified and belonged to the genera *Arxiozyma*, *Candida*, *Clavispora*, *Cyberlindnera*, *Lecythophora*, *Pichia*, *Saccharomyces*, and *Wickerhamomyces*. *Saccharomyces cerevisiae* and *Candida glabrata* were most frequently isolated species. A large number of isolates were resistant to azoles, especially fluconazole as well as other antifungal classes. Most of the *Candida* species were resistant to almost all the antifungals. Several of the isolated yeast species are opportunistic pathogens. These could cause infections in sensitive individuals during occasional direct contact. A major health concern is that these infections may not respond to available antifungal agents.

#### C. PARAPSILOSIS AZOLE RESISTANCE CONFERRED BY A GAIN-OF-FUNCTION MUTATION IN MRR1 TRANSCRIPTION FACTOR

J. Branco<sup>1</sup>, A. Pinto-Silva<sup>2</sup>, R. Silva<sup>3</sup>, A. Silva-Dias<sup>4</sup>, C. Pina-Vaz<sup>4</sup>, A. G. Rodrigues<sup>4</sup>, G. Butler<sup>5</sup>, I. M. Miranda<sup>2</sup>

<sup>1</sup>Microbiology, Faculty of Medicine of the University of Porto, Porto, Portugal

<sup>2</sup>Microbiology and CINTESIS, Faculty of Medicine of the University of Porto, Porto, Portugal

<sup>3</sup>IPATIMUP, University of Porto, Porto, Portugal

<sup>4</sup>Microbiology and CINTESIS, Faculty of Medicine of the University of Porto, Porto, Portugal

<sup>5</sup>Biomolecular and Biomedical Science, University College Dublin, Dublin, Ireland

#### Background

The human fungal pathogen, *Candida parapsilosis*, is mostly isolated from patients with bloodstream infections and its incidence in some countries is equal or exceeds that of *C. albicans*. For the treatment of these infections, azoles are widely used as prophylactic and therapeutic drugs. However, *C. parapsilosis* clinical azole resistance has been increasing in the last decade and little is known about the antifungal resistance mechanisms involved in the development of such resistance. Recently, voriconazole resistance mechanisms were associated with *MDR1* (encoding for a multidrug efflux pump) and *MRR1* (transcription factor) genes overexpression. Furthermore, a mutation in the *MRR1* gene (A2619C) that resulted in an alteration of lysine to asparagine, K873N, in polypeptide chain was firstly reported.

#### Objectives

Knowing that gain-of-function mutations found in transcription factors genes play a crucial role in azole resistance acquisition, we intend to elucidate the importance of A2619C mutation in *MRR1* gene in *C. parapsilosis* azole resistance.

#### Methods

For that, *MRR1*<sub>R<sub>VR</sub></sub> mutated gene was integrated in its native locus in a double deleted strain,  $\Delta mrr1/\Delta mrr1$ . Azole susceptibility and gene expression profile of the set of strains used in this study were characterized.

#### Conclusions

The *MRR1*<sub>R<sub>VR</sub></sub> complemented strain changed azole susceptibility profile, from susceptible to resistant, and also displayed an up regulation of *MRR1* and *MDR1* genes. Thus, missense mutation A2619C described in *MRR1* transcription factor is a

gain of function mutation, decisive for azole resistance.  
This study was supported by FEDER, COMPETE and FCT (PTDC/DTP-EPI/1660/2012).

#### **SURVEILLANCE OF CANDIDA PARAPSILOSIS ANTIFUNGAL RESISTANCE**

J. Branco<sup>1</sup>, R. Silva<sup>2</sup>, A. Silva-Dias<sup>3</sup>, C. Martins-Cruz<sup>1</sup>, E. Fonseca<sup>1</sup>, C. Pina-Vaz<sup>3</sup>, A. G. Rodrigues<sup>3</sup>, T. Gonçalves<sup>4</sup>, I. M. Miranda<sup>3</sup>

<sup>1</sup>Microbiology, Faculty of Medicine of the University of Porto, Porto, Portugal

<sup>2</sup>IPATIMUP, University of Porto, Porto, Portugal

<sup>3</sup>Microbiology and CINTESIS, Faculty of Medicine of the University of Porto, Porto, Portugal

<sup>4</sup>Center for Neurosciences and Cell Biology, Faculty of Medicine of the University of Coimbra, Coimbra, Portugal

### **Background**

In Portugal, *C. parapsilosis* is the second most common yeast specie isolated from patients with bloodstream infections. However, *C. parapsilosis* increasing prevalence was been found in other European countries and in Latin America and Asia. Azoles are widely used as prophylactic and therapeutic drug; but *C. parapsilosis* acquires azole resistance in a rapid and stable manner.

### **Objectives**

This study aims to characterize antifungal susceptible profile of *C. parapsilosis* sensu stricto etiologic agent of human infections from two major Portuguese hospitals, Centro Hospitalar de Coimbra and Centro Hospitalar São João and uncover the molecular mechanisms underlying antifungal resistance.

### **Methods**

Clinical isolates (n=93) collected from distinct body sites/products were depicted regarding antifungal susceptibility profile to azoles (fluconazole, voriconazole, posaconazole) and echinocandins (caspofungin, micafungin, anidulafungin). The minimal inhibitory concentration (MIC) of each antifungal drug was determined according to the M27-A3 protocol of the Clinical and Laboratory Standard Institute. Gene expression profile of the resistant isolates was carried out by RT-PCR.

### **Conclusions**

Among *C. parapsilosis* isolates, 10% were resistant to fluconazole; 6% were resistant to voriconazole and 2% were resistant to posaconazole. The incidence of susceptible–dose-dependent found was 6% for FLC and 10% for VRC. No resistance was found for echinocandins. Azole resistance development was mainly associated with *MDR1* (encoding multidrug efflux pump) and *MRR1* (transcription factor that

regulates *MDR1* expression) genes overexpression. Our study showed that prevalence of azole *C. parapsilosis* resistant isolates has increased dramatically since the last survey carried out in 2009. This study was supported by FEDER, COMPETE and FCT (PTDC/DTP-EPI/1660/2012).

## **IMPACT OF THE MUTATIONS IN DNA GYRASE GENES ON QUINOLONE RESISTANCE IN *CAMPYLOBACTER JEJUNI***

R. Changkwanyee<sup>1</sup>, S. Kongsoi<sup>1</sup>, K. Changkaew<sup>1</sup>, K. Yokoyama<sup>2</sup>, H. Kim<sup>3</sup>,  
O. Suthienkul<sup>4</sup>, C. Nakajima<sup>1</sup>, Y. Suzuki<sup>1</sup>

<sup>1</sup>Bioresources, Hokkaido University Research Center for Zoonosis Control, Sapporo, Japan

<sup>2</sup>Central Research Laboratory, Kissei Pharmaceutical Co. Ltd, Azumino, Japan

<sup>3</sup>Bacteriology II, Bacteriology II National Institute of Infectious Diseases, Musashi Murayama, Japan

<sup>4</sup>Public Health, Thammasat University, Bangkok, Thailand

### **Background**

*C. jejuni* has shown increasing resistance to quinolone. The resistance is mediated by a point mutation in the quinolone resistance-determining region (QRDR) of *gyrA* with the high frequency at position 86, followed by position 90. However, no direct evidence of the association between these mutations and the quinolone resistance has been shown to date.

### **Objectives**

To clarify the impact of an amino acid substitution at positions 86 or 90 in *C. jejuni* GyrA on DNA gyrase activity in the presence or absence of quinolones

### **Methods**

The recombinant DNA gyrases with amino acid substitutions at position 86, and 90 in GyrA were expressed in *Escherichia coli* and purified using Ni-NTA agarose column chromatography. Wild-type and mutant DNA gyrases were reconstituted *in vitro* by mixing recombinant GyrA and GyrB. Correlation between the amino acid substitution and quinolones resistance was assessed by quinolone-inhibited supercoiling assay.

### **Conclusions**

The quinolone-inhibited supercoiling assay demonstrated the important role of these amino acid substitutions in reduced sensitivity to quinolone with mark influence by amino acid substitution, especially Thr86Ile. This study confirmed the association of these mutations with the quinolone resistance in *C. jejuni* and demonstrated that sitafloxacin might be a candidate for the treatment of campylobacteriosis caused by ciprofloxacin-resistant *C. jejuni*.

**CLASS 1 INTEGRON-INTEGRASE ACTIVITY AND BACTERIAL SOS RESPONSE  
IN A MOUSE MODEL**

M. BALTAZAR<sup>1</sup>, N. BOURGEOIS-NICOLAOS<sup>2</sup>, F. DOUCET-POPULAIRE<sup>2</sup>,  
M.C. PLOY<sup>1</sup>, S. DA RE<sup>1</sup>

<sup>1</sup>87000, Université de Limoges INSERM UMR-S1092 CHU de Limoges, Limoges,  
France

<sup>2</sup>92296, Université Paris-Sud EA 4043, Chatenay-Malabry, France

**Background**

The bacterial SOS response to DNA damages is involved in antibiotic resistance acquisition and dissemination. It can regulate expression of resistance genes (eg *qnrB*), or acquisition of resistance genes (eg expression of the integrase of integrons, *IntI*). Integrons are genetic elements that play a major role in the dissemination of antibiotic resistance in Gram-negative bacteria. *IntI* catalyses insertion and excision of resistance genes embedded within gene cassettes. Dissemination of resistance genes might also be correlated to the SOS response as shown for bacterial conjugation. Various stresses including antibiotics can induce the SOS response.

**Objectives**

Our aim was to estimate the level of the SOS response and of the *IntI* expression and activity *in vivo* in the mouse digestive tract.

**Methods**

Germ-free mice were inoculated intragastrically with a strain of *Escherichia coli* carrying two plasmids: one harbouring the *intI1* gene under the control of its own promoter, the second containing a gene cassette array. Efficiency of bacterial colonisation, plasmid stability and *IntI1* activity were estimated from mice feces. *intI1* and *sfiA* (SOS regulon) genes expression level was estimated by qPCR.

**Conclusions**

We observed a higher expression of the SOS response and of *IntI1* *in vivo* than *in vitro* and a 1.5 log increase of the *IntI1* excision frequency.

Our results indicate that the digestive tract is an environment where the SOS response is induced. Moreover, the higher expression and activity of integrase highlight the role of the gut in disseminating antibiotic resistance.

<sup>4</sup>Department of Periodontology Dental Research Division, University of Guarulhos, São Paulo, Brazil

<sup>5</sup>Department of clinical microbiology, Hospital Beneficência Portuguesa, São Paulo, Brazil

#### Background

Linezolid is an oxazolidinone antimicrobial agent for treating infections caused by multi-drug resistant Gram-positive cocci. Mutations in domain V of 23S rRNA, an adenosine modification catalyzed by Cfr and mutations in the ribosomal proteins L3, L4 and L22 are mechanisms that have emerged in linezolid-resistant isolates. We identified a clinical *Staphylococcus haemolyticus* strain (ShRL1) exhibiting a high level of minimum inhibitory concentrations (MIC, 64µg/mL) for linezolid, which did not show any of these mechanisms. Moreover, the ShRL1 strain shows genes encoding proteins of the ATP-binding cassette (ABC) superfamily which were not identified in its susceptible derivative ShSL2 (MIC, 1µg/mL) after 7 subcultures under no selective antibiotic pressure.

#### Objectives

To compare the whole genome sequencing of the ShRL1 and ShSL2 strains in order to determine a cause of linezolid resistance.

#### Methods

Genome sequencing was performed using the Ion Torrent<sup>®</sup> PGM platform (Life Technologies) kit400bp. The sequences were de novo assembled using Mira v4.0.2 and spades v3.1.1. Scaffold was obtained using CLC Genomics Workbench v7.5 and Geneious 8.0.5 with the genome reference *S. haemolyticus* JCSC1435. Lastly comparative analyses were performed using Mauve v3.2.

#### Conclusions

Rare studies have associated efflux-pump systems with linezolid decreased susceptibility. We propose a resistance mechanism other than target site modifications that may be responsible for elevated MIC for linezolid in *S. haemolyticus*. Further studies are necessary to support it. However, our data strongly suggest that the ATP-binding cassette (ABC) system, which share about 70% sequence homology to efflux proteins of *S. aureus*, has an important role in linezolid resistance in *S. haemolyticus*.

**Antimicrobial resistance**

## **THE ANTIBACTERIAL EFFICACY OF DIFFERENT MOUTHRINSES ON PERIODONTAL PATHOGENS**

E. Decker<sup>1</sup>, V. Bartha<sup>1</sup>, C. von Ohle<sup>1</sup>

<sup>1</sup>*Department of Operative Dentistry and Periodontology,  
University of Tübingen Center of Dentistry Oral Medicine Maxillofacial Surgery,  
Tübingen, Germany*

### **Background**

The widespread use of systemic antibiotics in medicine and dentistry becomes an increasingly serious problem by eliciting drug resistance and undesirable side effects. In dentistry, there are several antiseptic mouthrinses for topical use available, showing different mechanisms of action to inhibit dental pathogens, for instance those associated with periodontitis and peri-implantitis.

### **Objectives**

Aim of the study was to investigate the antimicrobial efficacy of eight antiseptic mouthrinses containing six different types of active ingredients for the use on planktonic periodontitis-associated pathogens.

### **Methods**

Six representative periodontitis/peri-implantitis associated pathogens were grown anaerobically for 24h. After suspension, the six-strain-cocktail was exposed to the following agents for 30 seconds:

1. NaCl (saline as negative control), 2. CHX (0.2%) (chlorhexidine), 3. CHX (0.06%), 4. CHX+CPC (CHX 0.05% + cetylpyridinium chloride 0.05%), 5. PH (polyhexanide 0.04%), 6. PH 0.1%+betaine, 7. Oct (octenidine dihydrochloride + phenoxyethanol), 8. FF (amine fluoride/stannous fluoride), and 9. EO (mouthwash containing essential oils). Microbial viability was monitored by both colony growth (CFU/ml) and fluorescence-based vitality. Six independent series of experiments were conducted. Statistical analysis of data was performed using mean-based 95% confidence intervals, ANOVA analysis and the Tukey test.

### **Conclusions**

The strongest antibacterial CFU reduction of 8.75 log<sub>10</sub> units could be shown for the agents 2, 4 and 7. Furthermore, strong colony growth reduction of 7.25-6.36 was

caused by the agents 6, 8 and 9. Moderate to low antibacterial activity was induced by the exposure to agents 3 and 5 ( $\log_{10}$  CFU reduction of 3.80-2.25). Bacterial vitality was strongly reduced by all antiseptic agents.

#### **CHARACTERIZATION OF ESBL PRODUCING ESCHERICHIA COLI IN NORTHERN THAILAND**

M. Deeudom<sup>1</sup>, P. Tuntrakul<sup>1</sup>, P. Tharavichitkul<sup>1</sup>, J. Wicheano<sup>2</sup>, K. Duangsonk<sup>1</sup>, B. Khantawa<sup>3</sup>

<sup>1</sup>Department of Microbiology, Faculty of Medicine Chiang Mai University, Chiang Mai, Thailand

<sup>2</sup>Department of Medical Technology, Faculty of Associated Medical Sciences Chiang Mai University, Chiang Mai, Thailand

<sup>3</sup>Microbiology Laboratory Diagnostic Laboratory, Maharaj Nakorn Chiang Mai Hospital, Chiang Mai, Thailand

#### **Background**

The prevalence of extended spectrum beta-lactamase (ESBL) producing *Escherichia coli* has reached to 41-44 % of total *E. coli* infections in a tertiary center Maharaj Nakorn Chiang Mai Hospital (MNCMH) during past six years. To date, there is no report on distribution of ESBL genes and levels of resistance to third generation cephalosporins among *E. coli* clinical isolates from any hospital in Northern Thailand.

#### **Objectives**

To study the correlation between distribution of ESBL genes and levels of resistance to cefotaxime and ceftazidime.

#### **Methods**

435 *E. coli* strains collected from MNCMH during April to May, 2010 were screened for production of ESBL and AmpC BL. MICs of cefotaxime and ceftazidime were determined in ESBL producers. ESBL and AmpC BL genes were detected using multiplex PCR and nucleotide sequencing.

#### **Conclusions**

Of 182 ESBL producers, 25 strains also produced AmpC BL. The MIC<sub>50</sub>/MIC<sub>90</sub> of CTX and CAZ were 128/512 and 16/128 µg/ml, respectively. ESBL genes detected were *bla*<sub>TEM</sub> (82.9%), *bla*<sub>CTX-M</sub> (80.7% ; *bla*<sub>CTX-M-group 1</sub> and *bla*<sub>CTX-M-group 9</sub>), and *bla*<sub>SHV</sub> (11%). *bla*<sub>CTX-M-15</sub> and *bla*<sub>CTX-M-55</sub> predominated among *bla*<sub>CTX-M-group 1</sub> whereas *bla*<sub>CMY2</sub> among AmpC BL producers. Most strains carried multiple beta-lactamase genes. The predominant genotypes were *bla*<sub>TEM</sub> + *bla*<sub>CTX-M-group 1</sub> and *bla*<sub>TEM</sub> + *bla*<sub>CTX-M-group 9</sub>. Levels of resistance to cefotaxime and ceftazidime depended on type of beta-lactamase gene, not the accumulating number of genes. The presence of *bla*<sub>CTX-M-group 1</sub> was associated with resistance to both cefotaxime and ceftazidime. However, the

presence of *bla*<sub>CTX-M-group 9</sub> was associated with more resistance to cefotaxime and more sensitivity to ceftazidime.

### **Antimicrobial resistance**

## **FITNESS STUDIES OF PZA RESISTANT MYCOBACTERIUM TUBERCULOSIS STRAINS**

A. den Hertog<sup>1</sup>, S. Menting<sup>1</sup>, S. Sengstake<sup>1</sup>, R. Anthony<sup>1</sup>

<sup>1</sup>KIT Biomedical Research, Royal Tropical Institute (KIT), Amsterdam, Netherlands

### **Background**

Pyrazinamide (PZA) is the only first line tuberculosis (TB) drugs to have significant activity against dormant TB. PZA resistance in *Mycobacterium tuberculosis* is most frequently conferred by mutations in pyrazinamidase (PZase), the enzyme required to activate PZA. These resistance mutations are sometimes stated to have no fitness cost, but in fact laboratory evidence seems absent for either a fitness cost or lack thereof.

PZase is non-essential during active growth, but its transcription is upregulated during oxygen and nutrient limitation. The role of PZase in NAD salvaging supports requirement of PZase during dormancy, and thus PZA resistant strains without functional PZase may have a measurably decreased fitness. Epidemiological data showing only limited spread of PZA resistant strains also suggests a lower fitness.

### **Objectives**

Objective of this study is to determine the fitness of PZA resistant TB strains in a dormancy model.

### **Methods**

Isogenic PZA susceptible and resistant strains of *M. tuberculosis* are cultured in the Wayne hypoxic dormancy model in non-selective media, and viability investigated over time.

### **Conclusions**

In the first 2 months of dormancy model culture, proportions of both the PZA resistant and susceptible bacteria remained viable as determined by live/dead staining and culture. Auramine/NileRed stainings demonstrate decreasing proportions of acid-fast bacilli and increasing proportions of lipid inclusion over time in susceptible and resistant strains.

No measurable difference in fitness was observed between the strains during the first two months, viability will be further assessed for additional time points to assess the long term survival of these dormant cultures.

**Antimicrobial resistance**

## **ANTIBACTERIAL ACTIVITY AND MECHANISM OF ACTION OF EUGENOL AGAINST MULTI-DRUG RESISTANT PATHOGENIC BACTERIA**

J. Ebenezer<sup>1</sup>, R. Lawrence<sup>1</sup>

<sup>1</sup>*Microbiology and Fermentation Technology,*

*Sam Higginbottom Institute of Agriculture Technology & Sciences, Allahabad, India*

### **Background**

Antibiotic resistance in clinical isolates is an increasing life-threatening global threat. Newer approaches and drugs are required to control these organisms in the current scenario. The *in vitro* antibacterial activity and mechanism of eugenol, a natural phenylpropene was studied against multi-drug resistant clinical isolates.

### **Objectives**

The present study was conducted to evaluate the antibacterial property of eugenol against multi-drug resistant clinical bacterial pathogens. Further, minimum inhibitory concentration and bactericidal concentration of eugenol along with mechanistic action was determined.

### **Methods**

Antimicrobial minimum inhibitory concentration and bactericidal concentration experiments with eugenol was measured against a range of Gram positive and Gram negative bacteria isolated from clinical specimens using Resazurin micro-titre assay. Analysis of killing kinetics of eugenol was performed against two strains (*Escherichia coli* and *Staphylococcus aureus*). The effect of divalent salts on the activity of eugenol was determined. Bioluminescence method was used to determine the effect of eugenol on the intracellular pool of bacterial ATP. Membrane depolarization studies were conducted to study the cell wall permeabilization. The morphological changes in bacterial membrane due to the activity of eugenol were investigated using scanning and transmission electron microscopy studies.

### **Conclusions**

The results provide additional experimental data that are consistent with the hypothesis that eugenol represents a new class of antibacterial agents for treating multi-drug resistant pathogenic bacteria and acts *via* different mechanism from conventional antibiotics. The results suggest that antibacterial activity is due to

interaction of eugenol on bacterial cell membrane. The results also revealed that cell wall and membrane of treated bacteria were significantly damaged.

#### **PREVALENCE AND CHARACTERIZATION OF BLA CTX-M, BLA TEM AND BLA SHV FROM ESBL PRODUCING ORGANISMS FROM HOSPITALS IN LAGOS, NIGERIA.**

T. Egwuatu<sup>1</sup>, F. Ogunsola<sup>1</sup>, F. Nwokorie<sup>2</sup>, E. Ugoji<sup>3</sup>, C. Edokwe<sup>3</sup>, B. Awobamise<sup>3</sup>, V. Abudah<sup>3</sup>, F. Akanbi<sup>3</sup>, A. Akinyelure<sup>3</sup>

<sup>1</sup>Microbiology,

College of Medicine University of Lagos/Lagos University Teaching Hospital Lagos, Lagos, Nigeria

<sup>2</sup>Molecular Biotechnology, Nigerian Institute of Medical Research Yaba Lagos, Lagos, Nigeria

<sup>3</sup>Microbiology, University of Lagos, Lagos, Nigeria

### **Background**

The increasingly prevalent of Extended-Spectrum  $\beta$ -Lactamase (ESBL) among clinical isolates are becoming wide spread globally. Most reports on ESBL from Nigeria have always rested on their phenotypic statues with just a few with information on their molecular types.

### **Objectives**

We therefore set out to to characterize the Beta-lactamases in multidrug resistant clinical isolates of *Enterobacteriaceae* by molecular techniques.

### **Methods**

One hundred and sixteen non-duplicate clinical isolates from 3 hospitals including a Teaching hospital were screened for ESBL production, 42 of them were phenotypically confirmed as ESBL producers. Molecular analysis by PCR and Pulsed Gel Electrophoresis used in the detection of TEM, SHV and CTX-M ESBL genes revealed 100% prevalence for CTX-M, 57.1% TEM and 64.3% SHV. *Klebsiella pneumoniae* and *E. coli* respectively had the most frequency of ESBL genes with *Serratia rubidae* with the lowest frequency of occurrence. All ESBL producers showed resistance to at least 2 or more classes of antibiotics and varied resistance to meropenem (carbapenem).

### **Conclusions**

Despite several researches and reports on ESBL in Nigeria, there is still no known awareness for its routine detection in the private and public hospital laboratories. It

seems as though the fact is simply ignored. This study has brought to light the extent of the spread of these organisms in Lagos and call for stringent policies to be put in place to reduce antibiotic misuse and abuse.

## **FEMS-1854**

### **Antimicrobial resistance**

#### **RETROSPECTIVE DETECTION OF THE HIDDEN SPREAD OF OXA-48-PRODUCING KLEBSIELLA PNEUMONIAE IN A FRENCH TEACHING HOSPITAL**

H. Pailhoriès<sup>1</sup>, C. Lemarie<sup>1</sup>, M. Kempf<sup>1</sup>, C. Mahaza<sup>1</sup>, M.L. Joly-Guillou<sup>1</sup>, M. Eveillard<sup>1</sup>

<sup>1</sup>Microbiology, Angers teaching hospital, Angers, France

### **Background**

In our hospital, an outbreak of OXA-48-producing *Klebsiella pneumoniae* (OXA48KP) was identified in the end of 2013. For these strains, the Vitek2 System (V2S) categorised the ertapenem intermediate or resistant (I/R), whereas it could have been categorised susceptible by E-test (E-test is systematically performed if ertapenem is categorised I/R with the V2S). Before the outbreak, no screening for carbapenemases was performed for isolates identified as susceptible to ertapenem by E-tests.

### **Objectives**

The objective of this study was to determine the presence of OXA48KP before the moment of the outbreak detection.

### **Methods**

From January 2010 to the end of 2013, all *K. pneumoniae* isolates for which ertapenem was tested by E-test were selected. These isolates were then tested for the presence of carbapenemase with the KPC, MBL and OXA-48 confirm Kit (ROSCO Diagnostica, Taastrup, Denmark). The isolates with an inhibition diameter around temocillin <12 mm were then tested for OXA-48 by PCR and compared by PFGE.

### **Conclusions**

Among the 21 isolates included, 3 were identified as OXA48KP. PFGE analysis demonstrated that two of them were closely-related to the outbreak isolates and one was not related. They had been initially considered susceptible by E-test (MIC from 0.25 to 0.5 mg/L) and had been identified from samples collected within the 6 months preceding outbreak detection. Therefore, there was probably a hidden spread of the outbreak before triggering the alert at the end of 2013. In addition, these results show the high sensitivity of the V2S for carbapenemase detection.

## **FEMS-1010**

### **Antimicrobial resistance**

#### **CHARACTERIZATION OF THE RESISTANCE MECHANISM TO DITYROMYCIN OF THE STREPTOMYCES PRODUCER STRAIN.**

A. Fabbretti<sup>1</sup>, A. La Teana<sup>2</sup>, A.M. Giuliadori<sup>1</sup>, R. Spurio<sup>1</sup>

<sup>1</sup>Biosciences and Veterinary Medicine, University of Camerino, Camerino, Italy

<sup>2</sup>Life and Environmental Sciences, Università Politecnica delle Marche, Ancona, Italy

#### **Background**

Dityromycin is a peptide antibiotic produced by *Streptomyces* sp. strain AM-2504<sup>1</sup> with the structure highly related to that of GE82832<sup>2</sup>. The crystal structure of Dityromycin - 70S ribosome complex revealed that the binding involves conserved amino acid residues of ribosomal protein S12<sup>3</sup>. Dityromycin inhibits EF-G activity by disrupting critical contacts between EF-G and S12 that are required to stabilize the post-translocational conformation of EF-G, thereby preventing the ribosome-EF-G complex from entering a productive arrangement for translocation<sup>3</sup>.

#### **Objectives**

The aim of this work was to identify the mechanism of resistance to Dityromycin of the producer strain *Streptomyces* sp. AM-2504.

#### **Methods**

Cell-free *in vitro* translation tests, genome walking and direct sequencing of the *rpsL* gene were used to characterize the mechanism of resistance of this antibiotic.

#### **Conclusions**

The results obtained in this work indicate that the resistance of the producer strain to Dityromycin is due to a modification of its ribosomes. In particular, three amino acids changing mutations were found in an highly conserved region of the protein S12 corresponding to the binding site of the antibiotic. These mutations cause a substantial loss of affinity of Dityromycin for the 30S ribosomal subunit thus conferring resistance to the producer strain. Results of this study contribute to the knowledge of the molecular determinants developed and successfully implemented by the antibiotic production/resistance machinery.

**HAS THE USE OF FLUOROQUINOLONES CONTRIBUTED TO THE WIDESPREAD DISSEMINATION OF METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS AND EXTENDED-SPECTRUM B-LACTAMASE-PRODUCING KLEBSIELLA PNEUMONIAE IN THE HEALTHCARE SETTING?**

M. Fuzi<sup>1</sup>

<sup>1</sup>*Institute for Medical Microbiology, Semmelweis University, Budapest, Hungary*

**Background**

We recently demonstrated that fitness cost associated with resistance to fluoroquinolones is diverse across clones of both methicillin-resistant *Staphylococcus aureus* (MRSA) and extended-spectrum  $\beta$ -lactamase (ESBL)-producing *Klebsiella pneumoniae* in adult hospital wards. We observed that major clone MRSA and ESBL-producing *K. pneumoniae* strains with high-level resistance to fluoroquinolones retain their fitness while the vitality of other *S. aureus* and *K. pneumoniae* isolates become more compromised during the development of resistance to these antibiotics. Our observation with MRSA was subsequently confirmed by British scientists. In addition our findings may account for the replacement of SHV type ESBL genes by CTX-M-15 in *K. pneumoniae* reported during the last decade.

**Objectives**

Investigation of whether or not this mechanism - the selection of the major clones of MRSA and ESBL--producing *K. pneumoniae* by fluoroquinolones - could have contributed to the widespread dissemination of both pathogens.

**Methods**

Review of related literature.

**Conclusions**

An overwhelming part of the related literature supports the assumption.

Our findings suggest that a more judicious use of fluoroquinolones could significantly decrease the rates for both MRSA and ESBL-producing *K. pneumoniae* in the adult healthcare setting.

### Antimicrobial resistance

#### WHICH ANTIBIOTIC SHOULD BE PRESCRIBED FOR ERADICATION OF KLEBSIELLA PNEUMONIAE NOSOCOMIAL INFECTIONS IN ILAM HOSPITALS? AMOXICILLIN OR AMIKACIN?

S. Ghafourian<sup>1</sup>, F. Valian<sup>2</sup>, H. Valadbeigi<sup>2</sup>, N. Valizadeh<sup>2</sup>, N. Sadeghifard<sup>2</sup>, M. Taherikalan<sup>2</sup>

<sup>1</sup>Medical Microbiology and Parasitology, university putra malaysia, putra, Malaysia

<sup>2</sup>Clinical Microbiology Research Center, Ilam University of Medical Sciences, Ilam, Iran

#### Background

The relax prescription of antibiotics in Iran made an evolution in bacterial populations. Antibiotic resistance strains specially noscomial strains cause too issues for treatment of bacteria responsible for nosocomial infections. *Klebsiella pneumoniae* is also known as a hard to treat bacterium in Ilam hospitals and the rate of resistance is different from antibiotic to antibiotic.

#### Objectives

Therefore, the current study aims to evaluate the prevalence of different antibiotics for treatment of *K. pneumoniae* clinical isolates and open new insight for antibiotic suspension or prescription.

#### Methods

48 *K. pneumoniae* clinical isolates were identified as standard procedures during March 2013 to March 2014 in Ilam hospitals. The isolates were collected from in and out patients with urinary tract infections. The isolates were then subjected to antibiotic susceptibility testing via disk diffusion method as CLSI guideline. The antibiotic resistance pattern and significant difference among *K. pneumoniae* and different antibiotics were calculated by spss 16 via chi-square.

#### Conclusions

The antibiotic susceptibility pattern demonstrated 39.6%, 27.1%, 27.1%, 16.7%, 39.6%, 37.5%, 10.4%, 54.2%, 8.3%, 75%, 27.1%, 50%, and 97.9% resistance to gentamicin, ciprofloxacin, ceftazidime, piperacillin, aztreonam, chloramphenicol, nitrofurantoin, cephalotin, amikacin, cefuroxime, tetracycline, cephazolin, and amoxicillin, respectively. The findings demonstrated high resistance in *K. pneumoniae* clinical strains. This study recommended the new policy with prescription of amikacin and non-prescription of amoxicillin as a dominant susceptible and resistance antibiotic in *K. pneumoniae* clinical isolates.

## ADES MUTATIONS IN MDR-ACINETOBACTER BAUMANNII CLINICAL ISOLATES WITH TIGECYCLINE REDUCED SUSCEPTIBILITY FROM CAIRO, EGYPT.

D. Ghaith<sup>1</sup>, R. Hassan<sup>1</sup>, A. Mukhtar<sup>2</sup>, A. Hasanin<sup>2</sup>

<sup>1</sup>Clinical and Chemical PathologyCairo University, Faculty of Medicine, Cairo, Egypt

<sup>2</sup>Anesthesia Cairo University, Faculty of Medicine, Cairo, Egypt

### Background

Infections caused by multidrug resistant (MDR) *Acinetobacter baumannii* (*A. baumannii*) especially in intensive care units have limited therapeutic options, one of them is Tigecycline. Overexpression of the adeABC efflux pump may be caused either by the IS*Aba*-1 insertion or by specific point mutations in *adeR* and *adeS*, therefore plays a major role in conferring MDR- *A. baumannii*.

### Objectives

We aimed in our study to monitor the TGC susceptibility and to study the role of IS*Aba*-1 and the *adeS* regulator within the AdeABC efflux pump among MDR- *A. baumannii* clinical isolates.

### Methods

Over 18 months from April 2012 to September 2013, 63 MDR-*A. baumannii* identified by detection of OXA-51 like gene were isolated from ICU patients. TGC MIC was determined by E test and confirmed by broth microdilution. PCR analysis of *adeR*, *adeS*, *adeB*, and IS*Aba*1 genes were done with further sequencing of *adeS* gene.

### Conclusions

Reduced susceptibility to TGC (MIC: 3-4ml/L) was noticed in 6/63 (9.5 %) MDR- *A.*

*baumannii* isolates, insertion sequence IS*Aba*-1 was detected in 3 isolates , two of them showed amino acid substitutions in the *adeS* operon by sequencing. IS*Aba*-1 may play a role in conferring reduced TGC susceptibility in MDR- *A. baumannii* in association with amino acids mutations in the *adeS* gene

**MOLECULAR CHARACTERIZATION AND EPIDEMIOLOGY OF CEFOTAXIME RESISTANCE AMONG ENTEROBACTERIACEAE LACKING INDUCIBLE CHROMOSOMAL AMPC GENES FROM HOSPITALIZED AND NON-HOSPITALIZED PATIENTS IN ALGERIA**

A. GHAROUT-SAIT<sup>1</sup>, A. TOUATI<sup>1</sup>, T. GUILLARD<sup>2</sup>, L. BRASME<sup>2</sup>, C. DE CHAMPS<sup>2</sup>

<sup>1</sup>microbiology, A. Mira University, Bejaia, Algeria

<sup>2</sup>Laboratoire de Bactériologie–Virologie-Hygiène Hospitalière, CHU DE REIMS, Reims, France

**Background**

Plasmid-mediated AmpC  $\beta$ -lactamases have emerged and are being reported worldwide with varying prevalence rates. In Algeria, only few reports on plasmid-encoded AmpC in *Enterobacteriaceae* strains recovered from hospital settings were published.

**Objectives**

The aim of this study was to investigate the prevalence and molecular epidemiology of cefotaxime resistance among *Enterobacteriaceae* isolates recovered from hospitalized and non-hospitalized patients in Bejaia locality (Algeria). The association of pAmpC with ESBL and plasmid-mediated quinolone resistance determinant was also studied.

**Methods**

In this study, 922 consecutive non-duplicate clinical isolates of *Enterobacteriaceae* obtained from hospitalized and non-hospitalized patients at Bejaia, Algeria, were analyzed for AmpC type  $\beta$ -lactamases production. The *ampC* genes and their genetic environment were characterized using PCR and sequencing. Plasmid incompatibility groups were determined using PCR-based replicon typing. Phylogenetic grouping and Multilocus sequence typing (MLST) were determined for molecular typing of the plasmid encoded AmpC (pAmpC)-producing isolates.

**Conclusions**

Of the isolates, 15 were identified as AmpC producers including 14 CMY-4-producing isolates and one DHA-1-producing *K. pneumoniae*. All AmpC-producing isolates co-expressed the broad-spectrum TEM-1  $\beta$ -lactamase and three of them co-produced CTX-M and/or SHV-12 ESBL. Phylogenetic grouping and virulence genotyping of the

*E. coli* isolates revealed that most of them belonged to groups D and B1. MLST analysis of *K. pneumoniae* isolates identified four different STs with two new sequences: ST1617 and ST1618. Plasmid replicon typing indicates that *bla*<sub>CMY-4</sub> gene was located on broad host range A/C plasmid, while LVPK replicon was associated with *bla*<sub>DHA-1</sub>. All isolates carrying *bla*<sub>CMY-4</sub>, displayed the transposon-like structures ISEcp1/ΔISEcp1-*bla*<sub>CMY</sub>-*blc*-*sugE*.

#### ENTEROCOCCAL COLONIZATION AND INFECTION IN LUNG TRANSPLANT PATIENTS WITH VENTILATOR ASSOCIATED PNEUMONIA: QUANTITATIVE CULTURE, DRUG SUSCEPTIBILITY TESTING AND PFGE PROFILING

A. Ghodousi<sup>1</sup>, M. Omrani<sup>1</sup>, B. Nomanpour<sup>1</sup>, M.M. Feizabadi<sup>1</sup>

<sup>1</sup>Clinical Microbiology, Tehran University of Medical Sciences, Tehran, Iran

#### Background

Vancomycin-resistant enterococci (VRE) are among the most common antibiotic-resistant nosocomial pathogens in health care in general and in intensive care units (ICUs), in particular.

#### Objectives

The main purpose of this study is to distinguish between lower respiratory tract (LRT) colonization and infection due to enterococci using semi-quantitative cultures.

#### Methods

Sixty-eight lower respiratory tract (LRT) specimens were collected from consecutive adult patients who underwent Lung transplantation and were developed ventilator associated pneumonia (VAP) from three teaching hospitals in Tehran, Iran, during December 2009 – September 2012. A semi-quantitative threshold of  $>10^4$  cfu/ml was considered to be diagnostic for Enterococcal-VAP. Antibacterial resistance patterns of isolates to 13 antimicrobial agents were analyzed according to EUCAST. Pulsed Field Gel Electrophoresis (PFGE) was performed as described previously (Feizabadi, M.M. *et al.* J Microbiol Methods 2011; 84:144 –146).

#### Conclusions

Twenty-three and four isolates of *E. faecalis* and *E. faecium* showed  $>10^4$  cfu/ml which corresponds to infection. Linezolid, teicoplanin and vancomycin were found to be the most effective drugs.

The results of MIC for vancomycin and teicoplanin are shown in the table. Seven and two different DNA banding patterns were identified among *E. faecalis* and *E. faecium* isolates, respectively.

Infection of LRT with enterococci seems to become serious and needs to be reconsidered as a real problem rather than colonization. In such cases clones of VRE is associated with high mortality.

	Number of isolates	MIC of vancomycin 64≥mg/mL	MIC of vancomycin 256≥mg/mL	MIC of teicoplanin

				256≥mg/mL
<i>E. faecalis</i>	26	7	5	4
<i>E. faecium</i>	4	4	4	4

#### **EVALUATION OF MULTIPLEX TANDEM REAL TIME PCR KIT FOR RAPID IDENTIFICATION OF GRAM-POSITIVE COCCI FROM BLOOD CULTURES AND DETECTION OF MECA AND VAN GENES**

B. Gülhan<sup>1</sup>, A. Çıkman<sup>1</sup>, M. Aydın<sup>1</sup>, M. Hasbek<sup>2</sup>, T. Özekinci<sup>3</sup>

<sup>1</sup>Medical Microbiology, Erzincan University Faculty of Medicine, Erzincan, Turkey

<sup>2</sup>Medical Microbiology, Sivas Numune Training Hospital, Sivas, Turkey

<sup>3</sup>Medical Microbiology, Dicle University Faculty of Medicine, Diyarbakır, Turkey

#### **Background**

Currently available automated blood culture systems have significantly reduced bacteria detection time. However; so as to get optimum treatment, more rapid identification systems are required.

#### **Objectives**

Gram Positive 12 Kit (Aus Diagnostics, Australia) makes it possible to identify common Gram positive bacteria (*Staphylococcus* spp., *Streptococcus* spp., *Enterococcus* spp.) and to detect common antibiotic resistant genes (*mecA*, *vanA*, *vanB*). The aim of this study was to rapidly identify and to assess the performance of this test for sepsis agent Gram positive bacteria and resistance genes.

#### **Methods**

54 patients having positive blood cultures and Gram-positive cocci in Gram staining were included in the study. After the DNA isolation, identification and resistance genes were determined by using Easy Plex pipetting robot, and then Rotor GeneQ (Qiagen, Switzerland) real-time PCR device for pre- PCR and PCR set up phases with this multiplex tandem real time PCR kit. Results were compared to the results obtained from PHOENIX (BectonDickinson, USA) and Vitek 2 Compact (bioMérieux, France) automated systems.

#### **Conclusions**

42 results were completely as same as the results from PHOENIX and Vitek 2 Compact automated systems. Additionally; 12 polymicrobial infections which could not be detected by automated systems were successfully detected.

In conclusion; the kit which was evaluated proved to be both rapid (approximately 2,5 hours) and reliable in determining common Gram positive sepsis pathogens and resistance genes. According to our results, it could be concluded that the test could easily be used in patients who are suspected of sepsis in routine diagnosis.

## **FEMS-2734**

### **Antimicrobial resistance**

#### **RAPID IDENTIFICATION OF GRAM-NEGATIVE PATHOGENS FROM BLOOD CULTURES AND DETECTION OF RESISTANCE GENES**

*B. Gülhan<sup>1</sup>, A. Çıkman<sup>1</sup>, M. Aydın<sup>1</sup>, M. Hasbek<sup>2</sup>, T. Özekinci<sup>3</sup>*

<sup>1</sup>*Medical Microbiology, Erzincan University Faculty of Medicine, Erzincan, Turkey*

<sup>2</sup>*Medical Microbiology, Sivas Numune Training Hospital, Sivas, Turkey*

<sup>3</sup>*Medical Microbiology, Dicle University Faculty of Medicine, Diyarbakır, Turkey*

#### **Background**

Currently available automated blood culture systems have significantly reduced bacteria detection time. However; so as to get optimum treatment, more rapid identification systems are required.

#### **Objectives**

Gram negative 12 Kit (Aus Diagnostics, Australia) makes it possible to identify common Gram negative bacteria (Enterobacteriaceae, Pseudomonas spp., Pseudomonas aeruginosa, Escherichia coli, Klebsiella pneumoniae) and to detect common antibiotic resistant genes. The aim of this study was to rapidly identify and to assess the performance of this test for sepsis agent Gram negative bacteria and resistance genes.

#### **Methods**

78 patients having positive blood cultures and Gram-negative bacilli in Gram staining were included in the study. After the DNA isolation, identification and resistance genes were determined by using Easy Plex pipetting robot, and then Rotor GeneQ (Qiagen, Switzerland) real-time PCR device for pre- PCR and PCR set up phases with this multiplex tandem real time PCR kit. Results were compared to the results obtained from PHOENIX (Becton Dickinson, USA) and Vitek 2 Compact (bioMérieux, France) automated systems.

#### **Conclusions**

All of the pathogens were successfully identified by using this test. Oxa-23 gene, aadA1 gene, pan-vim genes, aadB gene were found in 5, 15, 3, 2 samples; respectively.

In conclusion; the kit which was evaluated proved to be both rapid (approximately 2,5 hours) and reliable in determining common Gram negative sepsis pathogens and resistance genes. According to our results, it could be concluded that the test could easily be used in patients who are suspected of sepsis in routine diagnosis.

<sup>3</sup>Department of Medical Mycology and Parasitology,  
Infectious and Tropical Medicine Research Center Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran

### **Background**

Dermatophytosis is one of the most common fungal infections in humans. In vitro antifungal susceptibility testing is considered as a powerful method to seek the drug of choice among the available anti-dermatophyte agents as well as to optimize the therapy against dermatophytosis.

### **Objectives**

we aimed the antifungal susceptibility of isolated dermatophytes from Iran against some common antifungal agents for the treatment of dermatophytosis.

### **Methods**

The isolates were identified by traditional macroscopic and microscopic findings as well as PCR-RFLP. A total of 316 clinical isolates from patients with dermatophytosis including *Trichophyton interdigitale* ( $n = 156$ ), *T. rubrum* ( $n = 60$ ), *Epidermophyton floccosum* ( $n = 42$ ), *Microsporum canis* ( $n = 29$ ), *Arthroderma benhamiae* ( $n = 17$ ) and *T. tonsurans* ( $n = 12$ ) were tested for antifungal activities against terbinafine, itraconazole, griseofulvin and fluconazole by broth microdilution technique according to the recommendation of the Clinical and Laboratory Standards Institute (CLSI) M38-A2 document.

### **Conclusions**

The MIC ranges were as follows: terbinafine, 0.002 to 0.25 µg/mL; itraconazole, 0.004 to 0.5 µg/mL; griseofulvin, 0.125 to 8 µg/mL and fluconazole 4 to 128 µg/mL. Terbinafine and fluconazole had the highest and lowest activity against dermatophytes isolates, respectively. *Epidermophyton floccosum*, *Microsporum canis* and *Trichophyton tonsurans* were the most susceptible species to terbinafine. Terbinafine had the lowest activity against *Arthroderma benhamiae*. *E. floccosum* showed the highest susceptibility to itraconazole. *T. rubrum* had the lowest

susceptibility to itraconazole. According to our data we profoundly propose to physicians to exclude fluconazole for treatment of dermatophytosis.

#### SRL PATHOGENICITY ISLAND IS ASSOCIATED TO MULTIDRUG RESISTANCE IN SHIGELLA STRAINS ISOLATED FROM CHILE

T. Henríquez<sup>1</sup>, C. García<sup>1</sup>, P. Díaz<sup>1</sup>, A. Miranda<sup>1</sup>, B. Ávila<sup>1</sup>, M. Bugueño<sup>1</sup>, R. Astorga<sup>1</sup>, J. Silva<sup>2</sup>, R. Camponovo<sup>3</sup>, G. Hermosilla<sup>1</sup>, M.T. Ulloa<sup>1</sup>, C.S. Toro<sup>1</sup>

<sup>1</sup>Programa de Microbiología y Micología,  
Instituto de Ciencias Biomédicas (ICBM) Facultad de Medicina Universidad de Chile,  
Santiago, Chile

<sup>2</sup>Departamento de Tecnología Médica,  
Facultad de Ciencias de la Salud Universidad de Antofagasta, Antofagasta, Chile

<sup>3</sup>Laboratorio de Microbiología, Integramédica, Santiago, Chile

#### Background

*Shigella* spp., the etiologic agent of shigellosis, becomes a major problem of public health due to the increasing multidrug-resistance to antibiotic (MDR). In this context, the *Shigella* resistance locus (SRL) pathogenicity island (PAI) mediates resistance to streptomycin, ampicillin, chloramphenicol, and tetracycline, contributing to MDR phenotype.

#### Objectives

To characterize the presence and genetic organization of SRL PAI in Chilean *Shigella* spp. strains.

#### Methods

We selected 135 strains of *S. sonnei* and *S. flexneri*. We determined susceptibility to antibiotics using agar diffusion method, and detected seven specific SRL markers (*orf9*, *orf58*, *oxa-1*, *tet*, *cat*, and its sites of insertion in the chromosome) by PCR. Also, we assessed the presence of integrons. Then, we selected representative strains and analyzed them by Tilling-PCR for the complete island organization.

#### Conclusions

Our results indicate that most of these strains are MDR strains to  $\geq 3$  antibiotic class ( $> 78\%$ ), all of them had the SRL PAI. Besides, a high rate of the isolated was positive for class 1 integron (80%), which is concordant with the presence of the SRL PAI and negative for integron class 2.

Meanwhile, tilling-PCR for SRL PAI and sequencing indicated that in the 5' end there are four variants with different insertions. Only one insertion was found in the 3' end, compared to the reference strain, YSH6000. In conclusion, this work points out the diversity of variants of the SRL PAI in the Chilean *Shigella* spp strains, and its huge contribution to the MDR phenotype.

## **MOLECULAR EPIDEMIOLOGY OF PLASMIDS MEDIATING OXA-48 CARBAPENEMASE DISSEMINATION**

L. Hidalgo<sup>1</sup>, M. de Been<sup>1</sup>, M.R.C. Rogers<sup>1</sup>, J. Scharringa<sup>1</sup>, A. van der Zee<sup>2</sup>,  
M.J.M. Bonten<sup>1</sup>, A.C. Fluit<sup>1</sup>

<sup>1</sup>Medical Microbiology, University Medical Center Utrecht, Utrecht, Netherlands

<sup>2</sup>Molecular Diagnostics Unit, Maasstad Laboratory, Rotterdam, Netherlands

### **Background**

OXA-48 carbapenemase has become of major significance as a result of the progressive identification of nosocomial *Klebsiella pneumoniae* producing this enzyme. It has been reported mostly in Mediterranean countries, although it is increasingly detected in Northern Europe. The recent spread of a clonal OXA-48-producing *K. pneumoniae* as well as other *Enterobacteriaceae* in a Dutch hospital has resulted in one of the largest OXA-48 related outbreaks in Europe so far<sup>1</sup>.

### **Objectives**

The OXA-48 gene has been associated with 60- to 70-kb plasmids. Our aim was to perform a large-scale study using a next-generation sequencing approach to better understand the molecular epidemiology of plasmids carrying *bla*<sub>OXA-48</sub>.

### **Methods**

A total of 89 OXA-48-producing bacteria isolated from the Dutch hospital outbreak<sup>1</sup> as well as from other locations in the Netherlands and endemic countries were selected. Plasmids were sequenced using the Illumina Miseq platform, and read sets were assembled *de novo* using Spades. Plasmid sequences were annotated with Prokka, and Samtools was used to identify SNPs and INDELs.

### **Conclusions**

Sequencing data revealed 3 plasmid clusters of ca. 62kb, 30kb, and 13kb. All the plasmids shared an identical common region including the Tn 1999 where *bla*<sub>OXA-48</sub> is embedded, suggesting the presence of a highly modular plasmid ancestor. No link was found between plasmid clusters and origin of the strains. However, our results show several cases of plasmid transfer between bacterial species in the same patient over time, which represents a major driver for plasmid maintenance and spread despite control of the outbreak.

## **ANTIMICROBIAL ACTIVITY OF CHLORELLA VULGARIS EXTRACTS AGAINST FOODBORNE PATHOGENIC BACTERIA**

T. ICA<sup>1</sup>, F. Colak<sup>1</sup>

<sup>1</sup>Faculty of Art and Science Department of Biology, Dumlupinar University, Kutahya, Turkey

### **Background**

Foodborne bacterial pathogens cause a major public health problem. In the last few decades, increased resistance of bacterial strains to antibiotics lead to search alternative effective compound against food borne pathogens.

### **Objectives**

In this study was aimed at evaluating the antimicrobial activity of different extracts from *Chlorella vulgaris* on food borne pathogens. Systematic screening of them may result in the discovery of novel effective compounds.

### **Methods**

*Chlorella vulgaris* (UTEX 2714) was grown in axenic cultures of 3N-Basal Bold Medium. Chloroform, methanol, ethanol, diethyl ether, acetone and ethyl acetate extracts were extracted directly from 5 mg dried *C.vulgaris* biomass. *Staphylococcus aureus*, *Listeria grayii*, *L.monocytogenes*, *L. innocua*, *Enterococcus faecalis* and *E. faecium* strains was isolated from cheese, minced meat and poultry product and identified by molecular techniques. Disc diffusion methods were used to determine the antimicrobial activity of *C. vulgaris* extracts on the foodborne pathogens. Results compared with streptomycin and amikacin results which was used as positive control.

### **Conclusions**

*C.vulgaris* extracts possessed potential antibacterial activities against foodborne gram positive bacterial strains with inhibition zones ranged for *S.aureus*, *E. faecalis* and *E.faecium* 7-14 mm, *L.monocytogenes* 7-12 mm, *L.grayi* 7-14 mm, *L.innocua* 7-15 mm, Thus, it could be suggested that the *C.vulgaris* is useful biosystem for production of new antimicrobial compound that has an effect against gram positive bacteria.

**Antimicrobial resistance**

## **THE GENOMES OF CARBAPENEM-RESISTANT PATHOGENS OF FIVE DIFFERENT SPECIES ISOLATED AT A SWEDISH HOSPITAL**

A. Johnning<sup>1</sup>, N. Karam<sup>2</sup>, E.T. Hallbäck<sup>2</sup>, I. Adlerberth<sup>2</sup>, E. Kristiansson<sup>1</sup>

<sup>1</sup>The Department of Mathematical Sciences, Chalmers University of Technology, Göteborg, Sweden

<sup>2</sup>The Institute of Biomedicine, University of Gothenburg, Göteborg, Sweden

### **Background**

Carbapenemases are able to hydrolyze carbapenems and, in several instances, almost all other  $\beta$ -lactam antibiotics, making these enzymes a great threat to our ability to treat refractory bacterial infections.

### **Objectives**

In this study, we aimed to determine the genetic context of carbapenemase genes and any additional acquired resistance genes in clinical isolates. We also wanted to study the potential of using whole genome sequencing (WGS) in predicting the antibiotic resistance profiles of multi-resistant isolates.

### **Methods**

Six clinical carbapenemase-positive isolates of five different species (*Acinetobacter baumannii*, *Escherichia coli*, *Klebsiella pneumoniae*, *Proteus mirabilis*, *Pseudomonas aeruginosa*) were selected at the Sahlgrenska university hospital in Gothenburg, Sweden. WGS of selected isolates resulted in draft assemblies that were annotated for mobile antibiotic resistance genes and chromosomal mutations in antibiotic target genes.

### **Conclusions**

We found that several different resistance genes and mutations had been acquired by the isolates. The detected carbapenemase genes included variants *bla*<sub>NDM</sub>, *bla*<sub>OXA-24</sub>, *bla*<sub>OXA-48</sub>, and *bla*<sub>OXA-51</sub>, and some isolates carried multiple variants. From the acquired resistance mechanisms and the intrinsic resistance profile of each species, we could predict a susceptibility profile. The phenotypic resistance profile was determined by measuring the MIC for 37 different antibiotics belonging to all major classes, using E-tests. The results showed good cohesion between the predicted phenotype and measured resistance profile. Our results suggest that WGS can be used to predict the resistance phenotype of carbapenem-resistant isolates. The analysis also underlines the importance of using a comprehensive and curated database of resistance factors for accurate identification the resistance genotype.

#### **SOS INDUCTION OF RCR-FAMILY TRANSPOSASES GENES**

T. Jové<sup>1,2,3</sup>, E. Guérin<sup>1,3,4</sup>, M. Gaschet<sup>1,2,3</sup>, M.C. Ploy<sup>1,2,3</sup>,

<sup>1</sup>U1092, Inserm, Limoges, France

<sup>2</sup>UMR-S1092, Université de Limoges, Limoges, France

<sup>3</sup>Laboratoire de Bactériologie-Virologie-Hygiène, CHU Dupuytren, Limoges, France

<sup>4</sup>GenoLim FR 3503 GEIST, Université de Limoges CHU Dupuytren, Limoges, France

### **Background**

Our work focused on ISCR, a family of insertions sequences encoding RCR transposases thought to catalyze the a rolling-circle (RC) mechanism transposition of their IS elements. The prevailing ISCR, termed ISCR1, are associated to variable combinations of antibiotics resistance genes. The recent discovery of free forms of ISCR1 elements suggests their contribution to the dissemination of these genes.

### **Objectives**

Nothing is known about the expression of the RCR1-encoding gene *rcr1*. This gene displays a conserved s<sup>70</sup> promoter and a putative binding box (operator) for the LexA protein, the regulator of the SOS response. We therefore investigated the SOS induction of the expression of *rcr1*.

### **Methods**

Translational fusions *Prcr1-lacZ* with a wild type or a mutated LexA box were constructed. The activity of the *Prcr1* promoter was estimated using b-galactosidase assays performed in an *E.coli*  $\Delta lacZ$  strain or its derivative  $\Delta lexA$ , after treatment with an SOS-inducer or not.

### **Conclusions**

An activity from *Prcr1-lacZ* could be detected either in the  $\Delta lexA$  strain or upon exposure to mitomycin C unless in strains deficient for the SOS response ( $\Delta recA$ ). RNA techniques allowed us to map the *Prcr1* promoter that was also supported by mutation of the deduced -10 element.

Bioinformatics analyses suggested LexA could regulate more RCR transposases genes and we confirmed it with a recently identified transposase.

Our results highlight a SOS induction of *rcr* genes, suggesting that the mobility of their cognate mobile elements could be triggered upon exposure to some antibiotics or single-strand generating horizontal gene transfer events.

**EPIDEMIOLOGIC CHARACTERIZATION OF NDM-1-PRODUCING ESCHERICHIA COLI AND KLEBSIELLA PNEUMONIAE ISOLATES IN TURKISH HOSPITALS**

O. Karatuna<sup>1</sup>, D.E. Kaya<sup>1</sup>, S. Kocagöz<sup>2</sup>, S. Öktem Okullu<sup>1</sup>, N. Ünübol<sup>1</sup>, I. Akyar<sup>1</sup>, T. Kocagöz<sup>1</sup>

<sup>1</sup>Medical Microbiology, Acibadem University School of Medicine, Istanbul, Turkey

<sup>2</sup>Infectious Diseases, Acibadem University School of Medicine, Istanbul, Turkey

**Background**

Enterobacteriaceae isolates producing New Delhi metallo-beta-lactamase-1 (NDM-1) are considered as a major health threat. We investigated the epidemiology of NDM-1-producing isolates among carbapenem-resistant *Escherichia coli* and *Klebsiella pneumoniae* isolates submitted to a central laboratory from various Turkish hospitals.

**Objectives**

NDM-1 is a class B metallo-beta-lactamase conferring high-level resistance to beta-lactam antimicrobials including carbapenems and is transferable through plasmids. *bla*<sub>NDM-1</sub> positive Enterobacteriaceae are being reported from Turkish hospitals but the epidemiological characterization of these isolates is lacking. This study investigates the prevalence and clonal relationship of *bla*<sub>NDM-1</sub> positive isolates among carbapenem-resistant *E. coli* and *K. pneumoniae* collected from six major Turkish cities (Istanbul, Ankara, Bursa, Adana, Eskisehir, Kocaeli) between September 2011-March 2014.

**Methods**

We detected 143 carbapenem-resistant isolates (*E. coli*, n=28; *K. pneumoniae*, n=115) and a multiplex PCR assay targeting *bla*<sub>OXA-48</sub>, *bla*<sub>NDM-1</sub>, *bla*<sub>IMP</sub>, *bla*<sub>VIM</sub> and *bla*<sub>KPC</sub> genes was performed for these isolates. *bla*<sub>NDM-1</sub> was identified in 24 (16.7%) isolates (*E. coli*, n=4; *K. pneumoniae*, n=20). Pulsed-field gel electrophoresis (PFGE) of Xba-1-digested genomic DNA was used to assess the clonal relationship among *bla*<sub>NDM-1</sub> positive isolates which revealed 3 and 8 distinct pulsotypes among *E. coli* and *K. pneumoniae* isolates, respectively (Figure 1).

Figure 1. Pulsed-field gel electrophoresis patterns of *bla*<sub>NDM-1</sub> positive *Escherichia coli* and *Klebsiella pneumoniae* isolates

## Conclusions

*bla*<sub>NDM-1</sub> was detected in 14.3% and 17.4% of carbapenem-resistant *E. coli* and *K. pneumoniae* isolates, respectively. The different patterns obtained by the PFGE showed that the infections with NDM-1-producing *K. pneumoniae* are due to intra-institutional spread rather than transfer between institutions.

**Acknowledgement:** This work was supported by TUBITAK for the project entitled 'Observable Real-Time Electrophoresis' (Project No: 113M354).

#### ANTI-MICROBIAL PROPERTIES ON DIFFERENT SOLVENT EXTRACTS OF FOUR HYOSCYAMUS SPECIES FROM TURKEY

C. KESKIN<sup>1</sup>, M. YAVUZ<sup>2</sup>, A. DUNDAR<sup>3</sup>, E. KILINC<sup>3</sup>

<sup>1</sup>NUTRITION AND DIETETICS, MARDIN ARTUKLU UNV, MARDIN, Turkey

<sup>2</sup>CHEMISTRY, DICLE UNV, DIYARBAKIR, Turkey

<sup>3</sup>MEDICAL LAB TECHNOL, MARDIN ARTUKLU UNV, MARDIN, Turkey

#### Background

*Hyoscyamus* species contain important tropane alkaloids, such as Hyoscyamine, scopolamine and to lesser extend atropine which have antispasmodic, anticholinergic, analgesic and sedative effects. These compounds are produced mainly by *Hyoscyamus albus* L. This shrub is able to accumulated high amount of tropane alkaloids and these alkaloids indicated antimicrobial activity to microorganisms.

#### Objectives

In this study obtained extracts of some plant species which belongs to *Hyoscyamus* (*Hyoscyamus reticulatus* L., *Hyoscyamus leptocalyx* STAPF, *Hyoscyamus aureus* L., *Hyoscyamus albus* L.) (Solanaceae) family by various solvent systems were researched within the context of their antimicrobial activities.

#### Methods

Antimicrobial activities of hexane, ethylacetate and methanol extracts of *Hyoscyamus* species were tested by disc diffusion method. Gram positive and gram negative standard bacteria strains, clinical isolates and *Candida albicans* (ATCC-10231) yeasts over amoxicillin/clavulanic acid (2:1) ofloxacin, nystatin, imipenem and netilmicin standart antibiotics and 150 µg/6 mm paper disc plant extracts tested.

#### Conclusions

The antimicrobial activity of hexane, ethylacetate and methanol extracts of *Hyoscyamus* species showed different antibacterial activity against tested microorganisms. The diameters of growth inhibition zones of *Hyoscyamus* species ranged from 8 mm to 12 mm. Among all the *Hyoscyamus* extracts studied, methanol extract of *H. reticulatus* and *H. aureus* demonstrated the highest antimicrobial activity versus *S. aureus* (clinic-isolate). *S. aureus* (ATCC-25923), *S. aureus* (clinic-isolate),

and *S. pyogenes* (ATTC-19615) were sensitive to all *Hyoscyamus* extracts except *H. leptocalyx*.

**Antimicrobial resistance**

**ANTIMICROBIAL RESISTANCE- AND CONSUMPTION SURVEILLANCE – A 12-YEAR HOSPITAL EXPERIENCE**

E. Keuleyan<sup>1</sup>, S. Tete<sup>1</sup>, T. Anakieva<sup>1</sup>, M. Valentinova<sup>1</sup>, D. Panayotova<sup>1</sup>

<sup>1</sup>Clinical Microbiology Dept., Medical Institute - Ministry of the Interior, Sofia, Bulgaria

**Background**

During the last years surveillance of Antibiotic resistance (AR) and Antibiotic consumption (AC) became a part of the efforts to contain AR.

**Objectives**

Our aim was to analyze the results of 2002 – 2014 AR and AC surveillance, conducted at a multiprofile tertiary care 300-bed hospital in Sofia.

**Methods**

Etiology of infections and AR were monitored as a part of the national surveillance program BulSTAR. AC was calculated by ABC calc (D. Monnet).

Results. A total of 44786 clinically significant bacteria have been isolated. The first 3 top isolates from urine were *Escherichia coli* (Eco), other *Enterobacteriaceae* (oE-ae), *Enterococcus* spp (Enc); from wounds - *Staphylococcus aureus* (Stau), Eco, Enc; from bacteremia - Eco and oE-ae, Stau and Enc; from the respiratory tract – *Streptococcus pneumoniae* (Spn) and *Haemophilus influenzae* (Hin). The rate of MRSA from wounds was 11 %, but from bacteremia 50 % to 78 %. The most problematic organisms were E-ae with ESBL: they increased from 3.8 % in 2002 through 12 % in 2007 till 26.05 % in 2014. Among Enc there were not VRE; among Spn – the rate of PNSSP was 16.4 %; 10 % of Hin were bla (+). The results from AC showed a fluctuation from 27 to 54 DDD/100 bed-day, with a significant higher AC in the surgical ICU (~ 250 DDD/100 bed-day).

**Conclusions**

Our results illustrated an increase of antimicrobial resistance (ESBL producing *Enterobacteriaceae*) despite the antibiotic policy attempts and suggest for more active actions both nationally and globally.

## **AMINO ACID SUBSTITUTIONS IN GYRA AFFECTS QUINOLONE SUSCEPTIBILITY IN *SALMONELLA* TYPHIMURIUM**

S. Kongsoi<sup>1</sup>, K. Yokoyama<sup>2</sup>, C. Nakajima<sup>1</sup>, R. Changkwanyeeun<sup>1</sup>, K. Changkaew<sup>1</sup>, A. Suprasert<sup>3</sup>, F. Utrarachkij<sup>4</sup>, O. Suthienkul<sup>4</sup>, Y. Suzuki<sup>1</sup>

<sup>1</sup>*Division of Bioresources, Hokkaido University Research Center for Zoonosis Control, Sapporo, Japan*

<sup>2</sup>*Central Research Laboratory, Kissei Pharmaceutical Co. Ltd, Nagano, Japan*

<sup>3</sup>*Department of Anatomy, Faculty of Veterinary Medicine Kasetsart University, Bangkok, Thailand*

<sup>4</sup>*Department of Microbiology, Faculty of Public Health Mahidol University, Bangkok, Thailand*

### **Background**

Amino acid substitutions have generally been found within the quinolone resistance determining regions in subunit A of DNA gyrase (GyrA) of *Salmonella* Typhimurium, but direct evidence of the contribution of these substitutions to quinolone resistance remains to be shown.

### **Objectives**

To clarify the significance of amino acid substitutions in *S. Typhimurium* GyrA to quinolone resistance, we expressed recombinant wild-type (WT) and S83F, D87N, D87G, D87Y and S83F-D87N mutant gyrases in *Escherichia coli* and characterised them *in vitro*.

### **Methods**

WT and mutant gyrases were reconstituted *in vitro* by mixing recombinant subunits A and B. Correlation between the amino acid substitutions and resistance to quinolones ciprofloxacin, levofloxacin, nalidixic acid and sitafloxacin was assessed by the quinolone-inhibited supercoiling assay.

### **Conclusions**

We concluded that amino acid substitutions at position 83 and 87 of GyrA, and quinolone structural variations at position 8 influenced the interaction between DNA gyrases and drugs. Furthermore, we suggest that sitafloxacin might be a choice for the treatment of salmonellosis caused by ciprofloxacin-resistant *S. Typhimurium*.

**Antimicrobial resistance**

## **PHYSIOLOGICAL CHARACTERIZATION OF SHV14 BETA-LACTAMASE OF KLEBSIELLA PNEUMONIAE**

G. Kumar<sup>1</sup>, S. Nathan<sup>1</sup>, A. Ghosh<sup>1</sup>

<sup>1</sup>*Biotechnology, Indian Institute of Technology Kharagpur, Kharagpur, India*

### **Background**

*Klebsiella pneumoniae* (KP) is an opportunistic pathogen of *Enterobacteriaceae* family and is resistant to many antibiotics, especially the beta-lactams, due to extensive production of beta-lactamases. SHV-14 is one of the potent extended-spectrum serine beta-lactamases present chromosomally in *K. pneumoniae*.

### **Objectives**

Physiological characterization of the membrane bound form of *bla*SHV-14 in *K. pneumoniae* and study its effect on antibiotic resistance and biofilm formation.

### **Methods**

Membrane bound form of *bla*SHV14 gene was cloned in pBAD-18 Cam vector and transformed in *ampC* deleted CS109 *Escherichia coli* strain for *in vivo* studies. Minimum Inhibitory Concentration (MIC) was determined in accordance with Clinical and Laboratory Standards Institute (CLSI) using the micro-broth dilution technique. Beta-lactamase activity of cloned *bla*SHV14 was checked by monitoring hydrolysis of a chromogenic substrate nitrocefin at particular time interval in *E.coli* CS109 cell lysate. Biofilm formation on polystyrene surface was also studied by staining the biofilms formed with 0.1% crystal violet stain. An elevated level of beta-lactamase hydrolytic activity was observed against penicillin and cephalosporin group of antibiotics in the presence of *bla*SHV14 in *ampC* deleted CS109. Beta-lactam resistance was increased by eight fold against cephalosporin and 14 fold against penicillin group of antibiotics as compared to the control lacking *bla*SHV14 gene. Biofilm formation index of *ampC* deleted CS109 harbouring *bla*SHV14 gene showed three fold increments as compared to control devoid of *bla*SHV14 beta-lactamase.

### **Conclusions**

Therefore, the presence of *bla*SHV14 gene in *Klebsiella pneumoniae* makes the cell resistant to beta-lactam group of antibiotics and subsequently enhances biofilm formation.

**FEMS-2938**

**Antimicrobial resistance**

## **ESCHERICHIA COLI FROM BLUE MUSSELS (MYTILUS EDULIS) AS INDICATORS FOR ANTIBIOTIC RESISTANCE**

B.T. Lunestad<sup>1</sup>, D. Hjertaker Grevskott<sup>2</sup>

<sup>1</sup>*Contaminants and Biohazards,*

*National Institute of Nutrition and Seafood Research, Bergen, Norway*

<sup>2</sup>*Department of Biology, University of Bergen, Bergen, Norway*

### **Background**

Antibiotic resistance in bacteria is an increasing challenge in all situations where such agents are applied. Blue mussels (*Mytilus edulis*) are suspension feeders and may retain particles with close to 100% efficiency. An adult blue mussel (60 mm in shell length) may clear between 12 and 240 litre of seawater per day for particles containing bacteria. According to the current EU regulations (EU Directive 854/2004), farm sites for cultivation of bivalves must be classified according to their suitability in terms of microbiological and chemical water quality. One of the parameters to be examined is the concentration of *Escherichia coli* in the soft parts and mantle water of the bivalves.

### **Objectives**

*E. coli* derived from animals or man by sewage or land runoff, may subsequently be filtered out by Blue mussels and can be used as indicators for the antibiotic resistance status and detect spatial and temporal changes in resistance prevalence.

### **Methods**

The Norwegian Food Safety Authority submit annually approximately 300 samples of Blue mussels from over 35 stations along the coast. The number of *E. coli* in these samples are determined by a multiple tube dilution method (Donovan's method, ISO 16649-3). On average 60% of the examined samples harbour *E. coli*, and strains are currently being isolated, and will be characterised.

### **Conclusions**

Isolation and characterisation of the antibiotic resistance profile of *E. coli* from Blue mussels may represent a potential indicator of the long term changes.

**FEMS-2229**

**Antimicrobial resistance**

## **CARRIAGE OF CARBAPENEM-RESISTANT ENTEROBACTERIACAE IN HOSPITAL IN-PATIENTS WITH DIARRHOEA**

N. Mackay<sup>1</sup>, I. Eltringham<sup>1</sup>

<sup>1</sup>*Microbiology, Kings College Hospital, London, United Kingdom*

### **Background**

Due to the rising incidence of carbapenem-resistant Enterobacteriaceae (CRE) in the UK and the increased mortality associated with such infections, it is imperative that adequate infection control measures are in place to limit their spread in hospitals. Despite targeted screening of patients at increased risk of carriage, the overall burden may be underestimated. Thus it is recommended that healthcare facilities with CRE conduct surveillance studies to establish the true burden of infection.

### **Objectives**

Surveillance was performed using diarrhoeal stools from in-patients at a large London teaching hospital to assess whether current screening strategies adequately identify carriers, particularly those posing an increased risk of dissemination.

### **Methods**

In addition to routine investigations, diarrhoea stool samples from in-patients were cultured onto Brilliance CRE medium. Blue or pink pigmented colonies that developed overnight were sub-cultured onto MacConkey agar with an ertapenem disc. Ertapenem-resistant colonies were identified by VITEK 2. *Enterobacteriaceae* with minimum inhibitory concentration values above the screening threshold for meropenem were referred to the national reference laboratory for further testing.

### **Conclusions**

Over seven months, 1013 stool samples from 899 patients were screened. Thirteen colonised patients were identified; a carriage rate of 1.45%. Two carbapenemase producing *Enterobacteriaceae* (CPE) and 11 extended spectrum or AmpC  $\beta$ -lactamase producers with porin loss were isolated. Screening of diarrhoea stools detected a higher proportion of carbapenemase non-producing CRE than routine surveillance swabs (11/889 vs. 4/8663;  $P=0.001$ ). CPEs remain rare in acute healthcare settings, even among patient populations with increased risk of transmission. Current guidance for CRE surveillance is considered adequate.

**FEMS-0858**

## **BETA-LACTAMASES INFLUENCE ESCHERICHIA COLI BIOFILM FORMATION**

D. Mallik<sup>1</sup>, G. Kumar<sup>1</sup>, A. Kumar<sup>1</sup>, A. Ghosh<sup>1</sup>

<sup>1</sup>Biotechnology, Indian Institute of Technology Kharagpur, Kharagpur, India

### **Background**

Drug resistance mechanisms of bacteria are a menace to antibiotic therapy. Antibiotic inactivating enzymes and biofilm formation are prominent bacterial escape routes. The largest group of drug hydrolysing enzymes are beta-lactamases which may influence biofilm formation.

### **Objectives**

Inducible beta-lactamase expression is regulated by the same genes that govern peptidoglycan recycling. We attempt to elucidate the role of these genes in biofilm formation by the beta-lactamase producing *E. coli*.

### **Methods**

Single and double gene deletion mutants of *ampC*, *ampD*, *ampE* and *ampG* in *E. coli* 25113 were created by the one-step gene inactivation method. Serine beta-lactamases (TEM-1, OXA-2, CTX-M-15 and SHV-14) from the nosocomial enterobacterial isolates were cloned and expressed in the parent and mutant strains. The influence of deletions on beta-lactamase expression and subsequent effect on biofilm formation were studied by chromogenic cephalosporin hydrolysis and crystal violet staining, respectively. The drug resistance alteration was enumerated by standard microbroth dilution techniques. It was observed that serine beta-lactamases like TEM-1 and OXA-2 lowered the biofilm formation whereas ESBLs like CTX-M-15 and SHV-14 facilitated it. Deletion of *ampD* showed varied levels of beta-lactamase expression and similar effect was observed in biofilm formation. Nonetheless, overexpression of beta-lactamases in  $\Delta$ *ampE* enhanced biofilm formation by 45% whereas a biofilm reduction of 29% was observed in  $\Delta$ *ampG* mutant as compared to beta-lactamase deficient strain.

### **Conclusions**

We infer that beta-lactamase expression not only enhances beta-lactam resistance but also influences biofilm formation; and the genes *ampD*, *ampE* and *ampG* affect the expression of Class A and D beta-lactamases in *E. coli*.

**Antimicrobial resistance**

**FIRST REPORT OF THE PRESENCE OF OXACILLINASES AND METALLO-BETA-LACTAMASES IN INVASIVE ISOLATES OF CARBAPENEM-RESISTANT ACINETOBACTER BAUMANNII IN VOJVODINA PROVINCE, SERBIA**

D. Medic<sup>1</sup>, M. Mihajlovic-Ukropina<sup>1</sup>, V. Gusman<sup>1</sup>, Z. Jelesic<sup>1</sup>

<sup>1</sup>Microbiology, Institute of Public Health of Vojvodina, Novi Sad, Serbia

**Background**

*Acinetobacter spp.* are the most common invasive isolates from blood in Vojvodina Province. The importance of these microorganisms is an exceptional ability of survival and spread in the hospital environment, as well as the extraordinary capacity to quickly acquire different mechanisms of resistance to a wide variety of antimicrobial agents, including carbapenems.

**Objectives**

To detect the presence of encoded genes for oxacillinases and metallo- $\beta$ -lactamases in carbapenem resistant isolates of *Acinetobacter baumannii* in Vojvodina Province.

**Methods**

The identification to the species level of *Acinetobacter baumannii* was confirmed by PCR detection of *bla*<sub>OXA-51-like</sub>. In 50 carbapenem-resistant *Acinetobacter baumannii* isolates, detection of *bla*<sub>OXA</sub> and *bla*<sub>MBL</sub> gene was conducted by multiplex PCR, as well as the detection of insertion sequences IS*Aba1*.

**Conclusions**

*bla*<sub>OXA-24-like</sub> was detected in 45 carbapenem-resistant *Acinetobacter baumannii* isolates. Twelve isolates were positive for *bla*<sub>OXA-58-like</sub>. The presence of *bla*<sub>OXA-23-like</sub> gene was not detected in any of the isolates. A simultaneous presence of two genes was detected in 43 isolates. Thirty eight isolates were positive for *bla*<sub>OXA-24-like</sub> and *bla*<sub>OXA-51-like</sub> genes and in 5 isolates *bla*<sub>OXA-58-like</sub> and *bla*<sub>OXA-51-like</sub> genes were detected. Seven isolates had three genes, *bla*<sub>OXA-24-like</sub>, *bla*<sub>OXA-51-like</sub> and *bla*<sub>OXA-58-like</sub>. All isolates were PCR positive for IS*Aba1*. The presence of *bla*<sub>IMP</sub> and *bla*<sub>VIM</sub> was not detected in any of the isolates. The resistance to carbapenems in isolates of *Acinetobacter baumannii* in Vojvodina Province is caused by production of OXA-24 and OXA-58 oxacillinases, because metallo- $\beta$ -lactamases were not detected.

#### **COMPARATIVE EFFICACY OF THREE CHLORINE-BASED DISINFECTANTS TO CONTROL PLANKTONIC AND SESSILE ESCHERICHIA COLI**

A. Meireles<sup>1</sup>, F. Mergulhão<sup>1</sup>, L. Melo<sup>1</sup>, M. Simões<sup>1</sup>

<sup>1</sup>Chemical Engineering Department,

LEPABE - Faculty of Engineering of University of Porto, Porto, Portugal

### **Background**

Sodium hypochlorite (SH) is the most common antimicrobial agent used in food industry even if it produces unhealthy and toxic by-products. New chlorine-based decontamination strategies are emerging for the decontamination of fresh products and disinfection of surfaces, such as neutral electrolyzed oxidizing water (NEOW) and chlorine dioxide (CD).

### **Objectives**

The aim of the present work was to assess the effects of three chlorine-based disinfectants (SH, NEOW and CD) on the control of *Escherichia coli* in both planktonic and sessile states. The stability of the disinfectants was also assessed over time.

### **Methods**

Four different concentrations (20, 50, 80 and 100 ppm) were tested on the control of planktonic and sessile *E. coli* cells. Planktonic tests were made by measuring growth inhibition over time. Biofilms were formed on stainless steel surfaces and the efficacy of chlorine-based products was assessed by colony forming units counting. The free chlorine content was also measured over time for each disinfectant tested.

### **Conclusions**

NEOW was the most efficient disinfectant in the control of both planktonic cells and biofilms while SH was the least effective. In terms of free chlorine content in solution/disinfectant stability, SH was the most instable and NEOW was the most stable. In conclusion, NEOW is an effective disinfectant strategy for the control of both planktonic and sessile cells and disinfectant decay was negligible compared to the other disinfectants.

#### **IDENTIFICATION AND EVALUATION OF PEPTIDES FOR ACTIVE AND PASSIVE IMMUNIZATION AGAINST PSEUDOMONAS AERUGINOSA**

M. Michalik<sup>1</sup>, D. Linke<sup>1</sup>

<sup>1</sup>Department of Biosciences, University of Oslo, Oslo, Norway

#### **Background**

*Pseudomonas aeruginosa* is a Gram-negative bacterium, commonly present in the environment, that causes serious health problems when it infects humans and is resistant to many antibiotics and treatments. Patient groups at risk for acquisition of *P. aeruginosa* infections include those with cystic fibrosis (which almost always leads to chronic airway infection), paraplegic, burn and immune systems deficiencies patients. Prevention of infection by vaccination is desirable until today no vaccine has yet obtained market authorization.

#### **Objectives**

This project is aimed at the development of the first peptide-based *P. aeruginosa* vaccine and to test planned techniques. Our goal is to produce high immunogenic response in human body.

#### **Methods**

We have selected short peptides from *P. aeruginosa* surface localized proteins using bioinformatic tools. Now we are using genetic engineering and cloning to put those peptides into stable protein scaffolds. After stability tests we will try to induce response in animal model and obtain antibodies for further testing with serum samples from cystic fibrosis patients and *Pseudomonas aeruginosa* clinical isolates. To evaluate whether the specific antibodies are protective *in vitro*, we will use opsonophagocytosis assays.

Finally, we will perform *in vivo* infection experiments in animal models after immunization with targets to reveal whether the produces targets are protective against pathogen.

#### **Conclusions**

As this is rather new development method, we are facing problems and we are trying to establish protocols for our purpose, nevertheless project is going forward and we are expecting successful results soon.

**ANTIMICROBIAL ACTIVITY OF NEWLY SYNTHESIZED NI(II) COMPLEXES ON LABORATORY STRAINS OF MICROORGANISMS AND CLINICAL ISOLATES**

M. Milenković<sup>1</sup>, K. Anđelković<sup>2</sup>, M. Milenković<sup>2</sup>, B. Čobeljić<sup>2</sup>, M. Kovačević<sup>3</sup>

<sup>1</sup>Microbiology and Immunology, Faculty of Pharmacy, Belgrade, Serbia

<sup>2</sup>Faculty of Chemistry, Faculty of Chemistry University of Belgrade, Belgrade, Serbia

<sup>3</sup>Microbiology, Beo-Lab, Belgrade, Serbia

**Background**

The escalation of multidrug-resistant (MDR) bacteria is documented to be a serious problem that affects the choice of appropriate antibiotic therapy and increases the probability of unfavorable infection outcome. Resistance has emerged towards all classes of antibiotics leading to a continuous need for producing new drugs. One of the promising methods in coping with bacterial resistance is the use of alternative classes of antimicrobial agents.

**Objectives**

The aim of this study was to investigate the antimicrobial activity of seven newly synthesized Ni(II) complexes.

**Methods**

Minimum inhibitory concentrations (MICs) of complexes were determined by broth microdilution method according to Clinical and Laboratory Standards Institute guidelines (CLSI, 2007). The antimicrobial activity was investigated on eight laboratory control strains of microorganisms: *Staphylococcus aureus* ATCC 25923, *Staphylococcus epidermidis* ATCC 1228, *Bacillus subtilis* ATCC6633, *Escherichia coli* ATCC 25922, *Klebsiella pneumoniae* ATCC 13883, *Pseudomonas aeruginosa* ATCC 27853, *Salmonella abony* NCTC 6017, yeast *Candida albicans* ATCC 10231, and twenty-five clinical isolates of *Escherichia coli* and *Pseudomonas aeruginosa*. All tests were performed in Müller Hinton broth for the bacterial strains and in Sabouraud dextrose broth for the yeast. Complexes were dissolved in 1% dimethylsulfoxide (DMSO) and then diluted to the desired concentrations ranging from 31–1000 micrograms/ml with addition of 0.05% triphenyl tetrazolium chloride as a growth indicator.

**Conclusions**

Two of tested compounds exhibited strong activity against Gram-positive bacteria, moderate activity against standard strains of Gram-negative bacteria and weak activity against clinical isolates of *Escherichia coli*.

## **ELUCIDATING THE ROLE OF UPC2 AND NDT80 TRANSCRIPTION FACTORS IN CANDIDA PARAPSILOSIS AZOLE RESISTANCE**

J. Branco<sup>1</sup>, E. Fonseca<sup>1</sup>, N. Gomes<sup>1</sup>, A. Pinto-Silva<sup>2</sup>, A. Silva-Dias<sup>2</sup>, C. Pina-Vaz<sup>2</sup>, A.G. Rodrigues<sup>2</sup>, I.M. Miranda<sup>2</sup>

<sup>1</sup>Lab. of Microbiology, Faculty of Medicine University of Porto, Porto, Portugal

<sup>2</sup>Lab. of Microbiology and CINTESIS, Faculty of Medicine University of Porto, Porto, Portugal

### **Background**

*C. parapsilosis* is responsible for hospital-acquired infections with remarkable risks especially to neonates and immunocompromised patients. In the past decades, this human pathogen has been ranked as second or third most isolated fungus, depending on the geographical region. Since its incidence is growing, the number of *C. parapsilosis* resistant to azoles has been followed the same trend. Despite *C. parapsilosis* high prevalence, molecular mechanisms associated to azole resistance remain poorly studied. In a pioneer study addressing azole resistance, an overexpression of ergosterol biosynthesis genes, namely *ERG11*, and their regulators, *UPC2* and *NDT80* genes, were identified as main players in posaconazole resistance.

### **Objectives**

The aim of this work was to reveal the importance of *UPC2* and *NDT80* transcription factors in *C. parapsilosis* posaconazole resistance, through control of ergosterol biosynthesis.

### **Methods**

For that, both genes were independently and simultaneously knockout in posaconazole resistant strain BC014R<sub>PSC</sub>, using *SAT1*-Flipper cassette. Thus, *upc2Δ*, *ndt80Δ* and *upc2Δ/ndt80Δ* mutants were generated. These strains were characterized regarding their azole susceptibility profile.

### **Conclusions**

Deleted strains became susceptible to posaconazole, voriconazole and fluconazole. Minimal Inhibitory Concentrations for azoles in *upc2Δ* and *upc2Δ/ndt80Δ* mutants were similar and inferior to those obtained in *ndt80Δ* strain. We conclude that *UPC2*

and *NDT80* genes are both involved in *C. parapsilosis* azole resistance, however the first seems to play a major role.

This study was supported by FEDER, COMPETE and FCT (PTDC/DTP-EPI/1660/2012).

**FEMS-2466**

**PATTERN OF ANTIMICROBIAL RESISTANCE OF BRUCELLA SPECIES  
ISOLATED FROM CLINICAL SPECIMENS OF BRUCELLOSIS  
PATIENTS, KASHAN-IRAN**

*R. Razzaghi<sup>1</sup>, R. Rastegar<sup>1</sup>, M. Nazeri<sup>1</sup>, M. Momen-Heravi<sup>1</sup>, M. Erami<sup>1</sup>*

*<sup>1</sup>infectious disease, Kashan University of Medical Sciences, Kashan, Iran*

**Background**

Brucellosis is an important health problem in our country in aspect of long lasting treatment and tendency to relapse. Getting information about the pattern of brucella antibiotic susceptibility help us to treat patients more successfully

**Objectives**

This study was done to assess antibiotic susceptibility pattern of brucella with E-test method in Kashan region

**Methods**

This descriptive study was performed on 48 clinical samples were positive culture for brucella in Kashan shahid Beheshti hospital in 2013. Clinical samples got from patients suspicious to brucellosis and Minimum inhibitory concentrations was calculated for ciprofloxacin, doxycycline, rifamin , azithromycin, ceftriaxone, streptomycin and cotrimoxazol with E-test. For each sample a form contain of information about age, sex, clinical manifestation and E-test results was filled. All informations were entered in SPSS 16 software. Results were shown as descriptive statistics.

**Conclusions**

All brucella isolates were sensitive to antibiotics, without any report of resistance. Cotrimoxazol with MIC<sub>50</sub>:0.016, MIC<sub>90</sub>:0.064 was the most effective choice. Doxycycline the second one, streptomycin had the highest MIC. There was not any statistical relation between patient age, sex, type of reception and antibiotic susceptibility.

Cotrimoxazol and doxycycline as effective drugs on brucella are the best choice for treatment of brucellosis in our region. Streptomycin should be used cautiously because it had the highest MIC against brucella spp in our study.

#### **PHENOTYPIC RESISTANCE TO ANTIBIOTICS IN STAPHYLOCOCCUS AUREUS STRAINS ISOLATED FROM PUBLIC HEALTH STUDENTS.**

E. Moreno<sup>1</sup>, A. Dib<sup>2</sup>, M. Espigares<sup>1</sup>, E. Espigares<sup>1</sup>

<sup>1</sup>*Preventive Medicine and Public Health, University of Granada, Granada, Spain*

<sup>2</sup>*Laboratoire de Gestion de la Santé et Productions Animales, Institut des Sciences Vétérinaire El Khroub Université Constantine 1, Constantine, Algeria*

#### **Background**

*Staphylococcus aureus* is an opportunistic pathogen that colonizes the anterior nares and skin, being one of the most common causes of skin, soft tissue and nosocomial infections.

#### **Objectives**

This study was undertaken to evaluate *S. aureus* carriage in public health students at the Faculty of Pharmacy (Granada, Spain), and phenotypical resistance of the strains to antibiotics.

#### **Methods**

This study was performed on 144 public health students. Sampling was done once between October 2013 and January 2014. Samples were collected from both nares inserting a sterile nasals wab into nostril. The swabs were cultured on Mannitol Salt Agar and incubated at 37°C for 24h. Bacterial identification followed the standard phenotypic methods. Antibiotic susceptibility of isolates was tested by disc diffusion method (EUCAST, 2013). A wide array of antibiotics representing the main groups: penicillins, cephalosporins, aminoglycosides and others.

#### **Conclusions**

*S. aureus* was isolated from 20% (29/144) of the student population. Regarding the penicillin group, 3 of 29 strains did not show resistance to this group. 82.7% of *S. aureus* positive strains demonstrated multiresistances to penicillins and cephalosporins. Among the group of aminoglycosides, 93.1% of strains were multiresistant to them, and 2 strains were found to be sensitive for all antibiotics in this group. Furthermore, all strains of this study proved resistances to nalidixic acid. We may conclude that the strains studied exhibit a broad spectrum of multiresistances, which suggests that the use of some penicillins, cephalosporins and aminoglycosides antibiotics could be ineffective for the treatment of infections caused by *S. aureus*.

#### **ANTIMICROBIAL RESISTANCE AND MOLECULAR CHARACTERIZATION OF AVIAN PATHOGENIC ESCHERICHIA COLI IN BELGIUM.**

I. Mutuku<sup>1</sup>, V. Vandenbroucke<sup>2</sup>, A. Moodley<sup>3</sup>, P. Butaye<sup>4</sup>

<sup>1</sup>Bacteriology, CODA-CERVA, Ukkel, Belgium

<sup>2</sup>Bacteriology Veterinary Laboratory, DGZ-Vlaanderen, Torhout, Belgium

<sup>3</sup>Department of Veterinary Disease Biology, University of Copenhagen, Copenhagen, Denmark

<sup>4</sup>Department of Veterinary Medicine, Ross University, St. Kitts, St Kitts & Nevis

#### **Background**

Avian pathogenic *Escherichia coli* (APEC) causes colibacillosis and significant economic losses in the poultry industry.

#### **Objectives**

To isolate, perform antimicrobial susceptibility testing, serotyping, phylogrouping and molecular characterization of the APEC isolates from Belgium.

#### **Methods**

Antimicrobial susceptibility was tested by micro-broth dilution (TREK diagnostics sensititre plates) using the European Committee on Antimicrobial Susceptibility Testing (EUCAST) breakpoints. Multi drug resistance (MDR) was described as resistance to more than three classes of antimicrobials. O-antigen serotyping was done using 31 different antisera (LREC, Spain). Strains negative for all these serotypes were considered not typeable (NT). The isolates were grouped into A, B1, B2 and D phylo-groups. The microarray (CLONDIAG GmbH, Jena, Germany) system was used to test for virulence and antimicrobial resistance genes.

#### **Conclusions**

The 212 APEC isolates were resistant to ampicillin (61%), ciprofloxacin (58%) and tetracycline (49%). MDR was observed in 135 (64%) of the isolates. 13 (6%) isolates have been presumptively identified as ESBL producing. O-antigen grouping showed that 73 (34%) isolates collectively belonged to sero-group O78, O2, and O1; 65 (31%) to other sero-groups associated with colibacillosis in poultry, and 74 (35%) were NT. The most prevalent phylo-groups were D (42%) and A (40%); 15% were phylo-group B1, while 3% were B2. Genes coding for adhesion factors *fimH* (75%) and Iron acquisition systems *iroC* (57%), *irp2* (52%), were mostly observed.

Antimicrobial resistance is high and a large percentage of the isolates are MDR. APEC strains showed high prevalence of virulence factors that might be associated with greater pathogenic potential.

### **Antimicrobial resistance**

#### **CLASS-I AND CLASS-II INTEGRONS IN MULTIDRUG RESISTANT ESBL AND CARBAPENAMASE PRODUCING ENTEROBACTERIACEAE FROM EGYPT**

E. Newire<sup>1</sup>, S.F. Ahmed<sup>2</sup>, N. Woodford<sup>3</sup>, A.P. Roberts<sup>1</sup>

<sup>1</sup>UCL Eastman Dental Institute, University College London, London, United Kingdom

<sup>2</sup>Research and Science Directorate, US. Naval Medical Research Unit-3, Cairo, Egypt

<sup>3</sup>Antimicrobial Resistance and Healthcare Associated Infections (AMRHA), Public Health England, London, United Kingdom

### **Background**

*Escherichia coli* and *Klebsiella pneumoniae* with Extended-Spectrum- $\beta$ -Lactamase- (ESBL) and carbapenemase-mediated resistance are increasingly reported in hospital and community settings worldwide. ESBL CTX-M-15 and Class-D carbapenemase OXA-48 co-production, plus resistance to other antibiotics, limit treatment options, while integrons support resistance genes expression and movement.

### **Objectives**

To characterize genetic determinants encoding  $\beta$ -lactam resistance in Enterobacteriaceae isolates collected from Egypt, and investigate their association with class-I and class-II integrons.

### **Methods**

One hundred and sixty-nine ESBL-producing *E. coli* and *K. pneumoniae* from nosocomial and community-acquired infections were collected from 10 Egyptian university hospitals in two surveillance studies (Group-1: 65 *K. pneumoniae* 2000-2003, Group-2: 41 *E. coli*, 63 *K. pneumoniae* 2009-2011). Resistance genes and integron integrases were identified by PCR and DNA sequencing. Plasmid located blaCTX-M-15 was identified in 11% (n=7) of isolates from group-1 vs. 97% (n=101) from group-2. Non-metallo-carbapenemase blaOXA-48 was detected in 88% (n=57) of isolates from group-1 vs. 95% (n=99) from group-2. Plasmids displayed a range of different RFLP patterns. Integrase-1 was detected in 83% (n=54) of isolates from group-1 vs. 93% (n=97) from group-2, while Integrase-2 was identified in 97% (n=63) of isolates from group-1 isolates vs. 89% (n=93) from group-2.

### **Conclusions**

We have shown that association between integrases and resistance genes carriage appear to increase over time. The linkage between integrases and blaCTX-M-15, and blaOXA-48 is currently being determined by investigating the first gene cassettes in integrons.

UCIBIO/REQUIMTE - Faculdade de Farmácia Universidade do Porto, Porto, Portugal

<sup>2</sup>BMAC, Botelho Moniz Análises Clínicas (BMAC), Santo Tirso, Portugal

#### Background

The widespread of extended-spectrum beta-lactamase (ESBL)-producing *Enterobacteriaceae* has reignited the interest in old antibiotics, being fosfomycin one of the first therapeutic options for treatment of community acquired urinary tract infections. Resistance to fosfomycin is mostly linked to chromosomal mutations causing reduced fosfomycin uptake, though acquisition of plasmid-mediated fosfomycin resistance genes (*fos*), mainly *fosA3* in isolates from Asia and non-clinical settings has been reported.

#### Objectives

To assess the frequency of plasmid-mediated fosfomycin resistance genes and their genetic background among fosfomycin resistant *Enterobacteriaceae* isolates from a community laboratory from Portugal.

#### Methods

Between August 2012-September 2013, 58 fosfomycin resistant isolates (29 *K.pneumoniae*, 26 *E.coli*, 2 *Proteus mirabilis* and 1 *Morganella morganii*) were identified among 461 ESBL-producing *Enterobacteriaceae*. Antibiotic susceptibility testing was performed by standard methods, including fosfomycin disks supplemented with glucose-6-phosphate. *fos* (*fosA*, *fosA3*, *fosB*, *fosC2*), *bla*<sub>ESBL</sub> and *rmtB* genes were screened by PCR and sequencing. *E. coli* phylogroups and genetic context were investigated by PCR and PCR mapping and sequencing, respectively. Plasmid typing was assessed by PBRT, IncFII typing (FAB formula), I-CeuI-PFGE and hybridization.

#### Conclusions

Although with a low prevalence, we identified in the urine of a 61 year old patient, one *E. coli* (1.7%) isolate of phylogenetic group D<sub>1</sub>, from carrying the *fosA3* gene together with *bla*<sub>CTX-M-15</sub> in an F2:A6:B- IncFII plasmid, which corresponds to the first description of *fosA3* in Europe. Although *aac-lb-cr*, *rmtB* and *bla*<sub>OXA-1</sub> genes were not detected, the *fosA3* gene was located in an IS26-composite transposon, similar to others previously reported in Asia suggesting a common platform.

**IN VITRO ACTIVITY OF AQUEOUS AND METHANOLIC EXTRACTS OF PSIDIUM GUAJAVA, NAUCLEA LATIFOLIA AND BROPHYLLUM PINNATUM AGAINST BACTERIA ISOLATED FROM CHICKEN MEAT**

C. OLATERU<sup>1</sup>, B.M. POPOOLA<sup>2</sup>

<sup>1</sup>DEPT. OF BIOLOGY, THE POLYTECHNIC IBADAN, Ibadan, Nigeria

<sup>2</sup>DEPT. OF MICROBIOLOGY, ADELEKE UNIVERSITY OSUN STATE, OSUN STATE, Nigeria

**Background**

medical knowledge derived from traditional societies has motivated searches for new bioactive molecules derived from plants that show potent activity against bacterial pathogens.

**Objectives**

The present study investigated the antibacterial activity of *Psidium guajava*, *Nauclea latifolia* and *Brophyllum pinnatum* on *Staphylococcus aureus*, *Escherichia coli* and *Salmonella* isolated from fresh and frozen chicken meat sold in Ibadan metropolis.

**Methods**

The samples were processed for isolation, identification and antibiotics susceptibility. The phytochemical components of aqueous and methanolic extracts of the three plants were obtained using column chromatography. Antimicrobial activity of the plants extracts was done using agar well diffusion method.

**Conclusions**

Most of the bacterial isolates were resistant to four or more commonly used antibiotics. All the plant extracts exhibit antibacterial activity; there was a significant difference in the antibacterial activity of the methanolic extract of the plants studied ( $P < 0.05$ ). Among the bacteria tested *Escherichia coli* was the most sensitive while *Psidium guajava* showed extensive inhibition zone. This study reveals that there is high prevalence of multi-drug resistant bacteria in the chicken meat tested and that *Psidium guajava* is potential source of antibiotics for drug development against the bacteria studied.

## **IN VITRO SYNERGISTIC EFFECTS OF COLISTIN, TIGECYCLINE, TOBRAMYCIN AND DORIPENEM ALONE OR IN COMBINATIONS AGAINST CARBAPENEM-RESISTANT ENTEROBACTERIACEAE STRAINS**

B. Ozbek Çelik<sup>1</sup>, E. Mataracı-Kara<sup>1</sup>, S. Er<sup>2</sup>, M. Özdamar<sup>3</sup>, M. Yılmaz<sup>4</sup>

<sup>1</sup>Faculty of Pharmacy Pharmaceutical Microbiology, Istanbul University, Istanbul, Turkey

<sup>2</sup>Pharmacy Faculty, Istanbul Medipol University, Istanbul, Turkey

<sup>3</sup>Microbiology, Anadolu Medical Centre, Kocaeli, Turkey

<sup>4</sup>Medicine Faculty Department of Infectious Diseases and Clinical Microbiology, Istanbul Medipol University, Istanbul, Turkey

### **Background**

The emergence of carbapenem resistance in *Enterobacteriaceae* is an important threat to global health. The reason of prevalence of bacterial resistance to antibiotics continues to increase, infections caused by carbapenem-resistant *Enterobacteriaceae* (CRE) are responsible for high rates of mortality and represent a major therapeutic challenge.

### **Objectives**

The aim of this study was to investigate effective antibiotic combinations against carbapenem-resistant *Enterobacteriaceae* (CRE) strains.

### **Methods**

The minimum inhibitory concentrations (MIC) of doripenem, colistin, tigecycline and tobramycin were determined by microbroth dilution method against 39 clinical strains isolated from patients in the intensive care unit (ICU). Carbapenem resistance mechanisms in these isolates were investigated by PCR technique. The in vitro synergistic activities of tigecycline, colistin, tobramycin and doripenem in double combination were determined by microbroth chequerboard technique and results were interpreted using the fractional inhibitory concentration (FIC) index.

### **Conclusions**

Based on MIC<sub>90</sub>s, colistin (1 mg/l) was the most potent agent, followed by tigecycline (2 mg/l), tobramycin (32 mg/l), and meropenem (32 mg/l). According to PCR studies, carbapenem resistance in tested *Enterobacteriaceae* isolates is most often mediated by OXA-48 type carbapenemases. Additionally six isolates were positive for the

genes encoding VIM and one isolates was positive for the genes encoding KPC. Given that a FIC index of  $\leq 0.5$  is borderline, synergistic interactions were most frequent with tigecycline-tobramycin (31 %). No antagonism was observed. The findings of this study may play a useful role in selecting the appropriate combinations when a single agent is inadequate.

## **SYNERGISTIC EFFECT OF NATURAL COMPOUNDS ON ANTIBIOTICS AGAINST ACINETOBACTER BAUMANNII**

*B. Shin*<sup>1</sup>, *W. Park*<sup>1</sup>

<sup>1</sup>*Environmental Science and Ecological Engineering, Korea University, Seoul, Korea*

### **Background**

Difficulties involved in treating drug-resistant pathogens have created a need for new therapies.

### **Objectives**

In this study, we investigated the possibility of natural compounds as an adjuvant for antibiotics against *Acinetobacter baumannii*.

### **Methods**

Measurement of the fractional inhibitory concentration (FIC) for OA demonstrated that it only synergizes with aminoglycoside antibiotics. Other classes of antibiotics (e.g., ampicillin, rifampicin, norfloxacin, chloramphenicol, and tetracycline) have additive effects with OA. Unlike OA, HBA and PP synergize only with chloramphenicol antibiotics. Microarray and quantitative reverse transcription-PCR analysis under OA indicated that genes involved in ATP synthesis and cell membrane permeability, the gene encoding glycosyltransferase, peptidoglycan-related genes, phage-related genes, and DNA repair genes were upregulated. OA highly induces the expression of *adk*, which encodes an adenylate kinase, and *des6*, which encodes a linoleoyl-CoA desaturase, and deletion of these genes increased FICs; these observations indicate that *adk* and *des6* are involved in the synergism of OA with aminoglycosides. Data obtained using 8-anilino-1-naphthalenesulfonic acid, fluorescence-conjugated gentamicin, and membrane fatty acid analysis indicates that *adk* and *des6* are involved in changes in membrane hydrophobicity and permeability. Proton-motive force and ATP synthesis tests show that those genes are also involved in energy metabolism.

### **Conclusions**

We screened 28 natural compounds from plants and confirmed that a pentacyclic triterpenoid, oleanolic acid (OA) could be used only with aminoglycoside antibiotics and other natural compounds (4-hydroxybenzaldehyde and propyl 4-hydroxybenzoate) could be used only with chloramphenicol antibiotics. Taken together, our data show that OA boosts aminoglycoside uptake by changing membrane permeability and energy metabolism in *A. baumannii*.

### **Antimicrobial resistance**

#### **ANTIBIOTIC SUSCEPTIBILITY TESTING OF *SALMONELLA* ENTERITIDIS ISOLATES FROM RAŠKA REGION OF SERBIA**

J. Petković<sup>1</sup>, D. Vidanović<sup>2</sup>

<sup>1</sup>Food Microbiology, Institute of Veterinary Medicine "Jagodina", Jagodina, Serbia

<sup>2</sup>Laboratory Diagnostics, Institute of Veterinary Medicine "Kraljevo", Jagodina, Serbia

#### **Background**

*Salmonella* spp. are zoonotic agents widely spread amongst poultry, cattle and swine which are marked as one of the leading causes of gastroenteritis in humans in the modern world. Today's open market and trade between countries are main reasons of propagation of *Salmonella* serotypes worldwide.

Heavy use of antibiotics in raising animals leads to selective pressure to *Salmonella* serotypes, allowing propagation of resistant serotypes and development or acquisition of genes, gene complexes or mutations which are holders of resistance. Multiresistant *Salmonella* serotypes can transfer resistance genes to other bacterial species.

#### **Objectives**

The aim of this investigation was to determine dominant *Salmonella* serotypes in poultry production in the region of Raška in Serbia and check their resistance to the commonly used antibiotics.

#### **Methods**

*Salmonella Enteritidis* was determined as one of dominant serotypes in the investigated period (2010/2011). Resistance testing was conducted on 41 *Salmonella Enteritidis* isolates. Test method was NLCCS Disk Diffusion Method. Antimicrobial panel comprised of 16 antibiotics.

#### **Conclusions**

Most of the samples were sensitive to all 16 antibiotics. Five isolates were resistant to flumequine and nalidixic acid. Six isolates showed intermediate sensitivity to neomycin and two were intermediate sensitive to tetracycline. This result is not surprising considering fact that these antibiotics are commonly used in poultry production in Serbia. These results suggest that it would be necessary to reassess use of flumequine and limit its use only to cases in which the causative agent had

exhibited resistance to other antibiotics and the bacteriological confirmation of diagnosis and susceptibility testing of pathogens justifies its application.

**Antimicrobial resistance**

**A NEW PROMOTER FOR EXPRESSION OF THE AAC(6')-IB-CR GENE IN CLASS 1 INTEGRONS.**

S. RAHERISON<sup>1</sup>, T. JOVE<sup>1</sup>, M. GASCHET<sup>1</sup>, A. TABESSE<sup>1</sup>, C. TORRES<sup>2</sup>,  
M.C. PLOY<sup>1</sup>

<sup>1</sup>Faculté de Médecine, INSERM UMR-S1092, Limoges, France

<sup>2</sup>University of La Rioja, Biochemistry and Molecular Biology, Logroño, Spain

**Background**

Class 1 integrons are genetic elements able to acquire, exchange and express gene cassettes mainly encoding antibiotic resistance. GCs are usually promoterless and are expressed from a common promoter Pc. Thirteen Pc variants of different strenghts have been described, including a weak (PcW) variant. The *aac(6')-Ib-cr* gene, conferring resistance to aminoglycosides, norfloxacin and ciprofloxacin, is mostly found at first position in class 1 integrons. A 101-bp sequence upstream of *aac(6')-Ib-cr*, contains a putative promoter (named P<sub>A</sub> in this study) suggesting a an expression control by both Pc and P<sub>A</sub>.

**Objectives**

The role of respectively Pc and P<sub>A</sub> in expression of *aac(6')-Ib-cr* will be evaluate.

**Methods**

A 484-bp fragment, from a clinical class 1 integron (*Klebsiella pneumoniae* C1911) and containing the PcW variant, the P<sub>A</sub> promoter and the first 194-bp of the *aac(6')-Ib-cr* gene cassette, was cloned upstream the *lacZ* reporter gene. Wild-type and mutated promoters-were used. Beta-galactosidase assays and quantification of *lacZ* transcripts were used to estimate the level of *aac(6')-Ib-cr* expression. Mapping of the transcription start site by 5' RACE and characterization the N-terminal amino acids of the protein are in progress.

**Conclusions**

**Both promoters are involved in the transcription of *aac(6')-Ib-cr*. However, the level of transcription is slightly increased (12% with begal assays) when PcW is mutated whereas it is highly decreased (84%) when P<sub>A</sub> is mutated.**

**IN-VITRO EVALUATION OF NISIN ALONE AND IN COMBINATION WITH POLYCATIONIC POLYMERS AGAINST HOSPITAL-ACQUIRED METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS (HA-MRSA) STRAINS**

A. Rami<sup>1</sup>, A. Göpferich<sup>1</sup>, M. Simon<sup>2</sup>

<sup>1</sup>Pharmaceutical Technology, University Regensburg, Regensburg, Germany

<sup>2</sup>Bacteriology, Institute for Medical Microbiology and Hygiene, Regensburg, Germany

**Background**

Nasal colonization by Methicillin-resistant *Staphylococcus aureus* (MRSA) is a problem in the hospital setting due to the required hygienic measures as well as the possibility of developing an infection. Polycationics such as Nisin or Chitosan are known to possess antimicrobial activity against a whole set of different bacteria including *Staphylococcus aureus*. The use of combinations may be one way to increase antimicrobial activity and to reduce side effects at the same time.

**Objectives**

The aim of this study was to investigate whether the use of the antimicrobial lantibiotic Nisin in combination with different types of polyethylenimine and chitosan show an increased antimicrobial effect towards MRSA.

**Methods**

The tested MRSA strains were provided by the Institute of Medical Microbiology and Hygiene Regensburg, Germany. Minimum inhibitory concentration (MIC) values were determined according to the CLSI microdilution broth method and at pH 5.5 to assess the efficacy of the antimicrobials. Likewise checkerboard assays were performed at pH 5.5.

**Conclusions**

Combining the antimicrobial peptide Nisin with the polycationic polymers shows promising activity against MRSA strains. Although no synergism could be detected, additive effects were clearly visible. This may be of advantage for the formulation of drug delivery systems for the treatment of nasal MRSA infections.

## **MOLECULAR DETECTION AND CHARACTERISATION OF METALLO-B-LACTAMASE GENES AND INTEGRONS OF IMIPENEM-RESISTANT PSEUDOMONAS AERUGINOSA**

C. Rasoandrainy<sup>1</sup>, N. Gürler<sup>1</sup>

<sup>1</sup>Medical Microbiology, Istanbul University Istanbul Medical Faculty, Istanbul, Turkey

### **Background**

The increase in the prevalence of carbapenem-resistant *Pseudomonas aeruginosa* isolates, particularly caused by the metallo- $\beta$ -lactamases (MBL) is of great concern in the clinical settings worldwide,

### **Objectives**

Here, we report the detection and identification of MBL producing *P. aeruginosa* in our hospital (Istanbul University Medical Center, Turkey), and the characterization of MBL cassette-containing integrons in 90 imipenem-resistant *P. aeruginosa* isolates. Of the isolates investigated in this study, 32 (94%) MBL-positive strains were identified, harboring either *blaIMP* or *blaVIM* genes. The genes detected from MBL-positive isolates were *blaIMP-7*, *aacC1*; *blaVIM-11*; *aacA7*, *blaVIM-2*, *attI*, and *aacA7*.

### **Methods**

In this study, three phenotypic methods, i.e., combined IMP-EDTA disk test (CDT), double-disk synergy test (DDST), and IP/IPI *E*-test) were evaluated for MBL detection in imipenem-resistant *P.aeruginosa* (IRPA) clinical isolates, in comparison to PCR detection of MBL genes as the gold standard. Integrons and their associated gene cassettes were characterized and the genetic relatedness of the isolates was investigated using random amplification of polymorphic DNA (RAPD) analysis.

### **Conclusions**

This study highlights the resistance to imipenem due to IMP- and VIM-producing *P. aeruginosa* and their associated class 1 integrons. Horizontal dissemination of the class 1 integron-associated MBL genes may contribute to the further emergence of carbapenem resistance in other Gram-negative bacteria. Therefore, appropriate surveillance and control measures are essential to prevent the further spread of MBL-producing organisms in hospitals. Further studies should be carried out to give a

better understanding of the impact of integrons on the dissemination of antimicrobial resistance in the clinical settings.

#### DETECTION OF AGR SYSTEM AND ANTIMICROBIAL RESISTANCE IN *S. EPIDERMIDIS* PRODUCER BIOFILM ISOLATED OF AN UNIVERSITY HOSPITAL OVER 20 YEARS.

M.L. Ribeiro de Souza da Cunha<sup>1</sup>, V.C. Pereira<sup>1</sup>, L. Pinheiro<sup>1</sup>, C.I. Brito<sup>1</sup>, A. Oliveira<sup>1</sup>, K.B. Martins<sup>1</sup>, D.F.M. Riboli<sup>1</sup>

<sup>1</sup>Microbiologia e Imunologia, UNESP - Biosciences Institute, Botucatu, Brazil

### Background

*S. epidermidis* isolated from blood culture is highly important in a hospital.

### Objectives

To establish the *agr* locus, the susceptibility of biofilm-producing *S. epidermidis* specimens to antimicrobial agents, and to analyze the clonal profile of *S. epidermidis* isolated from blood culture from an University Hospital, Brazil, along a 20-year period.

### Methods

Detection of biofilm-related genes (*icaA*, *icaB*, *icaC* and *icaD*, *bhp* and *aap*) by polymerase chain reaction (PCR) and expression by reverse transcriptase polymerase chain reaction (RT-PCR) showed 83.6% of *ica* operon, 11.5% of *bhp* gene, and 32.8% of *aap* gene for 61 *S. epidermidis* specimens. The *agrI* and *agrII* loci were detected in 77% and 19.7%, respectively. Oxacillin-resistance was verified by detection of *mecA* gene in 90.1%, and the minimal inhibitory concentration (MIC) values assessed by E-test have shown 83.6% resistance to oxacillin. Clonal profile determination showed 11 clusters, and the ST2 type was determined to be the major cluster.

### Conclusions

The ability of *S. epidermidis* to produce biofilm has been shown, with predominant *agrI* locus, oxacillin-resistance, and highest prevalence of SCC*mec* type III. Some isolates showed resistance to newer antimicrobial agents, and molecular type determination revealed clones persisting for up to 17 years. The major one was the *S. epidermidis* ST2 invasive clone, pointing to the relevance of considering such

organisms as important pathogens with potential ability to cause serious infection in inpatients, as well as taking into account the potential dissemination of such resistant pathogenic clones in hospital settings.

**Antimicrobial resistance**

**RESPONSE TO ENVELOPE STRESS BY THE ZRAP/SR SYSTEM IN  
ESCHERICHIA COLI**

K. ROME<sup>1</sup>, E. Gueguen<sup>1</sup>, J. Covès<sup>2</sup>, A. Rodrigue<sup>1</sup>

<sup>1</sup>Biosciences, MAP UMR 5240 CNRS INSA UCB, Villeurbanne cedex, France

<sup>2</sup>Biosciences, Institut de Biologie Structurale, Grenoble, France

**Background**

To detect and respond to cell envelope damages, Gram-negative bacteria possess multiple envelope stress pathways. The *E. coli*, ZraPSR system is composed of a two component system ZraSR that comprises a membrane associated sensor kinase ZraS and a cytoplasmic response regulator ZraR. This system has the particularity to encompass a third component, the periplasmic protein ZraP. The *zraP* gene is up-regulated by ZraR in the presence of zinc. Moreover, the deletion of *zraP* in *Salmonella typhimurium* dramatically affected its resistance to polymyxin B, a cationic antimicrobial peptide (Appia-Ayme *et al*, 2012).

**Objectives**

A connexion might exist between Zn(II) metabolism and antibiotics sensitivity, mediated by the ZraPSR system. In this study, we investigated this connexion and the ZraPSR signaling pathway in *E. coli*.

**Methods**

WT and  $\Delta zraP$  strains were phenotypically tested for their drug susceptibility profiles.  $P_{zraP}::lux$  and  $P_{zraSR}::lux$  transcriptional fusions were monitored in the presence of metals and drugs. Minimal inhibitory concentrations of zinc, copper, lead and antibiotics were determined for  $\Delta zraP$ ,  $\Delta zraS$  and  $\Delta zraR$  *E. coli* strains.

**Conclusions**

At high zinc concentrations, the expression levels of the two divergent operons *zraP* and *zraSR* increased by 100- and 40- fold, respectively. This suggested that the ZraPSR system is involved in zinc homeostasis. However we showed that high metal concentrations do not affect the survival rate of any *zraP*, *zraS* or *zraR* mutants. In contrast, these *zraPSR* mutants were more sensitive to some envelope targeting antibiotics. This indicates that ZraPSR contributes to the envelope stress response of *E. coli*.

#### IDENTIFICATION OF DIVERSE CAPSULAR TYPES IN MULTIDRUG-RESISTANT (MDR) KLEBSIELLA PNEUMONIAE CLONES USING WZI SEQUENCING AND FTIR

*C. Rodrigues*<sup>1</sup>, *R. Branquinho*<sup>1</sup>, *C. Sousa*<sup>2</sup>, *L. Neves de Andrade*<sup>3</sup>, *E. Machado*<sup>4</sup>,  
*A. Darini*<sup>3</sup>, *A. Novais*<sup>1</sup>, *L. Peixe*<sup>1</sup>

<sup>1</sup>UCIBIO/REQUIMTE. Faculdade de Farmácia Universidade do Porto,  
Laboratório de Microbiologia, Porto, Portugal

<sup>2</sup>Center of Biological Engineering, University of Minho, Braga, Portugal

<sup>3</sup>Laboratório Especial de Bacteriologia e Epidemiologia Molecular (LEBEM),  
University of Sao Paulo, São Paulo, Brazil

<sup>4</sup>Faculdade de Ciências da Saúde Universidade Fernando Pessoa, CEBIMED/FP-  
ENAS, Porto, Portugal

#### Background

*Klebsiella pneumoniae* polysaccharide capsule is a well-known determinant of virulence and pathogenicity, but their identification by conventional methods is laborious and time-consuming. A genotypic-based method has been proposed for capsular typing based on *wzi* sequencing, one of the genes from the *cps* cluster. Identification of capsular types in MDR *K. pneumoniae* high-risk clonal groups suggested intraclonal diversity but it has mainly been explored for carbapenemase-producing CG258 isolates.

#### Objectives

To assess inter and intraclonal diversity of capsular types in a representative collection of MDR *K. pneumoniae* isolates by genotypic, phylogenetic and spectroscopic approaches.

#### Methods

One hundred and four previously characterized MDR *K. pneumoniae* isolates from different clones or CG (ST14, ST15, ST39, ST54, ST101, ST147, ST336, CG258) producing diverse ESBLs and/or carbapenemases were studied. They represent a snapshot of MDR clones responsible for outbreaks or endemic situations in different countries (Brasil, Greece, Poland, Portugal, Romania, Spain). Characterization of capsular types included sequencing and phylogenetic analysis of *wzi* genes (including *wzi* sequences from genomes deposited in NCBI), and Fourier Transform Infrared Spectroscopy (FTIR) coupled with multivariate data analysis (PCA/PLSDA).

#### Conclusions

The diversity of capsular types identified among CG15, CG258 or ST11 isolates highlights an intraclonal diversity that might reflect a suboptimal resolution of MLST-based typing. The clustering of the isolates based on multivariate data analysis of

FTIR spectra according to sequence types and capsular types, which was corroborated by the topology obtained from the phylogenetic tree of *wzi* sequences, suggests the potential application of FTIR for discrimination of *K. pneumoniae* isolates.

## **EFFICACY OF BIOACTIVE COMPOUNDS FROM ACACIA ARABICA AGAINST MULTI-DRUG RESISTANT CLINICAL BACTERIAL PATHOGENS**

L. Rubina<sup>1</sup>, E. Jeyakumar<sup>1</sup>

<sup>1</sup>Microbiology and Fermentation Technology,

Sam Higginbottom Institute of Agriculture Technology & Sciences, Allahabad, India

### **Background**

The emergence of infectious diseases and development of drug resistance in pathogenic bacteria at an alarming rate is a matter of serious concern. Therefore, there is an urgent need to discover novel strategies and identify new antimicrobials from natural substances for development of next generation drugs. Hence screening of novel antibacterial agents was carried out from the bark of *Acacia arabica* with traditional value in ayurvedic medicine.

### **Objectives**

The study aimed to identify bioactive compounds with antibacterial activity isolated from bark extracts of *Acacia arabica*. The inhibitory and cidal concentration of the compounds were evaluated. Further, synergistic effect of potent bioactive compounds with standard antibiotic was determined.

### **Methods**

Bark extracts of *Acacia arabica* were prepared by cold percolation method using polar to non-polar solvents in succession. Antimicrobial activity of the extracts was evaluated using Agar well diffusion method against multi-drug resistant bacteria. Using chromatographic techniques, the bioactive compounds from the extracts were isolated and purified. The purity of the compounds was assessed using high performance liquid chromatography and the compounds were identified using GCMS and NMR spectroscopic techniques. The inhibitory and cidal concentration of the compounds were determined using Resazurin micro-titre assay plate method. The compound exhibiting maximum antibacterial activity with a minimum MIC value was evaluated for synergism with antibiotic.

### **Conclusions**

The results showed that acetone extract was most effective in inhibiting the multi-drug resistant bacterial pathogens. The compounds identified from acetone extract showed positive synergism with antibiotic tested suggesting the possibility of new drug development.

### **Antimicrobial resistance**

#### **NANO-ENCAPSULATED COLISTIN SULPHATE: ANTIPSEUDOMONAL ACTIVITY**

E. Sans<sup>1</sup>, E. Fusté<sup>1</sup>, B. Martínez<sup>1</sup>, M. Pastor<sup>2</sup>, J.L. Pedraz<sup>2</sup>, T. Vinuesa<sup>1</sup>, D. Bachiller<sup>3</sup>, M. Viñas<sup>1</sup>

<sup>1</sup>Pathology and experimental therapeutics, Faculty of medicine, L'Hospitalet de Llobregat, Spain

<sup>2</sup>Laboratory of Pharmaceutics, School of Pharmacy, Vitoria, Spain

<sup>3</sup>Development and Regeneration Program, Fundación Investigaciones Sanitarias Islas Baleares (FISIB), Bunyola (Balearic Islands), Spain

### **Background**

*Pseudomonas aeruginosa* infects the respiratory tract of cystic fibrosis (CF) patients. Multidrug resistant phenotypes and a high capacity to form stable biofilms are frequent. Despite colistin-resistance is infrequent, often emerges in patients treated with inhaled formulations for long periods. The use of nanoparticles can contribute to overcome drug resistance mechanisms. Some authors have reported that lipid nanoparticles loaded with aminoglycosides are more effective than free formulations against clinical isolates.

### **Objectives**

The aim was to explore antimicrobial activity of nanoencapsulated colistin (SLN-NLC) versus free drug against *P.aeruginosa* clinical isolates from CF patients and to investigate their efficacy in biofilm eradication.

### **Methods**

10 mg of colistin was mixed with a 5% (w/v) Precirol® ATO 5 dichloromethane solution. Then, the organic phase and Poloxamer 188 at 1% w/v and Polysorbate 80 at 1%w/v were mixed and emulsified by sonication, solvent evaporated and SLNs obtained filtered. NLC were made with Precirol® ATO 5 and Miglyol® 812 as lipid core. Susceptibility of planktonic bacteria to antimicrobials was examined by using the broth microdilution method and time-kill kinetic curves. Minimal Biofilm Eradication Concentration (MBEC) was determined to assess antimicrobial susceptibility of sessile bacteria. Treated and untreated biofilms were visualized by Atomic Force Microscopy (AFM).

### **Conclusions**

Colistin nanoparticles presented slightly higher activity than free drug against planktonic bacteria. On the contrary, nanoencapsulated colistin was much more efficient in the eradication of biofilms than free colistin. Thus, these formulations have to be considered as a good alternative therapeutic option to treat *P. aeruginosa* infections.

## FEMS-1965

#### CANDIDA GLABRATA PHENOTYPIC SWITCHING AND ITS ASSOCIATION WITH ECHINOCANDIN ANTIFUNGAL RESISTANCE.

A. Silva-Dias<sup>1</sup>, J. Branco<sup>2</sup>, C. Pina-Vaz<sup>1</sup>, M.C. Teixeira<sup>3</sup>, A.G. Rodrigues<sup>1</sup>, I.M. Miranda<sup>1</sup>

<sup>1</sup>Microbiology & Center for Health Technology and Services Research (CINTESIS), Faculty of Medicine University of Porto, Porto, Portugal

<sup>2</sup>Microbiology, Faculty of Medicine University of Porto, Porto, Portugal

<sup>3</sup>Biological Sciences Research Group IBB – Institute for Biotechnology and Bioengineering, Instituto Superior Técnico University of Lisbon, Lisbon, Portugal

#### Background

*Candida glabrata* stands up as the second most prevalent pathogen of mucosal and systemic fungal infection, being the non-*albicans* species with the highest mortality rate associated. Since it possesses both innate and acquired resistance against azole antifungal drugs, echinocandins became the first-line therapy in many hospitals. Recently, *C. glabrata* pathogenicity was associated with phenotypic switching, an important virulence attribute in *C. albicans*, but yet poorly characterized in *C. glabrata*.

#### Objectives

We intend to reveal phenotypic switching as a predictor to uncover the emergence of echinocandins antifungal resistance in *C. glabrata*.

#### Methods

Echinocandin resistance induction assays were performed with CBS 138 strain and two clinical isolates. *C. glabrata* strains were daily exposed to the following echinocandins: caspofungin (CSF), micafungin (MCF) and anidulafungin (ANF). Every 5 days of incubation, minimal inhibitory concentrations (MIC) were determined, according to the CLSI protocol M27-A3 S4.

Phenotypic switching assessment was carried out during induction of antifungal resistance, by plating each strain in medium containing phloxine B.

#### Conclusions

At the beginning of induction assays susceptible colonies were Light Pink (LP) or Medium Pink (MP). In all strains, resistance to echinocandins was detected at day 5 and colonies were MP and Dark Pink (DP). The MICs of the different phenotypes were determined and differences in the susceptibility to echinocandins were found: LP and MP colonies remain susceptible and the DP were resistant.

The continuous exposure to serum levels of echinocandins promotes the acquisition of antifungal resistance in *C. glabrata* together with the emerging of phenotypic switching.

#### HIGH VIRULENT CMY-2 AND CTX-M-2-TYPE-PRODUCING *E. COLI* CAUSING COLIBACILLOSIS IN COMMERCIAL TURKEYS FROM BRAZIL

K.C. Silva<sup>1</sup>, M.P.V. Cunha<sup>2</sup>, N. Lincopan<sup>3</sup>, M.G.X. Oliveira<sup>2</sup>, M.C.V. Oliveira<sup>2</sup>, C.R. Gomes<sup>1</sup>, T. Knöbl<sup>2</sup>, A.M. Moreno<sup>1</sup>

<sup>1</sup>VPS-FMVZ, Universidade De Sao Paulo, Sao Paulo, Brazil

<sup>2</sup>VPT-FMVZ, Universidade De Sao Paulo, Sao Paulo, Brazil

<sup>3</sup>Microbiology-ICB, Universidade De Sao Paulo, Sao Paulo, Brazil

#### Background

A high diversity of AmpC and extended-spectrum (ESBL) beta-lactamases has been described in Brazil among isolates from nosocomial and community settings, but this is the first report of these enzymes in turkey Brazilian farms.

#### Objectives

The aim of this study was to characterize ESBL and plasmid-mediated AmpC-producing *E. coli* isolated from commercial turkey in Brazil.

#### Methods

In 2009, 227 *E. coli* strains were isolated from air sac of turkeys condemned by airsacculitis and screened for ESBL and pAmpC production. MICs were determined by microdilution, and beta-lactamases-encoding genes and virulence factors were investigated by PCR. Plasmids were extracted and transformed into Top10 electrocompetent *E. coli* strain (Invitrogen<sup>TM</sup>) followed by direct sequencing. Genetic relatedness of beta-lactamase-positive strains was determined by ERIC-PCR fingerprinting.

#### Conclusions

The *bla*<sub>CTX-M-2</sub> and *bla*<sub>CMY-2</sub> genes were confirmed in four and seven APEC strains, respectively; which were clonally unrelated, showing high MIC to ceftiofur (MIC<sub>50</sub>≥64 mg/L). The *bla*<sub>CMY-2</sub> genotype was associated with the presence of an IncI1 plasmid of approximately 94kb, which showed 98% of similarity with pSTM709 plasmid (Genbank: HG428759.1), identified in *Salmonella* Typhimurium in Uruguay, confirming its spread in Latin America. Much more concerning is the high virulent profile exhibited by these beta-lactamase-producing APEC, which shared the same virulence factors of human ExPEC. In this regard, the dissemination of cephalosporin-resistant bacteria carrying *bla*<sub>ESBL</sub> and/or *bla*<sub>CMY-2</sub> genotypes has the potential to impact both veterinary and human therapeutic treatment options, which requires more surveillance of antimicrobial resistance in bacteria from food-producing animals.

#### **TESTING THE MUTANT SELECTION WINDOW (MSW) HYPOTHESIS WITH GRAM-NEGATIVE BACTERIA EXPOSED TO THE FLUOROQUINOLONES IN IN VITRO DYNAMIC MODELS**

E. Strukova<sup>1</sup>, Y. Portnoy<sup>1</sup>, S. Zinner<sup>2</sup>, A. Firsov<sup>1</sup>

<sup>1</sup>Pharmacokinetics & Pharmacodynamics, Gause Institute of New Antibiotics, Moscow, Russia

<sup>2</sup>Mount Auburn Hospital, Harvard Medical School, Cambridge, USA

### **Background**

According to the MSW hypothesis, resistant mutants are selected at antibiotic concentrations between the MIC and the mutant prevention concentration (MPC). This hypothesis has been tested mainly with fluoroquinolone-exposed Gram-positive pathogens but not Gram-negatives.

### **Objectives**

To test the MSW hypothesis with *Escherichia coli*, *Klebsiella pneumoniae* and *Pseudomonas aeruginosa*, ciprofloxacin pharmacokinetics were simulated in an *in vitro* dynamic model.

### **Methods**

Four strains each of *E. coli* and *Pseudomonas aeruginosa* and three strains of *K. pneumoniae* with MPC/MIC ratio from 4 to 64 were exposed to twice-daily ciprofloxacin for three days over 50-380-fold ranges of the ratio of the area under the concentration-time curve (AUC) to the MIC. Peak antibiotic concentrations were simulated to be close to the MIC, between the MIC and the MPC, and above the MPC.

### **Conclusions**

With all three bacterial species, resistant mutants were enriched at ciprofloxacin concentrations that fell into the MSW for most of the dosing interval but not at concentrations out of the MSW. Both AUC/MIC- and AUC/MPC-resistance relationships were bell-shaped, showing applicability of the MSW hypothesis. These relationships predict highly variable “anti-mutant” AUC/MIC ratios - 525-1070 h (*E. coli*), 560-1800 h (*K. pneumoniae*) and 225-1100 h (*P. aeruginosa*) – and AUC/MPC ratios – 25-100, 28-140 and 7-204 h, respectively.

**Antimicrobial resistance**

**BACTERIAL RESISTANCE STUDIES USING IN VITRO DYNAMIC MODELS: NEW INSIGHT IN THE DESIGN OF “ANTI-MUTANT” ANTIBIOTIC DOSING**

A. Firsov<sup>1</sup>, M. Golikova<sup>1</sup>, E. Strukova<sup>1</sup>, Y. Portnoy<sup>1</sup>, S. Zinner<sup>2</sup>

<sup>1</sup>Pharmacokinetics & Pharmacodynamics, Gause Institute of New Antibiotics, Moscow, Russia

<sup>2</sup>Mount Auburn Hospital, Harvard Medical School, Cambridge, USA

**Background**

*In vitro* models that simulate human pharmacokinetics of antibiotics allow pharmacodynamic comparisons. This approach can be used to examine the abilities of antimicrobials to suppress not only antibiotic-susceptible pathogens but also their resistant mutants.

**Objectives**

To assess the ability of fluoroquinolones, lipo- and glycopeptides to prevent the selection and/or to suppress resistant mutants of *Staphylococcus aureus*, multiple dosing regimens of the antibiotics were simulated in an *in vitro* dynamic model.

**Methods**

A series of monoexponential pharmacokinetic profiles that mimic once-daily administration of moxifloxacin, gatifloxacin, levofloxacin and daptomycin and twice-daily dosing of ciprofloxacin and vancomycin, were simulated with half-lives reported in humans. The simulated ratios of the area under the concentration – time curve (AUC) to the MIC varied in a wide range that includes clinically relevant AUC/MICs.

**Conclusions**

With each agent resistant *S. aureus* mutants were enriched in a concentration-dependent manner. This enrichment was accompanied by concomitant loss in the susceptibility of antibiotic-exposed bacteria. Both in terms of the population data analysis and susceptibility testing, AUC/MIC-resistance relationships were bell-shaped. Based on these relationships, the threshold “anti-mutant” AUC/MIC ratios were predicted. With moxifloxacin and gatifloxacin but not levofloxacin and ciprofloxacin, and with daptomycin and vancomycin, the predicted thresholds were within the clinically attainable AUC/MIC ratios.

<sup>4</sup>WHO Supranational TB Reference Laboratory, Institut Pasteur de la Guadeloupe, Guadeloupe, France

<sup>5</sup>West China Hospital of Stomatology, Sichuan University, Chengdu, China

**Background**

In developing countries, resistance of *Mycobacterium tuberculosis* to streptomycin (STR) is a severe threat to tuberculosis treatment. Mutations in *rpsl*, *rrs*, and *gidB* genes are reported to be related to STR resistance, some of which are suggested to be associated with *M. tuberculosis* lineage, while this association is geographically varied.

**Objectives**

In this study, we aimed to investigate the mutation characteristics of STR resistance and the association between the polymorphism of drug-resistant genes and *M. tuberculosis* lineage in Sichuan, China.

**Methods**

A total of 180 STR-resistant and 47 susceptible *M. tuberculosis* clinical isolates were genotyped by spoligotyping followed by mutation sequencing of *rpsl*, *rrs* and *gidB* genes.

**Conclusions**

No mutation was released in *rpsl* and *rrs* genes among sensitive isolates, while in resistant ones, 150 harbored mutations in *rpsl* or *rrs*, suggesting a correlation between STR-resistance and mutations of these two genes. Mutation K43R in *rpsl* was found to strongly associate with high-level STR resistance ( $P < 0.01$ ), while those in *rrs* and *gidB* potentially contributed to low-level resistance ( $P < 0.05$ ). No significant geneal association was presented between STR-resistance and Beijing genotype, however, Beijing genotype was significantly correlated with high-level STR-resistance, as well as with K43R ( $P < 0.01$ ), indicating that Beijing genotype has an evolutionary advantage under streptomycin pressure. Interestingly, a dual mutation of E92D and A205A in the *gidB* gene was detected in all isolates of Beijing genotype, suggesting this dual mutation have the potential to be used as an effective marker for identifying Beijing genotype.

## **STRAIN DEPENDENT RESPONSE OF CANDIDA ALBICANS ATCC AND CLINICAL STRAINS TO PHOTODYNAMIC INACTIVATION**

A. Taraszkiewicz<sup>1</sup>, B. Bykowska<sup>2</sup>, K.P. Bielawski<sup>1</sup>, J. Nakonieczna<sup>1</sup>

<sup>1</sup>Laboratory of Molecular Diagnostics, Intercollegiate Faculty of Biotechnology UG-MUG, Gdansk, Poland

<sup>2</sup>Department of Dermatology Venereology and Alergology, Medical University of Gdansk, Gdansk, Poland

### **Background**

Yeast infections, caused by *Candida albicans* are health- and life-threatening, especially to patients with chronic diseases or immunodeficiency. Photodynamic inactivation (PDI) can be successfully used to overcome the problem of resistance of microorganisms to classical antimicrobial chemotherapies.

### **Objectives**

The aim of this study was to compare the effect of nine imidazoacridinone (IA) derivatives used as photosensitizing agents in PDI against *C. albicans* ATCC and clinical strains.

### **Methods**

The Quality Control and clinical strains of *Candida albicans* suspensions were treated with IA derivatives (50  $\mu$ M concentration) and irradiated with 50 and 100 J/cm<sup>2</sup>. The light source used was custom made LED lamp (Secure Media Poland), of maximum output power of 630 mW/cm<sup>2</sup>, which emits blue light (405 nm). Cell suspensions kept in the dark were used as controls. After irradiation serial dilutions from 10<sup>-1</sup> to 10<sup>-4</sup> were obtained from every sample and colony forming units/ml (CFU) were determined. Moreover, the accumulation of IAs in 3 ATCC strains was measured using spectrophotometric methods.

### **Conclusions**

The use of IAs in PDI was able to promote a significant antimicrobial effect against the planktonic forms of *C. albicans* (>5 log<sub>10</sub> units reduction in survival). The PDI effect did not exclusively depend on the chemical structure of the photosensitizing compounds or their accumulation in *C. albicans* cells. We could observe very strong strain-dependent response to PDI treatment. Our results showed that PDI outcome did not strictly depend on physico-chemical processes, but biological background of particular strain played also an important role in this reaction.

**Antimicrobial resistance**

**MOLECULAR CHARACTERIZATION AND ANTIBIOTIC SUSCEPTIBILITY OF METICILLIN RESISTANT STAPHYLOCOCCUS AUREUS (MRSA) IN NORTH INDIA, WITH SPECIAL REFERENCE TO COMMUNITY ACQUIRED MRSA**

A. Thakur<sup>1</sup>, P. Ray<sup>1</sup>, S. Jain<sup>2</sup>, N. Sharma<sup>2</sup>

<sup>1</sup>Medical Microbiology, Post Graduate Institute Of Medical Education and Research, Chandigarh, India

<sup>2</sup>Internal medicine, Post Graduate Institute Of Medical Education and Research, Chandigarh, India

**Background**

Infiltration of community acquired meticillin resistant *Staphylococcus aureus* (CA-MRSA) strains into hospitals and hospital acquired (HA) MRSA into community has become a major hurdle leading to poor clinical outcomes. Role of Panton-Valentine leukocidin (PVL) and arginine catabolic mobile element (ACME), previously associated with CA-MRSA, still remains controversial.

**Objectives**

To study relative frequency of CA and HA- MRSA in outpatients, inpatients and to find and correlate presence of PVL and ACME.

**Methods**

Total 147 MRSA isolates were collected from clinical bacteriology lab of a tertiary care hospital. Isolates were characterized by PCR amplification of *mecA*, PVL, ACME genes and staphylococcal cassette chromosome *mec* (SCC*mec*) typing. Patient risk factors, antimicrobial susceptibility profiles and pcr results were compared. A total of 129 MRSA strains were *mecA* positive, and 34 (27.9%) were PVL gene positive. SCC*mec* III were 31 (24%), 41 were SCC*mec* IV (31.78%), and 32 were SCC*mec* V (24.8%). Of all SCC*mec*III strains, multidrug resistant(MDR) - 70%. In SCC*mec* IV, 51.2% were MDR and in *mec*V strains - 31.25% MDR, further supported by presence of risk factors. PVL positivity in case of *mec*III,IV,V was 2.94%,52.9%,41% respectively. ACME *arc*gene was found in 5(3.87%) cases, 2 of 5 were CA-MRSA non MDR isolates without risk factors. ACME *OPP3*gene was absent.

**Conclusions**

This study demonstrated the presence of CA-MRSA in hospital settings and vice versa. *mec*III MDR strains are no longer restricted to hospital settings and *mec*IV, V are frequently found in hospital settings with MDR characteristics. But PVL is still present mostly in *mec*IV and V.

## **CARBAPENEMASE-PRODUCING KLEBSIELLA PNEUMONIAE AND ESCHERICHIA COLI IN SERBIA**

A. Trudic<sup>1</sup>, Z. Jelesic<sup>1</sup>, M. Mihajlovic-Ukropina<sup>1</sup>, D. Medic<sup>1</sup>, B. Zivlak<sup>1</sup>

<sup>1</sup>Department of Microbiology With Parasitology and Immunology,  
Faculty of Medicine University of Novi Sad Serbia, Novi Sad, Serbia

### **Background**

Emergence and dissemination of carbapenemase-producing *Enterobacteriaceae* is rising worldwide, representing a public health threat. Although most European countries have already established their national surveillance programs considering carbapenemase-producing enterobacteria, so far there are no reports from Serbia.

### **Objectives**

The aim of the study was to determine the occurrence and types of carbapenemases in carbapenemase-producing *Klebsiella pneumoniae* and *Escherichia coli* in Serbia.

### **Methods**

Strains of *Klebsiella pneumoniae* and *Escherichia coli* from 14 different hospitals resistant to at least one carbapenem (imipenem, meropenem, ertapenem) were collected from November 2013 to May 2014. In National Reference Laboratory for Susceptibility Testing carbapenem resistance was confirmed. PCR assays were performed for the detection of genes encoding carbapenemases (*bla*<sub>OXA-48</sub>, *bla*<sub>VIM</sub>, *bla*<sub>NDM</sub> and *bla*<sub>KPC</sub>).

### **Conclusions**

Of 125 collected strains 117 (93.6%) were *Klebsiella pneumoniae* and 8 (6.4%) were *Escherichia coli*. Sixty seven (53.6%) strains were obtained from urine, 25 (20%) from blood, 19 (15.2%) from wound secretions and 14 (11.2%) from lower respiratory tract secretions. Seven (87.5%) *Escherichia coli* harbored *bla*<sub>NDM</sub> gene and in one isolate no carbapenemase encoding genes were detected. Gene *bla*<sub>NDM</sub> was found in 34 (29.1%) *Klebsiella pneumoniae*, *bla*<sub>OXA-48</sub> in 10 (8.5%), *bla*<sub>KPC</sub> in 1 (0.9%), and 7 (6%) strains harbored both *bla*<sub>NDM</sub> and *bla*<sub>OXA-48</sub>, while in 65 (55.6%) *Klebsiella pneumoniae* no carbapenemase encoding genes were detected.

In Serbia the most common type of carbapenemase in both carbapenemase-producing *Klebsiella pneumoniae* and *Escherichia coli* is NDM. Carbapenemase-

producing *Klebsiella pneumoniae* and *Escherichia coli* were most frequently isolated from urine.

## **MONITORING OF THE ENTEROCOCCI RESISTANCE MECHANISMS TO AMINOGLYCOSIDES**

S. Tyski<sup>1</sup>, A. Mrowka<sup>2</sup>, J. Osiak<sup>2</sup>, D. Kociszewska<sup>3</sup>, W. Grzybowska<sup>2</sup>

<sup>1</sup>Pharmaceutical Microbiology, Medical University of Warsaw, Warsaw, Poland

<sup>2</sup>Antibiotic and Microbiology, National Medicines Institute, Warsaw, Poland

<sup>3</sup>Microbiological Laboratory,

Prof. W. Orłowski Independent Public Clinical Hospital Postgraduate Medical Education Centre, Warsaw, Poland

### **Background**

*Enterococcus faecalis* and *Enterococcus faecium* are opportunistic bacteria responsible for frequent nosocomial infections. Presently, resistance of enterococci to antibiotics, especially aminoglycosides, glycopeptides and oxazolidinones is becoming a severe clinical problem.

### **Objectives**

The aims of the study were as follows: determination of phenotypic patterns of enterococci resistant to aminoglycosides, detection of genes responsible for above resistance, investigation of relationships between analyzed isolates.

### **Methods**

125 *E. faecalis* and 49 *E. faecium* isolates resistant to aminoglycosides, obtained from clinical materials in one city hospital during period 2009-2012, were investigated. Besides estimation of antibiotic susceptibility patterns, the search for HLAR (gentamicin MIC > 128mg/L and streptomycin MIC > 1024mg/L), HLGR (gentamicin MIC > 128mg/L) and HLKR (kanamycin and amikacin MICs > 512mg/L) phenotypes was undertaken. The presence of the following genes: *aac(6')-Ie-aph(2'')-Ia*, *aph(2'')-Ib*, *aph(2'')-Ic*, *aph(2'')-Id*, *aph(3'')-IIIa*, *ant(4')-Ia*, *ant(3'')-Ia*, *ant(3'')-Ia*, responsible for resistance to aminoglycosides was detected by PCR technique. Clonal distribution and relationship between isolates was investigated by PFGE after bacterial DNA digestion with *Sma*I restrictase.

### **Conclusions**

80% of the analyzed isolates belonged to the HLAR group, remaining isolates possessed phenotype HLGR. HSLR phenotype was not detected. Genetic analysis showed that *aac(6')-Ie-aph(2'')-Ia* gene responsible for the high resistance to

gentamicin and for cross-resistance to other aminoglycosides (except streptomycin) is the most frequently presented gene among the isolates of tested enterococci. The next common gene was *aph(3'')-IIIa*. Restriction genomic DNA fragments analysis showed large genetic diversity of tested isolates.

**FEMS-2993**

**Antimicrobial resistance**

## **ANTIMICROBIAL RESISTANCE OF CLINICAL SALMONELLA STRAINS IN EDIRNE, TURKEY: FOUR YEAR TREND**

O. Unlu<sup>1</sup>, M. Tugru<sup>2</sup>

<sup>1</sup>*Faculty of Engineering and Natural Sciences- Department of Molecular Biology and Genetics, Uskudar University, Istanbul, Turkey*

<sup>2</sup>*Medical Faculty- Department of Medical Microbiology, Trakya University, Edirne, Turkey*

### **Background**

Salmonella is one of the most common pathogens of the gastrointestinal tract for both humans and animals leads to food-borne outbreaks and various infections. Accurate diagnosis and treatment of this important pathogen is only achieved by knowing its serogroup and antibiotic susceptibility.

### **Objectives**

In our study, we tried to reveal the distribution and antibiotic resistance of Salmonella strains in the community, also examined the effectiveness of multiplex polymerase chain reaction in the identification of Salmonella.

### **Methods**

Bacterial identification and antibiotic susceptibility tests of 105 Salmonella strains, isolated from the clinical samples (between 2009-2013), were conducted with VITEK2 (Biomérieux, France) automatized system. Strains were grouped with both slide agglutination by using Salmonella polyvalent and group specific antisera (Plasmatec, UK) and multiplex PCR. Multiplex PCR was performed by using six sets of primers targeting O-antigen synthesising gene regions in A, B, C1, D and E serogroups commonly found in clinical isolates.

### **Conclusions**

O-grouping results revealed that serogroup D(%68) and C1(%23) are the most common causes of Salmonella oriented diarrhea in Edirne, respectively. Multiplex PCR results showed 100% compatibility with serologic diagnosis. The highest level of resistance found against to ampicillin(%16) among all antibiotics. Among four years there is an increasing resistance to cephalosporins, trimetoprim–sulfamethoxazol and fluoroquinolones.

Salmonella serogroup D is the most frequent serogroup isolated in Edirne and emerging resistance to several antibiotics might be a serious health problem in the future. According to our study, also, multiplex PCR is a reliable and reproducible method in O-grouping of Salmonella.

**Antimicrobial resistance**

## **THE ROLE OF REACTIVE OXYGEN SPECIES IN ANTIBIOTIC INDUCED CELL DEATH IN BURKHOLDERIA CEPACIA COMPLEX BACTERIA**

H. Van Acker<sup>1</sup>, T. Coenye<sup>1</sup>

<sup>1</sup>*Faculty of Farmaceutical sciences, Ghent University, Ghent, Belgium*

### **Background**

It was recently proposed that bactericidal antibiotics kill bacteria through a common mechanism involving the production of reactive oxygen species (ROS). However, this mechanisms involving the production of hydroxyl radicals has become the subject of debate. Since the contribution of ROS to antibiotic mediated killing most likely depends on the conditions, differences in experimental procedures are expected to be at the basis of the conflicting results reported in the literature.

### **Objectives**

The goal of this study was to compare methods used to measure the production of ROS and to study ROS production in *Burkholderia cepacia* complex (*Bcc*) biofilms and planktonic cultures.

### **Methods**

Both direct (ROS-specific stainings) and indirect methods (gene-expression analyses, genetic and phenotypic experiments, detection of protein carbonylation and DNA oxidation) to measure ROS were tested and antibiotics belonging to different classes were included.

### **Conclusions**

While some methods were not sensitive enough, others were found to be useful only in some conditions. Since fluorescein based stainings were shown to be pH sensitive and most *Bcc* species, due to resistance need to be treated with antibiotics in high concentrations (which has a marked influence on pH), these dyes cannot be added simultaneously with the antibiotics and control solutions should have the same pH as the antibiotic solutions tested.

Overall our results highlight some methodological key issues to be considered when evaluating the contribution of ROS in antibiotic mediated killing and although not one ideal method could be identified the different methods suggest that ROS is involved in antibiotic mediated killing in *Bcc* species.

**Antimicrobial resistance**

## **COLISTIN-RESISTANT MECHANISMS OF KLEBSIELLA PNEUMONIAE IN TAIWAN**

J.T. Wang<sup>1</sup>, Y.H. Cheng<sup>1</sup>, T.L. Lin<sup>1</sup>, Y.J. Pan<sup>1</sup>, Y.T. Lin<sup>2</sup>

<sup>1</sup>Department of Microbiology, National Taiwan University College of Medicine, Taipei, Taiwan

<sup>2</sup>Division of Infectious Diseases Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan

### **Background**

Colistin is an important antibiotic for the treatment of carbapenem-resistant *Klebsiella pneumoniae* infection.

### **Objectives**

The colistin resistance mechanism(s) of 26 colistin-resistant *K. pneumoniae* strains in Taiwan were studied.

### **Methods**

We detected *pmrH* mRNA expression by RT-qPCR and analyzed sequences of *pmrHFIJKLM* regulators (MgrB, PhoPQ, PmrAB and PmrD).

### **Conclusions**

Determination of the capsular types and multilocus sequence types (MLSTs) of colistin-resistant strains showed that K64 and ST11 were the predominant capsular type (50%) and sequence type (53.9%), respectively. The expression of *pmrHFIJKLM* operons in 25/26 (96.2%) colistin-resistant strains was significantly higher than in colistin-sensitive strains. The promoter and coding regions of *mgrB* were interrupted by a transposon in 5 and 3 strains, respectively, and *mgrB* was absent in 2 strains. Moreover, MgrB Cys28Tyr and Stop48Tyr mutations were observed in 1 and 3 strains, respectively. Site-directed mutagenesis revealed that MgrB Stop48Tyr and PhoQ Leu26Pro mutations in the colistin-sensitive strain NTUH-K2044 increased the mRNA expression of *pmrH* by 5.3-fold and 39.6-fold, respectively, and both mutations increased the NTUH-K2044 minimal inhibitory concentration for colistin by 32-fold. These results suggest that capsule type K64 is the prevalent type in colistin-resistant strains, and interruptions in *mgrB* which increased expression of the *pmrHFIJKLM* operon are major mechanisms contributing to colistin resistance in Taiwan. In addition, novel single amino acid changes in MgrB (Stop48Tyr) and PhoQ (Leu26Pro) were observed to contribute to colistin resistance.

**THE NEW MLS<sub>B</sub> RESISTANCE GENE ERM(45) IS LOCATED ON A GENOMIC ISLAND IN STAPHYLOCOCCUS FLEURETTII**

J.R.K. Wipf<sup>1</sup>, H. Westh<sup>2</sup>, J.B. Nielsen<sup>2</sup>, S. Schwendener<sup>1</sup>, V. Perreten<sup>1</sup>

<sup>1</sup>University of Bern, Institute of Veterinary Bacteriology, Bern, Switzerland

<sup>2</sup>University of Copenhagen, Hvidovre Hospital, Hvidovre, Denmark

**Background**

***Staphylococcus fleurettii* is a commensal of animals which can occasionally cause bovine mastitis. *S. fleurettii* strain JW205 isolated from bovine milk in Switzerland exhibited inducible resistance to macrolide, lincosamide and streptogramin B (MLS<sub>B</sub>) antibiotics suggesting the acquisition of an erythromycin resistance methylase gene (*erm*), but no known Erm determinant was detected.**

**Objectives**

To identify the MLS<sub>B</sub> resistance mechanism of *S. fleurettii* JW205 and determine if it is located on a mobile genetic element.

**Methods**

Whole genome sequencing of strain JW205 and MLS<sub>B</sub>-susceptible strain M404 (Ion Torrent, Illumina); Comparative analysis of both genomes (progressiveMauve); Cloning and expression of a putative MLS<sub>B</sub> resistance gene in *Staphylococcus aureus* RN4220 to demonstrate functionality and inducible expression; Transformation assays by conjugation and electroporation.

**Conclusions**

The new MLS<sub>B</sub> resistance gene *erm*(45) showed 64% aa identity with the nearest related known methylase Erm(B). It was identified on an 11,513-bp novel genomic island in *S. fleurettii* JW205 (ENA acc. no. LN680996). When cloned into *S. aureus*, *erm*(45) confers inducible resistance to macrolide, lincosamide and streptogramin B. Although a circular form of the island was observed, the element could not be transferred into *S. aureus*. Detection of this new methylase emphasized the role of *S. fleurettii* as reservoir of antibiotic resistance genes and demonstrated once again the importance of animal bacteria as pool for novel genetic elements.

**Antimicrobial resistance**

## **RESEARCHANT HUB: A COMPREHENSIVE LITERATURE-BASED ANTIMICROBIAL SUSCEPTIBILITY DATABASE**

M. Wu<sup>1</sup>, B. van Buuren<sup>1</sup>, M. Heenemam<sup>1</sup>

<sup>1</sup>*ResearchAnt Foundation, ResearchAnt Foundation, Rotterdam, Netherlands*

### **Background**

Antimicrobial resistance is an ever-increasing global public health treat. This phenomenon has stimulated a vigorous research on the field of the antimicrobial susceptibilities and new antimicrobials for the treatment of the so-called super-bugs. The decline in the efficacy of the traditionally used antimicrobials is accompanied by the increasing focus on less conventional antimicrobials agents such as plant extracts and experimental compounds. Scientific literature is a rich source containing thousands of either traditionally overlooked or recently discovered antimicrobial compounds. Unfortunately, the potential of these compounds is often not fully exploited. One reason is that literature information is scattered over various sources making the global assessments of the spectra or modes of the action of the compounds difficult.

### **Objectives**

To alleviate the problem of the lack of a comprehensive and centralized antimicrobial susceptibility database, we developed ResearchAnt Hub. RAH is a manually curated database that contains a collection of literature reported antimicrobial susceptibility data. Our compound library contains thousands of experimental compounds with reported antimicrobial activity that hold promise to become the next-generation antimicrobials.

### **Methods**

The antimicrobial susceptibility data was extracted from relevant peer-reviewed scientific journals by manual search and automatic mapping. The taxonomy of the organisms and physical properties of the known compounds were mapped against NCBI and PubChem, respectively.

### **Conclusions**

RAH is the largest antimicrobial susceptibility database to date. It is a tool that can be used for sharing information, search, prediction and discovery of the next-generation antimicrobial agents.

**THE INCIDENCE OF TOXIGENIC CLOSTRIDIUM DIFFICILE ASSOCIATED DIARRHEA IN MEXICAN CHILDREN AND ADULTS HOSPITALIZED.**

M. Camorlinga-Ponce<sup>1</sup>, N. Ortiz<sup>2</sup>, R. Burgos-Alonso<sup>2</sup>, J.M. Morales<sup>3</sup>, J.G. Camacho<sup>3</sup>, J. Torres-López<sup>3</sup>

<sup>1</sup>Unidad de Investigación Médica en Enfermedades Infecciosas y Parasitarias, Hospital de Pediatría Centro Médico Nacional Siglo XXI IMSS, Mexico City, Mexico

<sup>2</sup>Servicio de Gastroenterología,

UMAE Hospital de Especialidades CMN Siglo XXI.IMSS, Mexico City, Mexico

<sup>3</sup>Unidad de Investigación Médica en Enfermedades Infecciosas y Parasitarias, UMAE Hospital de Pediatría CMN Siglo XXI.IMSS, Mexico City, Mexico

**Background.** Toxigenic *Clostridium difficile* is the most common cause of nosocomial diarrhea, and it is usually a consequence of antibiotic treatment. The incidence and mortality rate of *C. difficile* infection have increased remarkably worldwide during the last two decades. In Mexico, *C. difficile* was not considered an important pathogen in children or adults with nosocomial diarrhea. At this time we ignore the incidence and characteristics of the infecting strains.

**Objective.** To study the epidemiology and virulence of *C. difficile* from Mexican children and adults with nosocomial diarrhea.

**Material and methods.** Stools samples were collected from adults and children with nosocomial diarrhea in two tertiary level hospitals in Mexico City. Stools were cultured in cycloserine cefoxitin fructose agar (CCFA), the *C. difficile* toxin B was confirmed by neutralization with antitoxin, and PCR was performed to identify *tcdA*, *tcdB*, *cdtA*, and *cdtB*.

**Results.** We identified *C. difficile* and its cytotoxic activity in 21 (84%) feces from children and 85 (68.5%) from adults. The majority of the fecal supernatants were positive for toxins of *C. difficile*, and strains were positive for *tcdA*, *tcdB*, *cdtA* and *B*. At present, toxigenic *C. difficile* is a common hospitals-acquired infection in Mexico City.

<sup>1</sup>Arboviruses and Viral Haemorrhagic Fevers Laboratory (National. Ref. Lab),  
pasteur Institute of Iran, Tehran, Iran

<sup>2</sup>Haemorrhagic fever reference and research,  
Bernhard Nocht Institute for tropical medicine, Hamburg, Germany

<sup>3</sup>Epidemiology Department, Pasteur Institute of Iran, Tehran, Iran

<sup>4</sup>Wildlife Zoonoses and Vector-  
Borne Diseases Research Group Department of Virology,  
Animal Health and Veterinary Laboratories Agency, London, United Kingdom

**Background**

*Rift Valley Fever Virus (RVFV) is a member of Phlebovirus genus, Bunyaviridea family that cause acute zoonotic viral disease which mostly affect animals (livestock and specially sheep) but can also be a human threat.*

**Objectives**

This disease becomes a concern in Iran after outbreaks in Saudi Arabia and Yemen in 2000s.

**Methods**

In the last decade human and livestock sera have been screened; 1206 ovine, 405 caprine, 325 bovine and 28 camel samples and 37 suspected human sera were tested for RVFV in nine provinces in Iran (Sistan va Baloochestan, Khorasan, Tehran, Isfahan, Fars, Kerman, Kurdistan, Hormozgan and Booshehr).

**Conclusions**

None of these samples were IgG positive. Moreover, among 37 clinically suspected human cases with RVF symptoms, none of these samples were positive for RVFV. Despite no positive cases have been discovered until now, but as Iran is in a high risk region for RVF, the Laboratory of Arboviruses and Viral Hemorrhagic Fevers (National Ref Lab), Pasteur Institute of Iran, continues the surveillance of this acute hemorrhagic fever disease in Iran (in livestock and suspected human).

#### Background

Several *Clostridium* spp. strains cause serious, occasionally lethal illness in humans and animals and can be introduced into biogas plants by contaminated feedstock.

#### Objectives

In order to enlarge the knowledge on the existence and behavior of these pathogens in biogas plants, this study focused (I) on the incidence of Botulinum neurotoxin (BoNT-)producing *Clostridium* spp., *C. difficile*, *C. novyi*, *C. haemolyticum*, *C. septicum* and *C. chauvoei* in process chains of full-scale biogas plants (screening) and (II) on the quantitative development of *C. botulinum* in lab-scale biogas digesters (sentinel chamber experiments).

#### Methods

The pathogens were detected by methods combining cultural enrichment with biomolecular analysis using quantitative Real-time PCR. For the screening, 154 samples were analyzed containing 29% plant substrates (e.g. silages), 11% animal substrates (e.g. manure), 27% main digester slurries and 33% digestion products (second stage digesters, storage tanks).

#### Conclusions

Pathogenic *Clostridium* spp. were not detected in any of the samples, except for *C. novyi* (4% of the samples contaminated) and *C. difficile*, which was found in approx. 50% of the samples, predominantly in animal substrates, digester slurries and digestion products. Sentinel chamber experiments resulted in reduction of *C. botulinum* by 1.3 to 2.8 log<sub>10</sub> units after 63 d (95.4% to 99.8% inactivation, D-value: 34.6 ± 11.2 d) at 38°C and by at least 99.7% already after 3 d (D-value: 1.0 ± 0.2 d) at 55°C, proving that the sanitary quality of the digestate compared to untreated manure concerning *C. botulinum* is improved by mesophilic and thermophilic biogas processes.

**CASE REPORT: FIRST REPORT OF PULMONARY INFECTION CAUSED BY HORMOGRAPHIELLA ASPERGILLATA IN ITALY.**

R. Koncan<sup>1</sup>, G. Nadal<sup>2</sup>, V. Favuzzi<sup>1</sup>, A. Cazzadori<sup>3</sup>, M. Ligozzi<sup>1</sup>, A. Bazaj<sup>1</sup>, A. Sorrentino<sup>3</sup>, G. Lo Cascio<sup>3</sup>

<sup>1</sup>Pathology and Diagnostics, University of Verona, Verona, Italy

<sup>2</sup>Pathology, Azienda Ospedaliera Universitaria Integrata di Verona, Verona, Italy

<sup>3</sup>Pathology and Diagnostics, Azienda Ospedaliera Universitaria Integrata di Verona, Verona, Italy

**Background**

*Hormographiella aspergillata* is a basidiomycete and belongs to the *Psathyrellaceae* family. It is an anamorph of *Coprinopsis cinerea*, which is normally found in compost and sewage. It has been rarely found in human infections, namely a few cases of pulmonary infections and isolated cases of endophthalmitis, endocarditis and sinusitis have been described, mainly in patients with haematological malignancies.

**Objectives**

We report on a case of pulmonary infection caused by *H.aspergillata* in a 26 years old male patient affected by “mixed phenotype acute leukemia” admitted to the University Hospital G.B.Rossi in Verona, Italy. This is the first case of infection caused by this pathogen reported in Italy.

**Methods**

Despite antifungal prophylaxis during hospitalization, Beta-D-Glucan assay resulted in increasingly positive values, followed by a positive result with the Galactomannan assay. Since the patient suddenly complained a severe pain in scapular region, thoracic RX and CT were performed. The CT revealed the presence of a dense mass compatible with a presumptive Aspergillosis in the right lung. After thoracotomy, a proper diagnosis of *H. aspergillata* was reached by morphological analysis of the growth on Sabouraux agar from biopsy specimen and identification of fungal pathogen was confirmed by molecular tools: sequencing and alignment were conducted on PCR products performed using primers for ITS regions and 26S rRNA gene beyond the D1-D2 hypervariable region.

**Conclusions**

In diagnosis of rare etiologic agents in immunocompromised hosts, mostly when no experienced medical microbiologist is promptly available, molecular tools are becoming essential for accurate species identification and proper antifungal therapy.

**PREVALENCE OF INTESTINAL PARASITIC PATHOGENS AND EVALUATION OF REAL-TIME-PCR AND ANTIGEN ELISA RESULTS FOR ENTAMOEBA HISTOLYTICA IN TURKEY, 2001-2014**

O. Koru<sup>1</sup>, R. Araz<sup>1</sup>, M. Tanyuksel<sup>1</sup>, C. Acikel<sup>2</sup>

<sup>1</sup>MICROBIOLOGY, GULHANE MILITARY MEDICINE ACADEMY, ANKARA, Turkey

<sup>2</sup>EPIDEMIOLOGY, GULHANE MILITARY MEDICINE ACADEMY, ANKARA, Turkey

**Background**

Intestinal parasites are two major groups including protozoa and helminths that inhabit the gastro-intestinal tract in humans. They are one of the major health problems of especially poor and under-developed countries.

**Objectives**

This study was undertaken to determine the prevalence of intestinal parasitic infection in patients with diarrhea and non-diarrhea at the Gulhane Military Medical Academy, Military Hospital in Turkey.

**Methods**

This retrospective study reviewed the hospital records of 45,638 patients admitted over a ten-year period from 2001 to 2014. During the study period, 2.33% (1859/79,537) of stool samples were tested positive for sixteen species of intestinal parasites by using standard parasitological techniques. *Giardia intestinalis* (1.47%) was the most common parasitic cause of diarrhea among the patients. Its prevalence appears to be decreasing in recent years. *Blastocystis hominis* (0.98%), *Entamoeba coli* (0.74%) ranked second and third in prevalence, respectively. *Taenia* spp (0.20%) was more common in non-diarrheal samples. The stool *E. histolytica* antigen ELISA method had 20% sensitivity and microscopy had 11.80% sensitivity compared to the results of a real-time PCR method. Majority of patients were aged between 14-50 years. Prevalence of intestinal parasitic infection was lowest in winter (11.20%), gradually increased during the spring, reached peaks of 57.34% between June and October, and gradually decreased to 2.28% in December.

**Conclusions**

These data will help provide accurate estimates of prevalence of intestinal parasites, which are crucial for the development of policies and strategies to enhance their effective control in Turkey.

## **EMERGENCE OF CLOSTRIDIUM DIFFICILE PCR RIBOTYPE 027 IN HOSPITALS OF SILESIA, POLAND**

G. Martirosian<sup>1</sup>, M. Aptekorz<sup>1</sup>, A. Szczegielniak<sup>1</sup>, E. Kuijper<sup>2</sup>, C. Harmanus<sup>2</sup>

<sup>1</sup>Medical Microbiology, Medical University of Silesia, Katowice, Poland

<sup>2</sup>Microbiology, Leiden University Medical Center, Leiden, Netherlands

### **Background**

According to 2014 ECDC surveillance an reemergence of complicated *Clostridium difficile* infection (CDI) caused by PCR 027 ribotype strains was found.

### **Objectives**

The aim of this study was to determine the incidence of CDI in 20 Silesian hospitals and to characterize *C. difficile* isolates from clinical cases.

### **Methods**

In March 2013 to May 2014, 166 stools from patients with clinically suspected CDI were tested by ESCMID algorithm. GDH was tested by CDIFF QUICK CHEK COMPLETE. GDH-positives were examined for toxins by EIA (toxin A/B) and molecular method (IllumiGene) and cultured anaerobically. Antibiotic susceptibility (MIC for 11 antibiotics) was tested with E-tests, (EUCAST interpretation).

### **Conclusions**

Of 160 GDH-positive samples, 140 *C. difficile* strains were isolated, 110 were PCR ribotyped: 91 (82.7%) belonged to PCR 027 ribotype, three (2.7%) of 176 and 014, two (1.8%) of 010 and 1 strain (0.9%) each of 001, 018, 020 and 046. Seven (6.4%) isolates were non-typeable. All 91 PCR 027 strains were susceptible to vancomycin, amoxicillin/clavulanate and piperacillin/tazobactam and resistant to moxifloxacin, ciprofloxacin, imipenem and erythromycin; 42,9% (39/91) showed resistance to clindamycin. Of 91 isolates tested, 31.9% had MIC > 2 mg/l to metronidazole (ECOFF MIC=2 mg/l) and were resistant to rifampicin.

We confirmed the importance of an appropriate algorithm for rapid CDI diagnostics. The high incidence of *C. difficile* 027 ribotype is in agreement with recent reports from other countries, though elevated MIC values to metronidazole warrants further exploration.

<sup>4</sup>The National Reference Laboratory for Diagnostics of the Syphilis, National Institute for Public Health, Prague, Czech Republic

<sup>5</sup>Department of Dermatovenereology, Faculty Hospital Brno, Brno, Czech Republic

### **Background**

Syphilis is a sexually transmitted disease caused by *Treponema pallidum* subsp. *pallidum*. Serological methods are considered to be the standard in syphilis diagnostics. PCR based tests for detection of treponemal DNA are being used more frequently although not routinely.

### **Objectives**

To determine whether the results of PCR detection of treponemal DNA correlate with the results of syphilis serology.

### **Methods**

Swab (n = 179) and whole blood (n = 260) samples were collected from syphilis-seropositive patients during 2004 to 2013 in the Czech Republic and underwent PCR for detection of treponemal DNA (*polA*, *tmpC*, TP0136, TP0548 and 23S rRNA genes). Several methods (RPR, VDRL, TPHA, TPPA, ELISA IgM and IgG tests and Western blot IgM and IgG tests) were used to test patients serology. Statistical analysis was conducted for all serological tests and results of PCR for both swabs and whole blood samples.

### **Conclusions**

PCR detection of treponemal DNA was more frequent in swabs (78%) compared to whole blood samples (41%). Western blot analysis revealed that patients with PCR-positive swabs ( $n = 118$ ) were more frequently IgM positive ( $p = 0.0002$ ). Analysis of 95 patients where both whole blood and swab samples were available showed that most patients with PCR-positive whole blood had also PCR-positive swabs (89%), however, only 56% of patients with PCR-positive swabs had also PCR-positive whole blood ( $p = 0.0074$ ). Success rate of detection of all 5 tested loci correlated in swabs with lower RPR titer values. In contrary, whole blood showed the opposite.

## **REAL-TIME PCR BASED DETECTION OF TROPHYRYMA WHIPPLEI CARRIERSHIP IN THE NETHERLANDS**

T.T. Severs<sup>1</sup>, R.A.V. Dolmans<sup>1</sup>, S. van Marm<sup>1</sup>, C.H.E. Boel<sup>1</sup>, J.G. Kusters<sup>1</sup>

<sup>1</sup>Medical microbiology, University Medical Center Utrecht, Utrecht, Netherlands

### **Background**

Whipple's disease is a rare, potentially fatal multisystemic disorder resulting from infection with the rod-shaped, gram-positive bacterium *Tropheryma whipplei*. Asymptomatic carriership is a precondition of this disease that is thought to be relatively common, but reliable data on the prevalence of carriership are sparse.

### **Objectives**

To investigate the prevalence of asymptomatic *T. whipplei* carriership in the Dutch population.

### **Methods**

364 fecal samples were tested for presence of *T. whipplei* DNA using three different real-time PCR's: PCR 1, a PCR targeting a repetitive chromosomal locus, (Fenollar e.a. 2004. JCM 42:401-403), PCR 2, targeting the *rpoB*-gene (Moter e.a. 2013. JCM 51:3858-3861), and PCR 3, a newly developed PCR targeting a unique VNTR region in the genome of *T. whipplei* (this study). To solve discrepancies between PCR reactions the identity of the amplicons were determined by sequence analysis.

### **Conclusions**

The number of positive samples varied significantly between the three PCR reactions with PCR 1 finding 46/364 (12.6%), PCR 2 23/364 (6.3%), and PCR 3 21/364 (5.8%) positives. Only 19/364 (5.2%) samples were found positive in all three PCR tests. Sequencing data of the samples suggests that none of the 27 discrepant samples of PCR 1 contained sequences that were of *T. whipplei* origin. Also 3/4 discrepant samples for PCR 2 did not contain *T. whipplei* derived PCR products, while the remaining discrepant sample did. For PCR 3 sequencing of the two discrepant revealed one true positive (shared with PCR2) and one false positive. This suggests a true prevalence of 20/364 (5.5 %).

## **OUTER MEMBRANE VESICLES AS PLATFORM VACCINE PRODUCT**

L. van der Pol<sup>1</sup>

<sup>1</sup>*Research, Intravacc, Bilthoven, Netherlands*

### **Background**

Outer membrane vesicles (OMVs) are released spontaneously during growth by many Gram-negative bacteria. OMVs have pathogen-like properties inducing a broad protective immune response in hosts.

Classical vaccines were generally ill-defined products but recent recombinant subunit vaccines are developing towards well-characterized pathogen-like structures. Progress in immunology and microbiology can facilitate selection of components that should be or not be present in a platform OMV vaccine.

### **Objectives**

Evaluation of OMVs from *Neisseria meningitidis* as platform vaccine product.

Characterization of the vaccine OMV product with identified structure-function relationship.

### **Methods**

A number of different assays, such as ELISA, DLS, SDS-PAGE and Biacore aid to predict the OMV quality in the accepted potency assay, the Serum Bactericidal Assay (SBA).

For most cases, genetic engineering of the OMV-producing bacteria can be used to improve their application as vaccines. Used modifications include (I) removal of capsular structures and anchor proteins, (II) overexpression of specific antigens, (III) lipopolysaccharide (LPS) modification, (IV) retention of antigens in the membrane that can be secreted, (V) removal of unwanted immune-modulating components.

Examples of these approaches will be given.

### **Conclusions**

The increased knowledge in microbiology and immunology of OMV from bacterial pathogens will enable the development of well-characterized OMV platform vaccine products, as illustrated for *Neisseria meningitis* OMVs.

<sup>13</sup>Department of Clinical and Experimental Medicine Division of Medical Microbiology, Linköping University, Linköping, Sweden

### Background

Lyme borreliosis (LB) is a common and increasing tick-borne disease in Europe caused by the *Borrelia* bacteria. The risk of acquiring a *Borrelia* infection after a tick bite is not fully known. The transmission of *Borrelia* bacteria from ticks to humans may depend on many factors such as tick-species, life-stage, duration of tick-feeding, *Borrelia* species, number of *Borrelia* bacteria, and site for infestation.

### Objectives

We investigated the incidence of *Borrelia* infection after a bite by a *Borrelia*-positive tick and if the number of *Borrelia* bacteria and/or the duration of tick-feeding influenced the risk of contracting a *Borrelia* infection.

### Methods

During 2008-2009, ticks and blood samples were collected from 1546 tick-bitten persons from Sweden and the Åland Islands, Finland. Follow-up blood samples were taken three months after the tick bite. The duration of tick feeding was microscopically

estimated and *Borrelia* bacteria was detected and quantified in ticks by real-time PCR. Anti-*Borrelia* antibodies were detected in sera using ELISA tests and immunoblot.

### **Conclusions**

One out of four of the participants were bitten by a *Borrelia*-positive tick but only 10% of these developed signs of a *Borrelia* infection (seroconversion and/or LB diagnosis). Those who seroconverted removed “their” ticks significantly later than those who did not. The number of *Borrelia* bacteria in the ticks did not explain the risk of seroconversion. The risk of developing a *Borrelia* infection after a bite by a *Borrelia*-positive tick is small but increases with the duration of tick feeding.

**TOXIN RESISTANCE IN AQUATIC FUNGI POSES ENVIRONMENTALLY FRIENDLY REMEDIATION POSSIBILITIES: A STUDY ON THE GROWTH RESPONSES OF *M. HIEMALIS* EH5 AGAINST MC LR, BMAA AND CYN**

E. Balsano<sup>1</sup>, M. Esterhuizen-Londt<sup>1</sup>, E. Hoque<sup>2</sup>, S. Pflugmacher Lima<sup>1</sup>

<sup>1</sup>Ecological Impact Research and Ecotoxicology, Technische Universität Berlin, Berlin, Germany

<sup>2</sup>Institute of Groundwater Ecology, GSF-

National Research Center for Environment and Health, Neuherberg, Germany

**Background**

Cyanobacteria produce various harmful secondary metabolites, which pose a serious global threat to aquatic ecosystems and human health. Biodegradation is a hot topic of water purification research and offers especially an environmentally friendly remediation strategy.

**Objectives**

The water fungus *Mucor hiemalis* EH5 (*M. hiemalis* EH5) represents a promising biodegrading candidate, as previous studies have shown its ability to breakdown the herbicide isoproturon based on natural metabolic processes and further has been characterized to be resistant to environmental perturbations, such as low temperatures and H<sub>2</sub>S/sulfide pollution, which would facilitate its application even under extreme environmental conditions.

**Methods**

Herein we elucidate the effect of three different cyanotoxins, the hepatotoxin microcystin-LR (MC-LR), the neurotoxin  $\beta$ -N-methylamino-L-alanine (BMAA) and the cytotoxin cylindrospermopsin (CYN), on the susceptibility of *M. hiemalis* EH5 using an adaptation of the Kirby-Bauer disk diffusion assay, and the influence on fungal growth and biomass production *via* radial extension and dry weight measurements.

Additionally, we established an optimized strategy for the individual cyanobacterial toxin extraction from the vegetative part of *M. hiemalis* EH5.

**Conclusions**

The fungal microorganism showed a fast adaptation behavior and strong resistance towards the toxins. No significant differences in terms of growth were perceived compared to an untreated control. This indicates that the cyanobacterial toxins have no toxic effect on the fungus and that the organism can grow and develop undisturbed in their presence. Our results suggest that *M. hiemalis* EH5 is an ideal organism to be tested as a biodegrading system for the remediation of cyanobacterial toxins from contaminated waters.

**TREE SPECIES AFFECT FUNGAL COMMUNITY AND FUNCTIONAL DIVERSITY  
RELATED TO LIGNOCELLULOSE DEGRADATION IN FOREST SOILS**

F. Barbi<sup>1</sup>, L. Vallon<sup>1</sup>, E. Prudent<sup>1</sup>, A. Dubost<sup>1</sup>, L. Fraissinet-Tachet<sup>1</sup>, R. Marmeisse<sup>1</sup>,  
P. Luis<sup>1</sup>

<sup>1</sup>UMR CNRS 5557 Ecologie Microbienne, Université Lyon1, Lyon, France

**Background**

Forest ecosystems play an essential ecological function by storing up to two thirds of the organic carbon. Before being stored in below-ground a large part of this carbon is contained in litter. Therefore, degradation of plant biomass is an essential process for the proper functioning of forest soils and terrestrial carbon cycling. Soil microorganisms and especially saprotrophic fungi are the principal actors of this process as they produce a wide range of extracellular enzymes involved in the decomposition of the main plant organic polymers. Nature of litter is different depending on tree species and affects diversity and composition of fungal community. We therefore hypothesized that fungal communities selected by the different tree species express specific lignocellulolytic enzymes.

**Objectives**

We simultaneously analyzed the effect of tree species (beech vs spruce) on the taxonomic composition of the active fungal community in soils using the Elongation factor I (EF1alpha) and on the diversity of expressed fungal genes encoding three main families of Carbohydrate-Active Enzymes (CAZymes) involved in the degradation of the lignocellulose (GH7, GH11 and AA2).

**Methods**

Environmental cDNA, generated from soil extracted RNA, were used as template to amplify the targeted genes using family-specific primers. All amplicons were sequenced by high-throughput sequencing using Illumina Miseq technology.

**Conclusions**

Results obtained revealed that only a few numbers (less than 20 percent) of taxonomic and functional clusters were detected in both forest soils. Statistical analysis (AMOVA) showed a significant tree species effect on the diversity of the transcript analyzed.

**DIURNAL VARIATION OF BACTERIAL COMMUNITIES IN DRINKING WATER SYSTEMS OVER SMALL SCALES.**

Q.M. Bautista de los Santos<sup>1</sup>, O. Blakemore<sup>2</sup>, J. Schroeder<sup>1</sup>, W. Sloan<sup>1</sup>, A.J. Pinto<sup>1</sup>

<sup>1</sup>*Infrastructure and Environment Research Division, University of Glasgow, Glasgow, United Kingdom*

<sup>2</sup>*United Utilities, United Utilities, Warrington, United Kingdom*

**Background**

The application of next-generation sequencing techniques to the study of microbial communities that inhabit Drinking Water Systems (DWSs) has revealed the presence of a diverse and abundant microbiome. To our knowledge, the seasonal, weekly and monthly variations of the DW microbiome have been explored, while information on diurnal variation is still lacking. Similarly, sampling efforts mostly focus on covering large spatial scales in the DW, while information on DW microbiome over small spatial scales is still limited.

**Objectives**

To investigate the variabilities in the drinking water microbiome originating from: (a) diurnal water use patterns, and (b) small-scale spatial effects.

**Methods**

Triplicate samples of disinfected bulk water (15 to 18L) were taken from 5 sampling locations in Glasgow over 24 hours, in six time periods to capture diurnal effects. The samples were filtered through sterile 0.22µm pore size filters and subject to DNA extraction, triplicate 16S rRNA targeted PCR amplification followed by Illumina MiSeq sequencing. Sequence processing was conducted in Mothur using a previously reported protocol. Statistical analyses were conducted using Mothur and R.

**Conclusions**

Significant differences in richness over a 24-hour period were observed in 3 of the 5 sampling locations. Across sampling locations, a significant difference for the time periods corresponding to higher demand and flows in the system was observed, while differences were not significant for time periods corresponding to lower demand and flows in the system. For all the sampling locations, a change in the community structure and membership throughout the day was observed.

**SUBLETHAL 2,4-DICHLOROPHENOXYACETIC ACID REMODELS CELL ENVELOPE AND ALTERS VITAL PATHWAYS OF CELL METABOLISM IN *E. COLI* AND *RHIZOBIUM LEGUMINOSARUM***

S.V. Bhat<sup>1</sup>, S.C. Booth<sup>2</sup>, E.A.N. Vantomme<sup>1</sup>, S.G.K. Mcgrath<sup>1</sup>, A. Shirin<sup>3</sup>, C.K. Yost<sup>3</sup>, T.E.S. Dahms<sup>1</sup>

<sup>1</sup>Chemistry and Biochemistry, University of Regina, Regina, Canada

<sup>2</sup>Biological Sciences, University of Calgary, Calgary, Canada

<sup>3</sup>Biology, University of Regina, Regina, Canada

**Background**

There is a growing need to characterize the effects of environmental stressors at the molecular level on model organisms with the ever increasing number and variety of anthropogenic chemical pollutants. The herbicide 2,4-dichlorophenoxyacetic acid (2,4-D), one of the most widely applied pesticides in the world, is known to have undesirable effects on nontarget species, but the specific molecular details of these effects at sublethal levels are unknown.

**Objectives**

The model bacterium *Escherichia coli* and the nitrogen fixing, beneficial soil organism *Rhizobium leguminosarum* viciae 3841 (*Rlv*) were used to characterize the specific stress response mechanisms during sublethal 2,4-D exposure.

**Methods**

We designed a unique platform combining advanced microscopy with metabolomics to determine the sublethal effects of 2,4-D on cell morphology, surface molecular organization and physical properties, and specific target pathways in the metabolic network.

**Conclusions**

*E. coli* BL21 and a selection of genotypically diverse *E. coli* strains isolated from the environment exhibited filamentous phenotype and envelope remodelling during low level 2,4-D exposure. Sublethal 2,4-D altered vital pathways of cellular metabolism most of which could be attributed to oxidative stress, consistent with increased reactive oxygen species (ROS). *Rlv* exposed to 2,4-D also showed accumulation of ROS and carbonylated proteins coinciding with adaptive changes to integral pathways of cellular metabolism, envelope remodelling and the potential to assimilate 2,4-D. This study identifies biomarkers of 2,4-D exposure in *E. coli* and *Rlv* and offers valuable insights into the mode-of-action of 2,4-D at sublethal levels in soil bacteria.

**EFFECT OF OCEAN ACIDIFICATION ON RHODOLITH HOLOBIONTS : FREE-LIVING CORALLINE ALGAE AND THEIR ASSOCIATED MICROBIOTA**

G. Cavalcanti<sup>1</sup>, B. Ribeiro<sup>1</sup>, P. Shukla<sup>2</sup>, M. Morris<sup>2</sup>, M. Edwards<sup>2</sup>, F. Thompson<sup>1</sup>, E. Dinsdale<sup>2</sup>

<sup>1</sup>Biology, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

<sup>2</sup>Biology, San Diego State University, San Diego, USA

**Background**

Rhodoliths are free-living coralline algae (*Rhodophyta*, *Corallinales*) that are ecologically important for the functioning of marine environments. They form extensive beds distributed worldwide, providing a habitat and nursery for benthic organisms and space for fisheries, and are an important source of calcium carbonate. Rhodolith beds are large carbon sinks, but the growth of the Rhodolith holobiont may be affected by lower pH, which is predicted to occur in the near future. The term holobiont refers to any organism and all of its associated symbiotic microbes (parasites, mutualists, synergists and amensals), including endobionts and epibionts that perform diverse ecological roles. A holobiont occupies and adapts to an ecological niche, and is able to employ strategies unavailable in any one species alone when challenged by environmental perturbations.

**Objectives**

The main goal of this research was to perform an experiment to test the effects of higher pCO<sub>2</sub> (lower pH) on Rhodoliths holobionts in order to analyze whether the microbial community associated with Rhodoliths is perturbed with a change in pH.

**Methods**

The effect of climate changes, indeed increasing acidification of oceans, on Rhodolith holobiont growth may be due to dissolution of their calcium carbonated skeleton or a change in the microbial community and this was investigate through physiological assays (photosynthesis and calcification) and metagenomics (taxonomical and functional diversity of the holobiont).

**Conclusions**

The outcomes of the research are an increased understanding of microbes associated with Rhodoliths and new hints on how the holobiont might respond to global climate changes.

## **METABOLOMIC PROFILES OF MARINOBACTER ISOLATE J5B1 GROWN ON DIFFERENT NAVAL FUELS**

S. Celikkol-Aydin<sup>1</sup>, E. Aydin<sup>1</sup>, V. Bonifay<sup>1</sup>, J. Sunner<sup>1</sup>, I.B. Beech<sup>1</sup>

<sup>1</sup>Microbiology and Plant Biology, University of Oklahoma, Norman, USA

### **Background**

Replacement of crude oil with its synthetic and biological equivalents is important for environmental and economical reasons. It is essential to assess synthetically produced alternative fuels in terms of bio/degradability and storage conditions in comparison to crude oils.

### **Objectives**

This study investigates the growth of a model marine microorganism in seawater in the presence of different naval fuels and its impact on corrosion of 1018 carbon steel storage tanks.

### **Methods**

Cultures of *Marinobacter* isolate J5B1 were incubated in sterilized Key West seawater augmented with different naval fuels, i.e., F76, JP5, FT-F76 and JP5-Camelina. All cultures contained 1018 carbon steel coupons. Bulk phases of each incubation were sampled periodically for cell count and metabolomes over a period of 80 days. Scanning electron microscopy was employed to characterize surfaces of exposed coupons. Polar organic compounds in neat fuels and their water extracts were analyzed using HPLC-Mass Spectrometry.

### **Conclusions**

*Marinobacter* isolate J5B1 grew in the presence of all tested fuels. HPLC-MS analysis revealed that all neat fuels shared 84 compounds while 21 compounds were common in water extracts of fuels. Fuel F76 was the most and JP5-Camelina was the least diverse in terms of the abundance of polar compounds. Seawater alone could maintain the growth of *Marinobacter* and water soluble compounds of JP5-Camelina were readily utilized by this isolate. Quaternary ammonium compounds detected in F76 fuel were most likely the reason for stunted bacterial growth. While general corrosion of steel coupons was noted in all incubations the highest level of localized attack was observed in cultures augmented with F76.

**GENOMIC, PROTEOMIC AND MORPHOLOGICAL CHARACTERIZATION OF TWO NOVEL BROAD HOST LYTIC BACTERIOPHAGES (PHI)PD10.3 AND (PHI)PD23.1 INFECTING SOFT ROT ENTEROBACTERIACEAE**

R. Czaikowski<sup>1</sup>, Z. Ozymko<sup>1</sup>, V. de Jager<sup>2</sup>, E. Lojkowska<sup>1</sup>

<sup>1</sup>Department of Biotechnology, Intercollegiate Faculty of Biotechnology UG-MUG, Gdansk, Poland

<sup>2</sup>Microbial Ecology, Netherlands Institute of Ecology (NIOO-KNAW), Wageningen, Netherlands

**Background**

*Pectobacterium* spp. and *Dickeya* spp. are necrotrophic bacterial pathogens of many important crops worldwide. The effective strategies to control pectinolytic bacteria have not yet been developed. Consequently, the management of *Pectobacterium* spp. and *Dickeya* spp. is based mainly on the exclusion of infected plant material and the use of hygienic practices during potato cultivation and storage.

**Objectives**

This study reports on the isolation and characterization of broad host lytic bacteriophages able to infect the dominant *Pectobacterium* spp. and *Dickeya* spp. affecting potato in Europe viz. *Pectobacterium carotovorum* subsp. *carotovorum* (Pcc), *P. wasabiae* (Pwa) and *Dickeya solani* (Dso) with the objective to assess their potential as biological disease control agents.

**Methods**

The lytic bacteriophages were isolated from potato samples collected in different potato fields in Poland. Transmission electron microscopy was used to study bacteriophage morphology. The phages were characterized for optimal multiplicity of infection, the rate of adsorption to the bacterial cells, the latent period and the burst size. They were also genotypically characterized with RAPD-PCR and RFLP techniques. The structural proteomes of both phages were obtained by fractionation of phage proteins by SDS-PAGE. Phage protein identification was performed by liquid chromatography-mass spectrometry (LC-MS) analysis. Pulsed-field gel electrophoresis (PFGE), genome sequencing and comparative genome analysis were used to gain knowledge of the length, organization and function of the (phi)PD10.3 and (phi)PD23.1 genomes.

**Conclusions**

This is the first study dealing with isolation and characterization of broad host lytic bacteriophages able to infect dominant *Pectobacterium* and *Dickeya* spp. in potato in Europe.

**HIGH ABUNDANCE OF LEADERLESS MESSENGER RNA TRANSCRIPTS AND A NOVEL RADIATION RESPONSE MECHANISM IN RADIORESISTANT BACTERIUM *DEINOCOCCUS DESERTI***

A. De Groot<sup>1</sup>

<sup>1</sup>*Ibeb, Cea, Saint Paul Lez Durance, France*

**Background**

*Deinococcus* bacteria tolerate very high doses of gamma and UV radiation and other massive DNA damage- and oxidative stress-generating conditions.

**Objectives**

To better understand the mechanisms underlying extreme radioresistance, we characterized the transcriptome of *Deinococcus deserti*. Furthermore, we investigated how IrrE, a protein essential for radioresistance, is involved in upregulation of various genes following irradiation.

**Methods**

Differential RNA sequencing was performed, allowing genome-wide identification of transcription start sites (TSSs). The function of IrrE, which contains a conserved domain of unknown function (COG2856/DUF955), was analysed using several genetic and biochemical experiments.

**Conclusions**

Strikingly, 60% of the identified mRNAs in *D. deserti* is leaderless, with the TSS exactly at or very close to the translation initiation codon (1). Such proportion of leaderless mRNAs is unprecedented for a bacterial species. Numerous additional leaderless mRNAs predicted to encode small peptides were identified, providing a new explanation for the accumulation in the cell of small peptides important for protection of proteins against oxidation and thus for radioresistance. Several novel highly radiation-induced genes were also found. The mechanism by which IrrE is involved in upregulation of DNA repair and other genes has remained unknown for many years. We have now demonstrated that IrrE is a metalloprotease that cleaves and inactivates repressor protein DdrO (2). In *D. deserti*, this cleavage is stimulated by irradiation.

**NEXT GENERATION SEQUENCING FOR THE IDENTIFICATION OF  
FILAMENTOUS BACTERIA IN INDUSTRIAL ACTIVATED SLUDGE PLANTS**

*M. Denecke*<sup>1</sup>, *T. Dunkel*<sup>1</sup>, *E. de Leon Gallegos*<sup>1</sup>, *C. Bock*<sup>1</sup>, *A. Goldbach*<sup>1</sup>, *J. Boenigk*<sup>1</sup>,  
*D. Hoffmann*<sup>1</sup>

<sup>1</sup>*Civil Engineering, University of Duisburg-Essen, Essen, Germany*

**Background**

Filamentous bacteria are mostly identified in activated sludge. Under specific conditions these organisms can outcompete other bacteria inducing process disturbances underlining the importance of a better comprehension and understanding on the growth of these bacteria to develop effective control measures.

**Objectives**

Identification of filamentous bacteria present in industrial WWTPs and evaluation of influencing factors on the growth of these bacteria.

**Methods**

Activated sludge samples from two industrial WWTPs in Germany were collected.

DNA-sequencing based PCR-product from all bacteria primer (104F, 515R) was conducted via Illumina platform.

Sequencing data was generated using a developed bioinformatics pipeline and it was further analyzed by BLAST.

Biodiversity analyses using MEGA 5.1 and R studio 3.1.0 were performed.

**Conclusions**

In total 432 different gene sequences were identified showing 17 sequences related to bulking and foaming bacteria as described in Guo and Zhang (2012).

The abundance of filamentous bacteria was calculated as the percentage of total reads. *Chryseobacterium* sp. *Iso-52* (24.82 %), *Candidatus Microthrix parvicella* (*M. parvicella*) clone OTU-5-40m.ABB (21.77 %), *Chloroflexi bacterium* ET1 (15.61 %) and *Gordonia* sp. YIM 100324 (11.67 %) were the most dominant filamentous organisms found.

Phylogenetic analysis revealed a close relationship of *M. parvicella* and *Gordonia*.

Canonical correspondence analysis (CCA) indicated positive correlations to sludge age and wastewater influent for *M. parvicella* and *Gordonia*, while dissolved oxygen (DO), effluent phosphorous and ammonia concentration, nitrate sludge loading showed a negative impact. It was also observed that the occurrence of *M. parvicella* and *Gordonia* is connected to high sludge volume index (SVI) and floating sludge

fraction (AVA) values.

## **SURVIVAL OF VIABLE LISTERIA MONOCYTOGENES CELLS DURING LIVESTOCK MANURE STORAGE DETERMINED BY MOLECULAR AND CULTURE ASSAYS**

J. Desneux<sup>1</sup>, A. Biscuit<sup>1</sup>, S. Picard<sup>1</sup>, A.M. Pourcher<sup>1</sup>

<sup>1</sup>GERE, IRSTEA, Rennes, France

### **Background**

Pig manure is usually stored in pits before spreading on agricultural land. It may also be biologically treated, leading to a liquid fraction stored in a lagoon (lagoon effluent). The impact of the storage on the persistence of pathogens depends on environmental factors and on intrinsic factors of the pathogens including their ability to enter into a viable but non cultivable (VBNC) state.

### **Objectives**

This study aims to compare the behaviour of *Listeria monocytogenes* which can enter VBNC state, in pig manure and in lagoon microcosms.

### **Methods**

Two strains of *L. monocytogenes* belonging to different serogroups were isolated from two farms. They were inoculated in flasks containing two manures and two lagoon effluents stored at 8 and 20°C during 63 days. The bacteria were quantified by cultural method, qPCR and qPCR associated with Propidium MonoAzide which quantifies both cultural and VBNC cells.

### **Conclusions**

Regardless their origin and their serogroup, both strains showed similar kinetics of decrease. The lower temperature increased the persistence of the strains. An effect of the matrix was observed not only between manures and lagoon effluents but also within a same type of matrix with similar chemical composition, suggesting that biotic factors may play a role in the persistence of *L. monocytogenes*. The VBNC appeared within the first hours of contact regardless the matrix. Nevertheless, their proportion increased over time in the effluent lagoon.

This study highlights that lagoon effluents used for watering plants, creates more favorable conditions than manure for VBNC cells of *L. monocytogenes*.

**Environmental microbiology**

## **DENITRIFICATION AND NITROUS OXIDE PRODUCTION IN SOILS IN THE HAMPSHIRE RIVER AVON CATCHMENT IN THE UNITED KINGDOM**

L. Dong<sup>1</sup>, D. Nedwell<sup>1</sup>, G. Underwood<sup>1</sup>, C. Whitby<sup>1</sup>, A. Stott<sup>2</sup>

<sup>1</sup>*School of Biological Sciences, University of Essex, Colchester, United Kingdom*

<sup>2</sup>*Centre for Ecology and Hydrology, Life Sciences Mass Spectrometry Facility, Lancaster, United Kingdom*

### **Background**

Microbial denitrification can lead to a loss of N from soils to atmosphere as N<sub>2</sub> or N<sub>2</sub>O. However, the magnitude of the soil N sink and environmental factors regulating denitrification are essentially unknown in UK catchments.

### **Objectives**

This study aims to examine seasonal and spatial variation of denitrification and N<sub>2</sub>O production and environmental factors regulating the processes and constrained the magnitude of N loss by denitrification.

### **Methods**

Rates of denitrification and N<sub>2</sub>O production were measured in the laboratory by <sup>15</sup>N isotope enrichment technique in grassland soils in three sub-catchments with contrasting geologies (clay, greensand and chalk) in the River Avon catchment at four seasons from August 2013 to May 2014,

### **Conclusions**

Denitrification and N<sub>2</sub>O production varied seasonally and spatially with annual mean rates of denitrification of 0.025, 0.265, and 0.210 µg N.g<sup>-1</sup> dry soil.day<sup>-1</sup> respectively, and of N<sub>2</sub>O production of 0.870, 0.547 and 0.620 ng N.g<sup>-1</sup> dry soil.day<sup>-1</sup> respectively at clay, Greensand and chalk sites. Denitrification rates were higher in August and November and higher rates of N<sub>2</sub>O production were observed in August and May.

Rates of denitrification and N<sub>2</sub>O production, measured at four temperatures (4, 10, 20 and 30°C) and three levels of soil water concentration (57.5%, 77.5% and water saturation), increased with temperature and soil water content.

The dominating environmental factors for denitrification and N<sub>2</sub>O production were soil pH, soil water content and temperature. It is estimated that annual losses of N by

denitrification were 11.8, 125.8 and 99.7 kg N per hectare at clay, greensand and chalk sites respectively.

**EFFECT OF ENERGY CROP CULTIVATION AND FERTILIZATION ON SOIL  
ARCHAEAL COMMUNITY AND ITS POTENTIAL OF METHANOGENESIS IN  
ABANDONED PEAT EXTRACTION AREA**

M. Espenberg<sup>1</sup>, M. Truu<sup>1</sup>, J. Truu<sup>1</sup>, J. Järveoja<sup>1</sup>, M. Maddison<sup>1</sup>, H. Nõlvak<sup>1</sup>,  
U. Mander<sup>1</sup>

<sup>1</sup>Geography, Institute of Ecology and Earth Sciences, Tartu, Estonia

**Background**

Peat is an important resource and is being extracted widely from regions rich in peatlands, which inevitably leads to the problem of abandoned peatlands. These areas emit greenhouse gases (CH<sub>4</sub>, N<sub>2</sub>O, CO<sub>2</sub>) for decades if restoration action is not implemented. The potential of methane production of abandoned peatlands can be evaluated by the abundance of *mcrA* genes which encodes the alpha-subunit of the enzyme that catalyses the last step in CH<sub>4</sub> synthesis in all methanogens.

**Objectives**

The purpose of this study is to assess the effect of energy crop (*Phalaris arundinacea* L.) cultivation and fertilisation on the abundance of soil bacterial and archaeal 16S rRNA genes, and to evaluate the methanogenic potential of the microbial communities in the soils of the experimental plots on the abandoned peat extraction area.

**Methods**

The experiment was carried out in 2012-2014 and samples were collected from 12 experimental plots at the vegetation period. Besides the widely used statistical methods, linear mixed effects modelling was used to test relationships between gene parameter values and chemical variables and in cases of different grouping factors.

**Conclusions**

Various physicochemical parameters changed the abundance of peat methanogenic community in vertical profiles. Methane emission rates correlated with the abundance of peat deeper layers methanogenic community in uncultivated plots while without *Phalaris* cultivation there are less constraining factors. These findings are important in the assessment of global warming potential while using abandoned peat extraction areas to produce biomass for energy.

## **BIODECOLORIZATION OF INDUSTRIAL TEXTILE DYES BY A NEWLY ISOLATED BACILLUS SP.JG12 FROM TEXTILE EFFLUENTS**

J. Gami<sup>1</sup>, K. Vyas<sup>2</sup>

<sup>1</sup>*Department of Biosciences, Sauarashtra University Rajkot, Rajkot, India*

<sup>2</sup>*Department of Biosciences, Saurashtra University Rajkot, Rajkot, India*

### **Background**

Release of effluents from textile dyeing and printing industries prior to proper treatment is a vital source polluting water and soil. A number of structurally dissimilar industrial azo dyes are present in textile effluents.

### **Objectives**

To isolate, screen and characterize a bacterial isolate having potential to decolorize and degrade industrial textile dyes from textile effluent. To investigate the effects of various environmental and nutritional parameters on decolorization activity of that isolate on a specific dye under lab condition. To study phytotoxic effects caused by decolorized and degraded dye products.

### **Methods**

Decolorization and degradation study of selected dye was performed using UV Visible spectroscopy and HPLC analysis. Germination assay of seeds of some selected crops was performed to investigate the toxic effects of decolorized and degraded dye products,

### **Conclusions**

We were able to screen a bacterial isolate with decolorization and degradation potential from the textile effluents. The complete decolorization of dye (150 mgL<sup>-1</sup>) was achieved within 24 hrs of incubation under static culture condition (at pH7, 37°C). The maximum decolorization was found in presence of Yeast extract as a source of carbon (at pH7±0.2, 37°C) Static culture condition. Seeds irrigated with decolorized dye sample (under static culture condition) show inhibition in germination. Inhibition of seed germination was not observed in case of seeds irrigated using dye treated under sequentially static-shaking culture conditions did not show.

## **GENE CAPTURE BY HYBRIDIZATION AS A STRATEGY FOR TARGETED MICROBIAL GENOME RECONSTRUCTION**

C. Gasc<sup>1</sup>, C. Ribiere<sup>1</sup>, N. Parisot<sup>1</sup>, R. Beugnot<sup>1</sup>, C. Defois<sup>1</sup>, E. Peyretailade<sup>1</sup>, P. Peyret<sup>1</sup>

<sup>1</sup>Auvergne University, EA 4678 CIDAM, CLERMONT-FERRAND, France

### **Background**

Microbial communities show the greatest organisms diversity on earth. Culture-independent molecular approaches targeting ssu ribosomal RNA genes have revealed this extraordinary diversity. However, amplicons cannot establish the link between microbial communities structure and realized metabolic functions, limiting the comprehension of micro-organisms roles. Despite the advent of the current ultra-high throughput sequencing, efficient assembly of sequencing data from metagenomic samples remains difficult and complete genome reconstruction has been principally realized for dominant micro-organisms. Single cell sequencing strategies have also been developed to overcome these limitations and to access less abundant micro-organisms but are not always easily practicable.

### **Objectives**

Based on a solution hybrid selection method combined with next generation sequencing, we developed an innovative gene capture approach to enable the reconstruction of large genomic regions or even complete microbial genomes from complex environments.

### **Methods**

A first gene capture using highly specific short probes targeting 16S rRNA gene was applied on metagenomic DNA to obtain large specific probes (several kbp) spanning the biomarker and the unknown flanking regions of the microbial species of interest, *Roseobacter denitrificans*. Generated long probes were then used to capture very large DNA fragments of *R. denitrificans* within a mix of bacterial gDNA. Real-time PCR performed on captured DNA revealed a significant enrichment in targeted 16S rRNA gene, surrounding genes and even several Mbp away genes, suggesting the capture of *R. denitrificans* complete chromosome.

### **Conclusions**

Sequencing of captured DNA allows identification of unknown sequences and reveals new genetic associations. This promising approach will facilitate linking identity and associated functions.

**Environmental microbiology**

**THE IMPACT OF SEPTIC SYSTEMS AND WATERSHED LEVEL CHARACTERISTICS ON STREAM FAECAL POLLUTION IN SUBURBAN WATERSHEDS IN GEORGIA, USA**

M. Habteselassie<sup>1</sup>, R. Sowah<sup>1</sup>

<sup>1</sup>*Crop and Soil Sciences, University of Georgia Griffin Campus, Griffin, USA*

**Background**

A quarter of housing units in the USA use septic systems for wastewater treatment and disposal. As widely as septic systems are used, their watershed level impact on water quality is poorly understood.

**Objectives**

The objective of this study was to determine the impact of septic systems on water quality and in so doing identify watershed level characteristics that influence their impact.

**Methods**

Water samples, collected from 24 well characterized watersheds with varying septic density, were analyzed for fecal indicator bacteria to quantify pollution levels and identify seasonal trends. The watersheds represent a gradient of land-use conditions from low to high density of septic systems, as well as developed to undeveloped uses. Pollutant sources were then tracked using *Bacteroides* sp. genetic markers.

**Conclusions**

Our findings indicated statistically significant interaction between septic density and season for enterococci count ( $P = 0.005$ ) and stream yield ( $P = 0.04$ ). Seasonal variations in bacterial count and stream yield were also observed, with significant differences between spring–winter and summer–winter. Multiple linear regression models suggested that 4 watershed characteristics (septic density, median distance of septic systems to stream, % developed area and forest cover) and water temperature could explain about half of the variability in bacterial count and yield in spring and summer. There was a significantly positive correlation ( $R = 0.67$ ) between septic density above 77 units/km<sup>2</sup> and human-specific marker yield (indicator of septic contribution). Overall study conclusion was that septic density strongly influences fecal pollution but its impact is dependent on season and watershed characteristics.

**ANAEROBIC DEHALOGENATING BACTERIA RELATED TO DESULFOLUNA SPONGIIPHILA FORM A COSMOPOLITAN GROUP WIDELY DISTRIBUTED IN ORGANOHALIDE-CONTAINING SPONGES**

M. Häggblom<sup>1</sup>, I. Horna-Gray<sup>1</sup>, N. Lopez-Chiaffarelli<sup>1</sup>, J. Liu<sup>1</sup>, Y.B. Ahn<sup>1</sup>, L.J. Kerkhof<sup>2</sup>

<sup>1</sup>Biochemistry and Microbiology, Rutgers The State University of New Jersey, New Brunswick, USA

<sup>2</sup>Marine and Coastal Sciences, Rutgers The State University of New Jersey, New Brunswick, USA

**Background**

The marine environment is a rich source of biogenic organohalides produced by a diversity of marine organisms, such as sponges that produce a vast array of halogenated bioactive compounds as secondary metabolites. These organohalogen compounds in turn appear to select for bacteria that can utilize them as a source of energy.

**Objectives**

Our objectives are to investigate the dehalogenating bacterial populations within the sponge animal with the overall goal of understanding the roles and metabolic activities of this endomesohyl microbiota.

**Methods**

We enriched for bromophenol dehalogenating bacterial symbionts from a range of sponge species collected at different sites in the Mediterranean, Atlantic and Pacific, and applied an integrated cultivation and molecular analysis-based approach to analyze the bacterial communities.

**Conclusions**

We demonstrated the widespread distribution of anaerobic reductive debrominating bacteria in different marine sponges. We isolated a novel bacterial species, *Desulfoluna spongiiphila*, from Mediterranean sponges that grows by respiratory reductive dehalogenation. Using a cultivation and molecular analysis-based approach we demonstrated that *D. spongiiphila* and its close relatives form a cosmopolitan group widely distributed in organohalide-containing sponges across different geographic locations. The sponge-associated dehalogenating bacteria can operate *in vivo* and impact the fate of brominated organics. This new bacterial species group is an excellent model system to study a 'chemically-driven' endosymbiotic relationship and one possible origin of organohalogen respiration. Organobromine-rich sponges

appear to provide a specialized, possibly ancient, habitat for organohalide-respiring microbes, which mediate a cycling of organohalide compounds within the sponge animal.

**FEMS-0616**

**Environmental microbiology**

## **METHANESULFONATE (MSA) CATABOLIC GENES FROM MARINE AND ESTUARINE BACTERIA**

A. Henriques<sup>1</sup>, P. De Marco<sup>1</sup>

<sup>1</sup>*Microbial Ecology, CESPU IINFACTS, Paredes, Portugal*

### **Background**

Quantitatively methanesulfonate (MSA) is very relevant in the global biogeochemical sulfur cycle. MSA utilization by bacteria as a source of carbon and energy has been described and a specific enzyme, methanesulfonate monooxygenase (MSAMO), has been found to perform the first catabolic step of its oxidation. Other proteins, seemingly involved in the import of MSA into bacterial cells, have been reported.

### **Objectives**

In this work we looked for the genes encoding the large subunit of the MSAMO (*msmA*) and the periplasmic component of the import system (*msmE*) in the genomes of MSA-enriched bacteria and also in metagenomic DNA from seawater, in order to extend our knowledge on these genes as ecofunctional genetic markers of MSA degradation.

### **Methods**

PCR approaches were implemented and the resulting products were cloned and sequenced. Two novel marine MSA-isolates were also submitted to whole genome sequencing.

### **Conclusions**

In conclusion, novel *msmA* and *msmE* sequences were obtained, and two full *msm* operons were found in the genomes of the novel marine strains. Clearly, the *msmA* genes (and derived proteins) show less sequence variability than *msmE*. This, added to the apparent conservation of a peculiarly long Rieske-associated motif, reinforces the value of *msmA* as ecofunctional indicator for methanesulfonate cycling by bacterial natural communities. In the line of previous observations, our results also show that high-GC strains are somehow favoured during enrichment and isolation of MSA-utilizing bacteria, illustrating the misrepresentation of natural populations that

culturing may entail.

**Environmental microbiology**

**BIOREMEDIATION: A TOOL OF MULTIPLE HEAVY METALS RESISTANT  
ENDOPHYTIC FUNGI FOR PHYTOSTIMULATION**

A. Hussain<sup>1</sup>, M. Zahoor<sup>1</sup>

<sup>1</sup>Botany, Abdul Wali Khan University, Mardan, Pakistan

**Background**

Heavy metal pollution is of great concern in countries like Pakistan where a huge proportion of human population is exposed to it. Bioremediation is one of the most viable and efficient solution for the problem.

**Objectives**

Purpose of the current study was to isolate endophytic fungi from corn plants and screen them for phytostimulation under heavy metal stress.

**Methods**

Endophytic strain (MHR-23) was identified as *Paecilomyces formosus* by 28 S rDNA and internal transcribed spacer (ITS) sequence homology. The strain effectively tolerated up to 2000 µg mL<sup>-1</sup> of these heavy metals. Adverse effects of metals were obvious in the form of gradual decrease of fungal growth by increasing the concentration of heavy metals. The strain was able to remove 60-87 % of metals (300 µg mL<sup>-1</sup>) from PDA broth. The strain removed metals by biotransformation and/or accumulation of heavy metal in its hyphae. Growth of corn stressed with heavy metals was restored by the application of MHR-23. Accumulation of heavy metals by corn stem and leaves was significantly reduced ( $p < 0.05$ ) by the application of MHR-23.

**Conclusions**

It may be concluded that MHR-23 is an excellent candidate to be used as biofertilizer in fields affected with heavy metals.

**Environmental microbiology**

**GENOME DATA MINING IN DETERMINATION OF GENES INVOLVED IN THE ANTIMICROBIAL ACTIVITY OF PSEUDOMONAS SP. P482 AGAINST PLANT PATHOGENIC BACTERIA AND FUNGI**

*D. Krzyzanowska<sup>1</sup>, M. Rajewska<sup>1</sup>, M. Jabłońska<sup>1</sup>, S. Jafra<sup>1</sup>*

*<sup>1</sup>Department of Biotechnology, Intercollegiate Faculty of Biotechnology UG-MUG, Gdansk, Poland*

**Background**

To survive in a competitive environment, the plant-associated *Pseudomonads* produce a set of biologically active compounds, many of them known for their antimicrobial properties. *Pseudomonas* sp. P482, a tomato rhizosphere isolate, shows antagonistic activity towards a spectrum of plant pathogenic bacteria and fungi.

**Objectives**

In this study, we aimed to apply a genome data mining approach to determine the genetic background of the antibacterial activity of the P482 strain.

**Methods**

The genome sequencing of P482 was performed. Bioinformatics tools such as the antiSMASH and BAGEL3 were employed to analyze the resulting data and to determine the 'candidate' genes potentially involved in the antimicrobial activity of the P482. The 'candidate' genes were subjected to site directed mutagenesis with the use of a suicide vector. The obtained mutants were tested for the lack of antimicrobial activity towards selected strains of plant pathogenic bacteria and fungi.

**Conclusions**

A draft genome sequence of P482 was obtained and automatically annotated. The BAGEL3 analysis yielded no putative bacteriocins. The antiSMASH analysis revealed 5 biosynthetic clusters encoding biosynthetic genes potentially involved in the synthesis of antimicrobial factors. Knock out of the 5 major biosynthetic genes, one per each predicted cluster, has shown that these genes are not essential for the antimicrobial activity of P482 against the soft rot bacteria. Thus, genome mining is a powerful approach yet when novel mechanism of antagonism are at stake, as in seems to be in case of the P482, it should be used in combination with alternative methods.

**ELUCIDATING THE GENETIC BASIS FOR SULFONAMIDE DEGRADATION IN ISOLATES WITH DIVERSE PHYLOGENETIC BACKGROUND**

B.A. Kolvenbach<sup>1</sup>, B. Ricken<sup>1</sup>, A.C. Reis<sup>2</sup>, O.C. Nunes<sup>2</sup>, C.M. Manaia<sup>3</sup>, H. Strnad<sup>4</sup>, C. Vlcek<sup>4</sup>, P.F.X. Corvini<sup>1</sup>

<sup>1</sup>*School of Life Sciences,*

*University of Applied Sciences and Arts Northwestern Switzerland - FHNW, Muttens, Switzerland*

<sup>2</sup>*Universidade do Porto, LEPAE Faculdade de Engenharia, Porto, Portugal*

<sup>3</sup>*Universidade Católica Portuguesa, Centro de Biotecnologia e Química Fina, Porto, Portugal*

<sup>4</sup>*Genomics and Bioinformatics, Institute of Molecular Genetics of the ASCR, Prague, Czech Republic*

**Background**

Sulfonamides antibiotics are among the most frequently prescribed antibiotics in human and veterinary medicine, and, at the same time quite recalcitrant to degradation. Therefore, sulfonamides can be commonly detected in wastewater worldwide in trace amounts. Up to now, few sulfonamide degrading bacteria stemming from different phyla have been isolated. While the degradation mechanisms in most strains have not been conclusively elucidated yet, most cases were shown to lead to analogous metabolites

**Objectives**

The intention of this study is to understand how sulfonamide degradation genes are propagated in the environment and whether the isolated sulfonamide strains have in common a similar apparatus of genes encoding degradative enzymes.

**Methods**

A set of draft genomes of sulfonamide degrading bacteria was obtained by next generation sequencing of genomic DNA of these strains and from public available data sets. The nucleotide sequence of a gene cluster related to sulfonamide degradation in *Microbacterium* sp. BR1 was compared to similar regions found in other strains.

**Conclusions**

It was found that some sulfonamide degraders contained in their genome DNA regions highly similar to that found to be responsible for degradation in *Microbacterium* sp. strain BR1, while for others, similarities to this region were too low to safely attribute the same function to the encoded enzymes. It remains to be solved

whether these distantly related genes confer degrading activity in these strains or whether completely different enzymes are involved.

**FEMS-1487**

**Environmental microbiology**

## **ROLE OF VIBRIO CHOLERAE ADHESINS IN SURVIVAL OF PREDATION BY HETEROTROPHIC PROTISTS**

D. McDougald<sup>1</sup>, S. Sun<sup>1</sup>

<sup>1</sup>Centre for Marine Bio-Innovation, University of New South Wales, Sydney, Australia

### **Background**

*Vibrio cholerae* is an opportunistic pathogen and a natural inhabitant of aquatic ecosystems. Predation by heterotrophic protozoa has a major impact on the environmental survival of *V. cholerae*. Adhesins are important virulence factors required for *V. cholerae* pathogenesis but may have evolved during long-term interactions with protozoa.

### **Objectives**

Here, we investigated the role of *V. cholerae* adhesions (TcpA, MshA, GbpA, LapA and VC1804) in resistance to predation by the surface-feeding *Acanthamoeba castellanii*.

### **Methods**

*V. cholerae* wild type stains and adhesin mutants were exposed to predation by *A. castellanii*. The grazing resistance was determined by *V. cholerae* selective grazing assays, and quantification of *V. cholerae* cells attached to the surface and/or internalized by *A. castellanii* as assessed by CFUs and microscopy.

### **Conclusions**

Data show that only VC1804 made a significant contribution to grazing resistance as the mutant was grazed more than the parent wild type. Compared to wild type strains, the MshA and VC1804 mutants exhibited significantly lower colonization efficiency for the *A. castellanii* surface, which also resulted in less cells surviving intracellularly in the amoebae. These findings further elucidate the role of *V. cholerae* adhesins in persistence in the environment and support the hypothesis that some virulence factors provide for increased fitness in the environment.

**Environmental microbiology**

## **THE VALUE OF *P. AERUGINOSA* IN HEALTH AND MICROBIOLOGICAL QUALITY CONTROL OF RECREATIONAL WATERS USING IN PUBLIC SWIMMING POOLS**

M. Hajjartabar<sup>1</sup>, T. Kermani Ranjbar<sup>1</sup>

<sup>1</sup>Basic Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran

### **Background**

*Pseudomonas aeruginosa* is the most significant bacteria capable of multiplying in water especially in recreational waters. Nowadays most public swimming pools use recreational water.

### **Objectives**

To assess if these swimming pools are health risk to users, eleven of public swimming pools in East and North-East of Tehran were monitored. Useful information such as flow rate of filtration of water in the pools, clarity, temperature and pH of the water were recorded at the same time of sampling too.

### **Methods**

According to the Standard Method 21th edition, Bacteriological tests such as isolation, identification and colony counts of *Escherichia coli*, coliforms, and *Pseudomonas aeruginosa* were performed on the samples. *P. aeruginosa* was isolated from 9(81.8%) of the pools. Also *P. aeruginosa* was the only predominant organism isolated from 7(63.6%) of the pools, while in the remained 2(18.2%) other, in addition to *P. aeruginosa*, high rates of total bacterial count, total coliforms and faecal coliform counts were also found.

### **Conclusions**

Results of the contaminated swimming pools revealed that chlorination was often inadequate to disinfect mentioned bacteria especially *P. aeruginosa* when high population of people had to over use of the pools. Thus results of this study, showed the importance and the value of assaying presence of indicator of *P. aeruginosa* routinely in quality control of recreational waters using in public swimming pools.

<sup>2</sup>*Biogeochemistry, Helmholtz-Center for Ocean Research, Kiel, Germany*

**Background**

Symbioses between phytoplankton and N<sub>2</sub>-fixing microorganisms play a pivotal role in the ocean's carbon and nitrogen cycle. The abundant and widespread unicellular cyanobacteria group A (UCYN-A) was recently found to live symbiotically with a haptophyte.

**Objectives**

Here, we investigated the effect of nitrogen (N), phosphorus (P), iron (Fe) and Saharan dust additions on nitrogen (N<sub>2</sub>) fixation and primary production by the UCYN-A-haptophyte association in the subtropical eastern North Atlantic Ocean.

**Methods**

In order to determine single-cell rates of N<sub>2</sub> fixation and primary productivity, we used stable isotope incubations combined with nanoSIMS measurements. *nifH* gene expression analysis was carried out to determine the molecular regulation of N<sub>2</sub> fixation under the different nutrient conditions.

**Conclusions**

N<sub>2</sub> fixation by UCYN-A was stimulated by the addition of Fe and Saharan dust whereas CO<sub>2</sub> fixation by the haptophyte was stimulated by the addition of ammonium nitrate as well as Fe and Saharan dust. However, there were no detectable differences in *nifH* gene expression in any of the incubations. Independent of the nutrient treatment, we observed a mutual exchange of carbon and nitrogen between the UCYN-A and the haptophyte suggesting a tight coupling. However, it appears that the transfer of carbon from the haptophyte to UCYN-A requires a transfer of nitrogen from UCYN-A indicating an obligate symbiosis of this globally important diazotrophic association.

<sup>7</sup>Waste & Environmental Geochemistry, NNL, Warrington, United Kingdom

<sup>8</sup>The safety of a deep geologic repository, FANC, Brussels, Belgium

<sup>9</sup>research geological disposal, AECL, Manitoba, Canada

**Background**

Clay deposits such as the Opalinus Clay formation are studied as host rocks for geological disposal of high- and intermediate-level long-lived radioactive waste in several European countries. Bituminized intermediate-level long-lived radioactive waste contains, besides bitumen and radionuclides, also large amounts of organics, nitrates and sulphates. Over time, these salts will dissolve, leach and diffuse into the surrounding clay host rock, together with water soluble organic substances. To mimic the potential effect of such inorganic– and organic leachates, pulses of nitrate and/or acetate have been injected in intervals of an *in situ* experiment, called Bitumen-Nitrate-Clay interaction (BN) experiment, running at the Mont Terri geological laboratory (St. Ursanne, Switzerland).

**Objectives**

To elucidate whether the microbial communities, present in the BN experiment, are affected or involved in the observed biogeochemical changes.

**Methods**

Beside classical microbial analyses, at pivotal moments (*i.e.* before, during and after these pulse injection tests), priority was given to DNA-based molecular biology analysis methods, as these methods provide very accurate information on the composition, the metabolic capacity and possible evolution of bacterial communities in response to the nitrate and/or acetate injections.

**Conclusions**

The changes observed in the bacterial populations appeared to correlate well with the imposed physico-chemical changes. As soon as nitrate was added an overwhelming community shift appeared to nitrate reducing bacteria. If in parallel acetate was offered, the community composition did not alter that much, but the speed of nitrate reduction was increased twentyfold. This high nitrate removal speed was maintained as long as the easily consumable carbon source was abundant.

**FUNCTIONAL CHARACTERIZATION OF METAGENOMES FROM MICROBIAL COMMUNITIES IN PRISTINE AND CHRONICALLY-POLLUTED HARBOR WATERS IN RELATION TO HYDROCARBON POLLUTION**

B. Nogales<sup>1</sup>, C.M. Alejandro-Marín<sup>1</sup>, R. Bosch<sup>1</sup>

<sup>1</sup>Biology, University of the Balearic Islands, Palma de Mallorca, Spain

**Background**

The phylogenetic composition of bacterial communities in chronically-polluted harbor waters in Mallorca Island (Spain) has been shown to differ from those in nearby clean waters, with a characteristic predominance of bacteria from the Roseobacter clade (Nogales *et al.*, 2007). We have also observed that bacteria of this group proliferate after artificial pollution with diesel oil (Lanfranconi *et al.* 2010).

**Objectives**

Given these facts, and the evidences relating roseobacters with aromatic hydrocarbon degradation, our aim was to explore the functional diversity of bacteria in polluted harbor waters and waters polluted artificially, with special attention to genes for the catabolism of hydrocarbons, and relate it with the presence of members of the Roseobacter clade.

**Methods**

Eight metagenomes have been generated (20.6 Gb in total) using Illumina technology. Sequences filtered using quality criteria are analyzed using MG-Rast (Meyer *et al.*, 2008), and in house assembly and annotation.

**Conclusions**

Phylogenetic affiliation of sequence reads confirmed the abundance of roseobacters in the metagenomes from polluted samples. Genes coding for peripheral and central pathways for aromatic hydrocarbon degradation have been observed in all metagenomes analyzed. However, at a broad level of resolution we cannot evidence significant differences in number of reads between metagenomes from polluted and control samples. Recruitment of sequence reads against protein databases from Roseobacter genomes and for catabolism of hydrocarbons would help us to define the fine catabolic differences between polluted and unpolluted samples.

## **BIOFLOCCULANT PRODUCTION BY ACTINOBACTERIA CONSORTIA AND MEDIA OPTIMIZATION THROUGH RESPONSE SURFACE MODEL**

U.U. Nwodo<sup>1</sup>, S.C. Udem<sup>2</sup>, L.V. Mabinya<sup>1</sup>, A.I. Okoh<sup>1</sup>

<sup>1</sup>Biochemistry and Microbiology, University of Fort Hare, Alice, South Africa

<sup>2</sup>Veterinary Physiology and Pharmacology, University of Nigeria Nsukka, Nsukka, Nigeria

### **Background**

Flocculants aggregates suspended particles in solutions thus, reducing turbidity. The industrial application of this process includes water/wastewater treatment.

Conventionally used flocculants have been implicated in deleterious health problems hence, the need for a safe alternative. Bioflocculants are valuable alternative as they are non-toxic and biodegradable.

### **Objectives**

The consortia of *Brachybacterium*, *Cellulomonas* and *Streptomyces* were evaluated for bioflocculant production and their nutritional requirements optimized via response surface model.

### **Methods**

*Cellulomonas*, *Streptomyces* and *Brachybacterium* species were evaluated in pair wise consortium for enhanced production of bioflocculant. Bioflocculant production, flocculation activity testing and media optimization through response surface model were in accordance with standard methods.

### **Conclusions**

Nutritional preferences for bioflocculant production were; glucose (56%;  $2.78 \pm 0.15$  g/l),  $(\text{NH}_4)_2\text{NO}_3$  (53%;  $2.81 \pm 0.37$  g/l) and  $\text{CaSO}_4 \cdot \text{H}_2\text{O}$  (47%;  $2.19 \pm 0.13$  g/l) against *Brachybacterium* and *Streptomyces* species, glucose (92%;  $4.06 \pm 0.62$  g/l), peptone (89%;  $3.88 \pm 0.432$  g/l) and  $\text{MgCl}_2$  (83%;  $3.99 \pm 0.79$  g/l) against *Cellulomonas* and *Brachybacterium* species. Lastly, sucrose (91%;  $4.01 \pm 0.22$  g/L), peptone (82%;  $3.21 \pm 0.13$  g/L) and magnesium chloride (78%;  $3.29 \pm 0.42$  g/L) were preferred by the consortium of *Streptomyces* and *Cellulomonas* species. Plackett-Burman design revealed that the carbon, nitrogen and cation sources were the critical media components essential for the production of bioflocculant. High regression coefficients respectively obtained for the consortia was indicative of the model adequacy ( $P \leq 0.05$ ). The bioflocculant compositional analysis and functional group determination (FTIR spectrometry) indicates a heteropolysaccharides bioflocculant while SEM imaging revealed an amorphous loosely arranged fluffy structure with interstice less than  $1\mu\text{m}$ . The high flocculation activity shown suggests suitability for industrial processes.

**THE INFLUENCE OF AI-2 MOLECULES ON RHAMNOLIPIDS SECRETION  
EXHIBITED BY PSEUDOMONAS AERUGINOSA WITHIN MICROBIAL  
COMMUNITY**

A. Parus<sup>1</sup>, M. Wozniak<sup>1</sup>, A. Szulc<sup>1</sup>, M. Sydow<sup>1</sup>, P. Lisiecki<sup>1</sup>, L. Lawniczak<sup>1</sup>,  
L. Chrzanowski<sup>1</sup>

<sup>1</sup>Institute Chemical Technology and Engineering, Poznan University of Technology,  
Poznan, Poland

**Background**

Rhamnolipids are a group of biosurfactants produced by *Pseudomonas* species. It was proven that rhamnolipids participate in biofilm formation and play an important role in microbial motility. Because of their biodegradability and biocompatibility, they are also considered as promising alternatives to widely used synthetic agents in surfactant-mediated bioaugmentation. The cooperation and competition between indigenous and exogenous microorganisms plays an essential role in the final bioaugmentation effect and is based on quorum sensing (QS) mechanism, which enables cell to cell communication. The autoinducers 2 (AI-2) are QS signal molecules observed in both Gram-positive and Gram-negative bacteria. We hypothesize that AI-2 molecules play important role in secretion of rhamnolipids by *Pseudomonas aeruginosa* within microbial community.

**Objectives**

1. To isolate biosurfactant-produced bacteria and investigate the structures of secreted compounds.
2. To investigate the relationship between AI-2 activity and secretion of rhamnolipids.

**Methods**

Isolation: samples originating from cow, chicken and pig feces; screening of bacterial communities by: (i) oil spreading, (ii) drop collapse, (iii) hemolytic activity, (iv) emulsification activity; bioreactor cultivation: Sartorius Stedim, Germany; surface tension: Krüss, Germany; bioluminescence assay: *Vibrio harveyi* BB170 and *Vibrio harveyi* BB152; rhamnolipids identification: HPLC-MS.

## Conclusions

Only monorhamnolipids were detected in the consortium and *Pseudomonas aeruginosa* supernatants. The maximal rhamnolipids production by *Pseudomonas aeruginosa* and AI-2 activity were observed at the same time. The results indicate that QS molecules secreted by associated microorganisms have significant influence on *Pseudomonas aeruginosa* gene expression responsible for rhamnolipids production.

**Environmental microbiology**

**THE INFLUENCE OF ZEROVALENT IRON ON THE DEGRADATION OF  
HEXABROMOCYCLODODECANE BY MICROCOSM FROM RIVER SEDIMENT**

Y.H. Peng<sup>1</sup>, Y.J. Chen<sup>1</sup>, Y.h. Shih<sup>1</sup>

<sup>1</sup>*Department of Agriculture Chemistry, National Taiwan University, Taipei, Taiwan*

**Background**

Brominated flame retardants (BFRs) have been widely used in many industries over decades. Hexabromocyclododecane (HBCD) is one of the most commonly used BFRs, but it has just listed on the table of persistent organic pollutants (POPs).

**Objectives**

In order to develop cost-effective remediation methods for this emerging pollutant, we evaluated the HBCD degradation ability of one anaerobic microcosm from river sediment, as well as the influence of zerovalent iron (MZVI) on the biodegradation.

**Methods**

An anaerobic sediment sample was acclimated by HBCD. The supernatant solution which contained microcosm was used to conduct further experiments. MZVI (2.5 g L<sup>-1</sup>) was used to degrade HBCD alone or together with the microcosm.

**Conclusions**

The microcosm started to degrade HBCD at day 7, and 30% of HBCD was eliminated in the following 4 days. Sixty percent of HBCD was degraded by MZVI or the co-incubated system after 11 days of incubation. The HBCD biodegradation ability was inhibited by MZVI. MZVI degraded HBCD through reductive debromination, however, this reaction did not occur in the biodegradation setting, suggesting that the microcosm eliminated HBCD through other mechanism. The fluctuation of bacterial community during the degradation processes was monitored. Cluster analysis shown that the microbial composition was less close to that of the MZVI added ones. The inhibition of biodegradation from MZVI may due to the alteration of medium characteristics, which in term changed the microbial composition and function. Our studies provided an insight into the influence of MZVI on the biodegradation of HBCD, which would facilitate the bioremediation of BFRs.

## **BACTERIA ISOLATED FROM DIATOM BLOOMS SEA WATER ADAPT AND GROW IN THE PRESENCE OF POLYUNSATURATED ALDEHYDES**

M. Pepi<sup>1</sup>, H.J. Heipieper<sup>2</sup>, R. Casotti<sup>1</sup>

<sup>1</sup>*Integrative Marine Ecology, Stazione Zoologica Anton Dohrn, Naples, Italy*

<sup>2</sup>*Environmental Biotechnology, Helmholtz Centre for Environmental Research UFZ, Leipzig, Germany*

### **Background**

Diatoms commonly grow in association with heterotrophic bacteria (Amin et al., 2012) and some species produce polyunsaturated aldehydes (PUAs), which antimicrobial activity (Ianora et al., 2004). Therefore, diatom-associated bacteria may have evolved resistance to PUAs (Ribalet et al., 2008; Balestra et al., 2011), possibly involving adaptive mechanisms of membrane fatty acids (Heipieper and de Bont, 1994; Heipieper et al., 2007).

### **Objectives**

The objectives of this study were the isolation of PUAs-resistant bacterial strains from sea water during diatom blooms and the investigation of bacterial adaptive mechanisms to PUAs.

### **Methods**

Enrichment cultures in mineral medium with PUAs (2*E*,4*E*/*Z*-heptadienal, 2*E*,4*E*/*Z*-octadienal, 2*E*,4*E*/*Z*-decadienal) were inoculated with sea water and incubated at 22°C. PUA-resistant bacteria were isolated, identified by 16S rDNA, grown in the presence of the PUAs and analyzed at membrane fatty acids level.

### **Conclusions**

Six PUAs-resistant isolates, i.e. 1A, 5a, 5b, 7a, 11 and 12b, were assigned to the genera *Pseudomonas*, *Sufflavibacter*, *Halomonas*, *Vibrio*, *Idiomarina* and *Labrenzia*, respectively. Strains 1A, 5b and 7a showed higher growth in the presence of PUAs with respect to the others. Preliminary data on adaptive responses to the PUAs on membrane fatty acid level revealed an increased saturation.

**INVESTIGATION OF BIOTIC AND ABIOTIC FACTORS THAT AFFECT SURVIVAL OF THE PATHOGENIC BACTERIUM *LISTERIA MONOCYTOGENES* IN SOIL**

A.L. Vivant<sup>1</sup>, D. Garmyn<sup>1</sup>, A. Locatelli<sup>1</sup>, L. Gal<sup>1</sup>, A. Spor<sup>1</sup>, P.A. Maron<sup>1</sup>, A. Hartmann<sup>1</sup>,  
P. Piveteau<sup>1</sup>

<sup>1</sup>Agroécologie, UMR Agroécologie 1347, Dijon, France

**Background**

Agroecosystems are dedicated to the provision of high quality, safe food and sustainability is a major issue. Biological contamination of the food supply raises food safety issues. Prevention of contamination of the food supply requires a thorough understanding of the ecology of pathogenic microorganisms. *Listeria monocytogenes* is a food pathogen found in many habitats including soil, plants, water systems and food processing factories.

**Objectives**

We designed microcosm experiments to decipher extrinsic factors that drive the fate of this model of Human pathogen in soil.

**Methods**

We analysed population dynamics over 80 days after inoculation of a set of 100 soil microcosms. Population dynamics in unsterilised and sterilised soil microcosms were compared. Detailed information such as soil characteristics and land use were integrated into an analysis of variance.

**Conclusions**

The population of *L. monocytogenes* decreased over time but survival depended on the soil under scrutiny. Chemical properties and soil texture affected survival of *L. monocytogenes*. The endogenous soil microbiota had a major impact on the decrease of the population of *L. monocytogenes*.

This prompted us to investigate the relationship between the biodiversity of the soil microbiota and the inhibition of the population of *L. monocytogenes*. We investigated the consequences of soil diversity erosion on the fate of a human bacterial pathogen in the telluric environment. Diversity analysis showed that both soil diversity and phylogenetic composition affected survival of *L. monocytogenes*.

Overall, our results demonstrate that soil biodiversity is a major driver that limit invasion of soil by pathogens.

## **BIOREMEDIATION OF WASTEWATER BY RHIZOBACTERIA AND THEIR APPLICATION IN ARTIFICIAL WETLANDS**

I. Salgado Bernal<sup>1</sup>, M. Cruz Arias<sup>1</sup>, M.E. Carballo Valdés<sup>1</sup>,

M.C. Durán Domínguez de Bazúa<sup>2</sup>

<sup>1</sup>Microbiology and Virology Department, Faculty of Biology. University of Havana, Havana, Cuba

<sup>2</sup>Environmental Chemistry and Engineering, Faculty of Chemistry. Mexican Autonomous National University Mexico, DF, Mexico

### **Background**

The treatment of wastewater, before their dumping to the aquatic ecosystems, constitutes a topic of current importance.

### **Objectives**

The objective of the research was to evaluate the physiologic and metabolic diversity of the rhizobacteria from hydrophyte plants of natural wetlands.

### **Methods**

Individual bacterial strains were tested in front of different pollutants. Microbial consortia were faced to water simulating a domestic effluent and synthetic water similar to an industrial effluent. This allowed the selection of the autochthonous strains *Bacillus* sp. (T-119, T-117 and T-229), *Acinetobacter* sp. (T-118), *Pseudomonas* sp. (T-1111) and *Exiguobacterium* sp. (T-316) for their capacities in the elimination of organic matter, ammonium and phosphate. Also, the strains *Bacillus* sp. (T-119, T-117, T-1115 and T-1113) were selected for the lead, chromium and mercury biosorption from synthetic residual waters. Two consortia designed with these strains achieved 75%, 85% and 100% removal of organic matter, ammonium and phosphate and 70%, 9% and 17% of lead, chromium and mercury, respectively. The effect of factors associated to the process of pollutants elimination was determined, which it contributed to the design and bioaugmentation with the consortia of artificial wetlands to laboratory scale. With these systems were reached 100%, over 70% and 55% removal of organic matter, ammonium and phosphate and elimination levels over 95%, 80% and 50% of lead, mercury and chromium, respectively.

### **Conclusions**

It was settled down an integral strategy for obtaining effective bacterial consortia in the bioaugmentation of constructed wetlands, applied in the removal of inorganic and organic pollutants.

## **ON THE EVOLUTION OF WRINKLY SPREADERS, WRINKLEALITY AND FITNESS**

*K. McLaughlin<sup>1</sup>, A. Spiers<sup>1</sup>*

<sup>1</sup>*SIMBIOS Centre, Abertay University, Dundee, United Kingdom*

### **Background**

Bacterial adaptive radiation has been extensively studied using *Pseudomonas fluorescens* SBW25 which gives rise to the Wrinkly Spreader (WS), a class of adaptive mutants producing a wrinkled colony morphology and air-liquid interface biofilms in static microcosms. The WS phenotype is the result of mutations targeting different diguanylate cyclases that up-regulate intracellular levels of c-di-GMP and induce biofilm-formation. Although variations in colony morphology have been noted previously, variations in the WS phenotype (wrinkleality) have not been quantified, nor related to the fitness advantage WS isolates have over other competitors in static microcosms.

### **Objectives**

In this work, we investigated the relationship between wrinkleality and fitness using WS isolates evolved in microcosms containing different growth media.

### **Methods**

Wrinkleality was quantified using a combined biofilm assay (measuring growth, biofilm strength and attachment levels), competitive fitness determined using the non-biofilm-forming reference strain SM-13, and data analyzed by ANOVA and fitness modeled using a GLM approach with environment (media) as the main factor and wrinklealities as covariates.

### **Conclusions**

Significant variation in wrinkleality and fitness was observed between and within WS isolates evolved in different environments. Environment, growth, strength and attachment were all found to have significant effects on fitness. This analyses has shown that growth media selected for subtly different classes of WS, and the underlying differences in phenotype could also help to explain the variation seen in fitnesses. These findings also provide evidence to suggest that WS mutations might have pleiotropic effects and explain why some Wrinkly Spreaders are more successful than others.

**ASSESSMENT OF MICROBIAL CONTAMINATION LEVEL OF SOLID WASTES FROM HOSPITALS IN UNIVERSITY OF PORT HARCOURT, NIGERIA.**

H. STANLEY<sup>1</sup>, H.O. STANLEY<sup>1</sup>, R. Enemugwem<sup>1</sup>

<sup>1</sup>MICROBIOLOGY, UNIVERSITY OF PORT HARCOURT, PORT HARCOURT, Nigeria

**Background**

Hospital solid waste disposal has become a major problem in that people indiscriminately dump this waste which pose health danger in the city and therefore there is need to assess these wastes in order to fully understand the micro organisms of health significance which could be transmitted through the improper disposal of these waste materials.

**Objectives**

This study was to evaluate the microbial load of solid health care waste from healthcare institutions in University of Port Harcourt. Solid waste samples were collected randomly from selected units from University of Port Harcourt teaching hospital and LULU Briggs health center

**Methods**

The method adopted was that of Faith Efosa Oviasogie *et al.*,(2010), modified.

**Conclusions**

Bacterial species isolated from the health care solid waste include; *Klebsiella*, *Pseudomonas*, *Staphylococcus*, *Proteus*, *Streptococcus* While *Klebsiella*, *Salmonella* and *Pseudomonas* were isolated from the control samples. The fungal species isolated from the health institutions of University of Port Harcourt include *Asprgillus* and *candida*, where-as *Candida* was isolated from the control sample. The total heterotrophic bacterial count from all samples collected ranged from  $1.8 \times 10^5$  to  $6.8 \times 10^8$  CfU/100g and total fungal count ranged from  $2 \times 10^2$  to  $7 \times 10^4$  CfU/100g. The predominant organisms were *Staphylococcus aureus*, *Klebsiella pneumonia* and *Pseudomonas aeruginosa*. Some of the bacterial isolates have been incriminated in nosocomial infections.

## **FRESHWATER ANAEROBIC OXIDATION OF METHANE ASSOCIATED WITH SULFATE REDUCTION IN A NATURAL GAS SOURCE**

*P. Timmers<sup>1</sup>, D.A. Suarez-Zuluaga<sup>2</sup>, M. van Rossem<sup>1</sup>, C.M. Plugge<sup>1</sup>, A.J.M. Stams<sup>1</sup>*

<sup>1</sup>*Laboratory of Microbiology, Wageningen University, Wageningen, Netherlands*

<sup>2</sup>*Sub-department of Environmental Technology, Wageningen University, Wageningen, Netherlands*

### **Background**

Anaerobic oxidation of methane (AOM) coupled to sulfate reduction (SR) occurs in marine sediments and the responsible microorganisms are communities of anaerobic methanotrophic archaea (ANME) and sulfate reducing bacteria (SRB) of the SEEP-SRB1 clade. AOM coupled to SR is rarely documented in terrestrial environments where sulfate concentrations are generally low.

### **Objectives**

The possible occurrence of AOM coupled to SR was investigated in a natural freshwater gas source. This was done to know where and if AOM coupled to SR occurs in terrestrial environments and which organisms execute this process.

### **Methods**

<sup>13</sup>CO<sub>2</sub> formation and methanogenesis was monitored at long term (>168 days) in slurries incubated with <sup>13</sup>CH<sub>4</sub> and different electron acceptors (sulfate, nitrate, ferrihydrite, humic acids). <sup>13</sup>CH<sub>4</sub>, <sup>12</sup>CH<sub>4</sub> (produced during methanogenesis) and <sup>13</sup>CO<sub>2</sub> were quantified using gas chromatography coupled to mass spectrometry. Electron acceptors were analyzed by Ion Chromatography and iron and sulfide by colorimetric methods. Microbial community analysis was done using 16S rRNA pyrosequencing and quantification of specific microbial groups was done using quantitative PCR.

### **Conclusions**

Slurry incubations gave evidence that AOM occurred only with sulfate as electron acceptor. Sulfide production occurred simultaneously with <sup>13</sup>CO<sub>2</sub> production and no methanogenesis occurred. Pyrosequencing analysis showed presence of ANME-2a/b and ANME-2d 16S rRNA genes. Higher abundance of ANME2a/b in incubations with methane and sulfate was confirmed with qPCR analysis. Bacterial pyrosequencing showed presence of SRB sequences belonging to SEEP-SRB1. This is the first report

that unequivocally shows that AOM is associated with SR in a freshwater environment.

**RHIZOSPHERIC MICROBIAL FLORA OF THE INDIAN ECOTYPE PTERIS VITTATA MEDIATING ARSENIC PHYTOREMEDIATION**

S. Tiwari<sup>1</sup>, B. Sarangi<sup>1</sup>

<sup>1</sup>*Environmental Biotechnology Division, CSIR-NEERI, Nagpur, India*

**Background**

Mitigation of arsenic (As) pollution is a topical environmental issue of high R&D priority. *Pteris vittata* is a proven arsenic hyperaccumulator and has capability of remediating arsenic from water and soil through phytoextraction. There are a few reports on rhizospheric microflora of *Pteris vittata* which could probably mediate As uptake by the plants, but there are no reports of such study on this Indian ecotype of *Pteris vittata* identified by us.

**Objectives**

This investigation was carried out to isolate and study role of rhizospheric microbes of the Indian ecotype *Pteris vittata*.

**Methods**

A glasshouse experiment was conducted to study rhizosphere microbes of *P.vittata* grown in soil amended with 25 mg arsenic Kg<sup>-1</sup> soil in the form of sodium arsenate for sixty days. A total of 12 bacteria cultures were isolated and marked as As1-As12 and they were further studied for Minimum Inhibitory Concentration, Arsenic transformation test and Plant Growth Promoting Characteristics (PGPRs) i.e. Siderophore, IAA and ACC deaminase.

**Conclusions**

The isolated microbes showed arsenic tolerance up to 1000ppm and have dual capacity of AsV reduction and AsIII oxidation. Out of the twelve isolates, As 1, 2, 11, 12 exhibited siderophore positive. Except As 3, 4, 5, 9 & 12, all produced IAA while ACC deaminase was absent in all isolates. These findings show the interaction between plant and microbes for As detoxification and remediation by this ecotype of *P.vittata* endogenous to India. Our study opens up further scope of using the isolated arsenic tolerant microbes for enhancing the As remediation process through phytoremediation.

<sup>4</sup>*Department of Geoinformatics,*

*Jan Evangelista Purkyně University in Ústí nad Labem Faculty of the Environment, Ústí nad Labem, Czech Republic*

**Background**

In the Protected Landscape Area Labské pískovce (Czech Republic) there is a series of sandstone caves accessible with climbing equipment prevailing; their access is subjected to permission and attendance recorded in the log-books.

**Objectives**

Investigation of the effect of attendance on the quantity, rough composition, stress indicators, and activities of microbial communities in cave-sediments in 14 caves using number of visitors and step -compression as the main tested factors.

**Methods**

Microbial communities were characterized by phospholipid fatty acid (PLFA) profiles and activities of extracellular oxidases, peroxidases, phosphatases, proteases, and glukosidases.

**Conclusions**

Sediment microbial communities were generally poor (low PLFA content, low activities). Step-compression increased significantly ratios of fungal/bacterial and G+/G- PLFA as well as PLFA of actinobacteria and activities of phosphatases, glukosidases, and peroxidases while decreased *trans/cis* PLFA indicator of microbial

stress. Number of visitors correlated positively with G+/G- ratio and negatively with soil moisture, *trans/cis* PLFA stress indicator, and activity of peroxidases. Overall the effect of attendance to sediment microbial communities was found significant and it is likely related to input of nutrients into caves. The results might serve as a supporting material for reconsidering of the cave attendance policy.

## **STUDY OF NEMATODE-BACTERIA INTERACTION IN PINE WILT DISEASE**

C. Vicente<sup>1</sup>, F. Nascimento<sup>2</sup>, Y. Ikuyo<sup>1</sup>, M. Mota<sup>2</sup>, K. Hasegawa<sup>1</sup>

<sup>1</sup>*Environmental Biology, Chubu University, Kasugai, Japan*

<sup>2</sup>*Biology, Universidade de Évora - ICAAM, Évora, Portugal*

### **Background**

Pine wilt disease (PWD) is one of the most threatening diseases for worldwide forestlands, and is caused by the plant parasitic nematode *Bursaphelenchus xylophilus*. Bacterial communities associated with the *B. xylophilus* are suggested to play a role in PWD development.

### **Objectives**

Our aim is to understand the contribution of nematode-associated bacteria (in particular, *Serratia quinovorans* FX1 and *Serratia marcescens* PWN146) in PWD, as well as their behavior towards *B. xylophilus*.

### **Methods**

Previously, we have characterized the phenotype of *S. quinovorans* FX1 and *S. marcescens* PWN146, and their performance under *in vitro* oxidative stress conditions, alone and in association with *B. xylophilus*. We are now analyzing both genomes and comparing both with endophytic and plant pathogenic bacteria.

### **Conclusions**

Both *Serratias* present phenotypic plasticity in traits that favour their fitness inside of the host tree (Vicente et al. 2011; Vicente et al., 2012), and under certain circumstances can help the nematode to overcome the hostile tree environment (Vicente et al., 2013). We believe that the beneficial association nematode-bacteria may be facultative and co-dependent of other unknown features (Nascimento et al. 2014).

## **DIVERSITY AND BIOTECHNOLOGICAL POTENTIAL OF THRAUSTOCHYTRIDS FROM THE CHINA'S COASTAL WATERS**

G. Wang<sup>1</sup>, Y. Duan<sup>1</sup>, S. Zhang<sup>1</sup>, Y. Liu<sup>1</sup>

<sup>1</sup>*Environmental Science, Tianjin Univeristy, Tianjin, China*

### **Background**

Thraustochytrids are unicellular and heterotrophic fungal-like marine protists with known low diversity and have long been known to produce diverse interesting bio-products. However, their diversity and biotechnological potential have been barely explored in the china's coastal waters.

### **Objectives**

Investigate the diversity of thraustochytrids using molecular and cultivation methods; explore the isolated strain in the production of biotechnological potential.

### **Methods**

Flow Cytometer, pyrosequencing, plate cultivation, fermentation, and HPLC analysis

### **Conclusions**

Thraustochytrids abundance displays significant spatial and temporal variations in the coastal waters and can surpass that of bacteroplankton. The molecular diversity of thraustochytrids is much higher than what we have known. Samples from contaminated areas tend to contain higher richness and diversity than those uncontaminated areas. The majority of recovered reads are members of the family Thraustochytriaceae. Thus, thraustochytrids were the dominant components of labyrinthulomycetes and presumably play significant role ocean carbon cycling the coastal waters. The culturable diversity of thraustochytrids is low in coastal waters. However, most of cultivated strains produces carotenoids, polysaccharides and proteases. Some of the stains produce significant amount polyunsaturated fatty acids (PUFA) (e.g. DHA) and saturated fatty acids. Thus, thraustochytrids can be used for the production nutraceuticals and biodiesel.

## **BIOCHAR COLONIZATION BY ANAEROBIC MICROORGANISMS**

M. Werner<sup>1</sup>

<sup>1</sup>*Leibniz-Institute for Agricultural Engineering Potsdam-Bornim, Potsdam, Germany*

Background: Terra preta do indio is a typical hortic anthrosol in the amazonas region derived from long-term human landscape cultivation. This distinct type of soil is characterized by a high storage capacity of plant nutrients as well as a high content of carbon enabling agriculture even on soils with low humus and/or nutrient content. Due to certain similarities in consistence and composition, biochar is recently discussed as a value artificial soil amendment to obtain similar positive effects on soil fertility like terra preta. In addition to the structural and compositional analysis of biochars the interaction of the chars with living microorganisms is studied, to explain the effect of biochar enriched soils from a microbiological point of view. Due to seclusion of a biogas system and the consequent creation of a separate world the study of effects by biochar colonization with microorganisms by minimizing the confounding factors is more easier compared with soil tries.

Objectives: In this study the microbial interaction caused by colonization, biofilm formation and degradation with two types of char (hydrochar and pyrolyzed char), which differs in degradation stability, is examined using a mesophilic gas lift biogas fermentation system.

Methods: In samples taken from mesophilic to thermophilic biogas system at various time points the bacteria:archaea ratio was determined by DNA-based quantitative PCR according to Yu et al. [1995].. In addition, the treated chars were investigated with respect to their surface properties by gas adsorption method (BET).

Conclusions: Caused by feedstock and process condition during carbonization the pyro-char shows higher stability regarding degradability while fermentation. This leads due to the colonization of the char to a measurable reduction of pore surfaces in the pyro-chars, whereas the instability of the hydrochars lead to an increase in the specific surface area compared with the unfermented sample. Most interesting is the dynamic not stable population in the microbial community over time under anaerobic digestive conditions.

**COMPARATIVE ANALYSIS OF THE MICROBIAL COMMUNITIES ON THE SURFACE OF MINERAL ENHANCED BIOCHARS**

J. YE<sup>1</sup>, T. THOMAS<sup>1</sup>, S. NIELSEN<sup>1</sup>, S. JOSEPH<sup>1</sup>

<sup>1</sup>SCHOOL OF BIOTECHNOLOGY AND BIOMOLECULAR SCIENCES,  
THE UNIVERSITY OF NEW SOUTH WALES, Sydney, Australia

**Background**

Biochar is a kind of porous material made by the pyrolysis of biomass under complete or partial exclusion of oxygen. It has applications in different areas, with the most important one being as an amendment to improve the quality of agricultural soils. Several studies reported significant changes for the microbial communities in bulk soil with biochar-treatment, whereas microbiota colonised on the surface of biochar is largely neglected.

**Objectives**

In this study, two types of mineral enhanced biochars, including kaolinite (Kao) and bentonite (Be), and non-enhanced biochar (Bam) were applied into soil with (F) or without (NF) traditional fertilisation (urea, superphosphate and potash) on a pot trial. We compared the differences of microbial communities on the surface of biochar and amended soil after 4-month incubation.

**Methods**

Total DNA was extracted from biochar particles and soil respectively and sequencing using the Illumina MiSeq platform.

**Conclusions**

Analysis of 2001281 quality-filtered sequences revealed high microbial diversity in these samples. Bray-Curtis distance-based non-metric multidimensional scaling (nMDS) analysis showed that the microbiota of biochar particle and soil were clearly separated into four clusters (soil vs. particle, F vs. NF). Samples in the NF cluster were observed to vary by biochar types. *Acidobacteria*, *Actinobacteria*, *Bacteroidetes*, *Proteobacteria* was detected as the dominant phyla regardless of particle and soil. Furthermore, unique OTUs in each samples were identified, three OTUs from the class *Gammaproteobacteria*, the family *Oxalobacteraceae*, the genus *Thiobacillus* were found significantly more abundant in biochar particles.

## **CHARACTERIZATION OF ENDOLYSINS FROM A VIBRIO PARAHAEMOLYTICUS BACTERIOPHAGE VPP-KF1**

H. Chang<sup>1</sup>, J. Hong<sup>1</sup>, N. Lee<sup>1</sup>, S. Choi<sup>1</sup>, G. Ok<sup>1</sup>

<sup>1</sup>Research group of food safety, Korea Food Research Institute, Seongnam-si Gyeonggi-do, Korea

### **Background**

*Vibrio parahaemolyticus* is a halophilic gram-negative bacterium in seawater and estuaries. It is one of the leading causes of seafood-related illness through the ingestion of raw or undercooked seafood and cross contamination from unsanitary cooking environments. Endolysin, a phage-encoded enzyme that breaks down bacterial peptidoglycan at the terminal stage of the phage reproduction cycle, is reported to be effective for the control of pathogenic bacteria as well as bacteriophage itself.

### **Objectives**

The purpose of this study was to examine lytic properties of endolysins from bacteriophage Vpp-KF1 infecting *Vibrio parahaemolyticus*.

### **Methods**

Lytic bacteriophage Vpp-KF1 infecting *Vibrio parahaemolyticus* was isolated from west coastal area of Korea, and its whole genome was sequenced and analyzed. Endolysin genes were identified in the bacteriophage genome, and then the endolysin genes were cloned and overexpressed in *Escherichia coli*. The endolysins were purified by Ni-NTA affinity chromatography. The effects of temperature and pH on the lytic activities, and the lytic spectrums of endolysins were determined by measuring changes in the optical density of cell suspension.

### **Conclusions**

Endolysin genes were successfully expressed in *E.coli* expression system, and the enzymes were purified as soluble forms. The endolysins were relatively stable and active over broad temperature (from 24°C to 55°C) and pH (from 2 to 10) ranges. The lytic spectrums were relatively narrow because those endolysins were effective mainly in *Vibrio* species when treated without EDTA. These results suggested that the bacteriophage Vpp-KF1 endolysins have potential as an alternative to antibiotics or antibacterial agents in controlling bacterial contamination.

### General virology and bacteriophages

#### THE METABOLIC EFFECTS OF PHAGE INFECTION: PHAGE SPECIFIC OR NOT?

J. De Smet<sup>1</sup>, M. Zimmermann<sup>2</sup>, M. Kogadeeva<sup>2</sup>, P.J. Ceysens<sup>3</sup>, B.G. Blasdel<sup>1</sup>, U. Sauer<sup>2</sup>, R. Lavigne<sup>1</sup>

<sup>1</sup>Division of Gene Technology Department of Biosystems, KU Leuven, Leuven, Belgium

<sup>2</sup>Institute of Molecular Systems Biology, Eidgenössische Technische Hochschule (ETH), Zürich, Switzerland

<sup>3</sup>Division of bacterial diseases, Scientific Institute of Public Health (WIV-ISP), Brussels, Belgium

#### Background

Bacterial viruses are fully dependent on their host cell metabolic resources to fuel their propagation. Through millions of years of co-evolution, many bacteriophages have acquired host genes in their genomes which can overcome biochemical bottlenecks in specific metabolic processes, and therefore were termed 'auxiliary metabolic genes' (Thompson *et al*, 2011).

#### Objectives

As such, the metabolic response to phage infection would vary depending on the number of AMG's in the genome of the phage. To gain additional insight in this topic, we studied the metabolic variations in an ubiquitous, gram-negative bacterium, *Pseudomonas aeruginosa*, under attack of six distinct lytic dsDNA phages.

#### Methods

We used state of the art metabolomics techniques (Fuhrer *et al*, 2011). A total of 6006 ions were measured, of which 918 were annotated to *P. aeruginosa* metabolites. After filtering 375 unique masses were retained, corresponding to 810 *P. aeruginosa* metabolites.

#### Conclusions

Using hierarchical clustering we saw that the metabolic response triggered by phage infection is not a general response but depends on the requirements of a specific phage. A pathway enrichment analysis showed that not all pathways were influenced equally. An example is the clear up regulation of the pyrimidine metabolism, which can be linked to a study from Enav *et al* in 2014 that showed that AMG's with a function in the pyrimidine and purine metabolism are enriched in the viral gene pool. These results indicate that unique AMG's might play a crucial role in the specific host metabolic response induced by different phages.

**LACTOCOCCUS GARVIEAE'S VIRUSES: AN INSIGHT INTO TEMPERATE AND VIRULENT BACTERIOPHAGES**

G. Eraclio<sup>1</sup>, D. Tremblay<sup>2</sup>, S. Moineau<sup>2</sup>, G. Ricci<sup>1</sup>, G. Fortina<sup>1</sup>

<sup>1</sup>Department of Food Environmental and Nutritional Sciences,  
Università degli Studi di Milano, Milano, Italy

<sup>2</sup>Département de Biochimie de Microbiologie et de Bioinformatique, Université Laval,  
Québec City, Canada

**Background**

*Lactococcus garvieae*, one of the most important pathogens in the aquaculture sector, has been recently recognized as an opportunistic human pathogen. However, little is known about the factors controlling of its growth.

**Objectives**

The aim of this project is to isolate and characterize temperate and virulent phages of *L. garvieae*.

**Methods**

Forty-five *L. garvieae* strains isolated from various ecological niches were tested for the presence of inducible prophages. Virulent phages were also isolated from different environments. Morphological and genomic characteristics of the new phages were studied through transmission electronic microscope (TEM), DNA restriction profile, protein profile, host range, and in few cases, genomic sequences.

**Conclusions**

Twenty temperate phages belonging to the *Siphoviridae* family and five new virulent phages able to infect *L. garvieae* strains have been isolated and partially characterized. Temperate phages, integrated into the genome of the host cell, promoted genome plasticity and appeared to be involved in gene mobilization. Virulent and strain-specific phages may be useful as alternatives to antibiotics to treat *L. garvieae* infections.

### **ANALYSIS OF CDT-I PHAGE PRODUCTION IN ESCHERICHIA COLI**

A. Hinenoya<sup>1</sup>, S.P. Awasthi<sup>1</sup>, M. Asakura<sup>1</sup>, S. Yamasaki<sup>1</sup>

<sup>1</sup>Graduate School of Life and Environmental Sciences, Osaka Prefecture University, Izumisano, Japan

#### **Background**

Cytotoxic distending toxin (CDT)-producing *Escherichia coli* (CTEC) have been isolated from patients with diarrhea. Previously, we have reported that *cdt-I* genes in *E. coli* are located in genetically diverse lambdoid phages, and CDT-I phage (CDT-I $\Phi$ ) could be transferred horizontally between *E. coli* in pathotype-specific manner.

#### **Objectives**

In this study, CDT-I $\Phi$  was comprehensively analyzed to understand underlying mechanisms of its production.

#### **Methods**

Culture supernatants of 46 CTETC-I strains were examined for CDT-I $\Phi$  production by plaque assay with *E. coli* C600 both in the presence and absence of mitomycinC (MMC). Plaque assay was also performed with *DrecA-E. coli* (strain TOP10F') and its *recA* complement as a recipient strain. Presence of other lambdoid phages was examined by using 23 known *cI* gene-probes.

#### **Conclusions**

Among analyzed strains belonging to diverse EPEC and non-EPEC, only EPEC O127 and O142 could produce CDT-I $\Phi$  plaques. All the CTETC-I O142 produced CDT-I $\Phi$  both in the presence and absence of MMC, whereas CTETC-I O127 produced only in the presence of MMC. However, under identical host background (C600), these phenomena disappeared. CDT-I $\Phi$  plaque was not produced against *DrecA-E. coli*, whereas produced when complemented with *recA* gene. CTETC-I O127 strains harbored 6 or 7 *cI* genes, whereas O142 had 2~4. CDT-I $\Phi$  production was differently regulated in CTETC-I O127 and O142, suggesting involvement of host factors, which might contribute to inhibit or stimulate spontaneous CDT-I $\Phi$  induction in these serogroups in a RecA-dependent pathway. Moreover, intra-prophage interactions with O127-specific prophages could be related to CDT-I $\Phi$  production.

**BACTERIOPHAGES ISOLATED FOR THE CONTROL OF PATHOGENIC VIBRIO HARVEYI IN SHRIMP HATCHERIES**

I.S. Bright Singh<sup>1</sup>, S.S. Pai<sup>1</sup>, A.A. Anas<sup>1</sup>

<sup>1</sup>National Centre for Aquatic Animal Health,  
Cochin university of Science and Technology, Cochin, India

Phage therapy has been accepted as alternative to chemotherapy in aquaculture systems especially in shrimp larval production. Uniqueness of bacteriophages as therapeutics is their self-replicating character and specificity to the target organisms. However, concerns exist with their use in vivo as they may turn out to be the agents of generalized transduction in the environment mediating transfer of genes among bacteria. This is important because phages selected for therapeutic purpose must not carry virulence genes or properties conferring antimicrobial resistance and toxin genes to the host bacteria. Moreover, therapeutic phages should not become latent as well during their life cycle. Using an enrichment method, bacteriophages were isolated from sediment and water samples from Vembanad estuary, Cochin, India employing 12 isolates of *Vibrio harveyi*. By this method four phage lysates were obtained, purified by soft agar overlay method, titred and stocked at 4° C and stability checked over a year. Host range of the phage was assessed against 162 bacterial isolates spanning 14 species to which they showed broad spectrum lytic activity. One phage was lytic to both *V. alginolyticus* and *V.*

*parahaemolyticus* potentially pathogenic to shrimp and other aquatic animals in culture systems. Lytic efficiency of all phages was checked on their respective host bacterial species. In all cases the phages were able to arrest growth of *V. harveyi* for about 5-6 hours after which phage resistant forms emerged and began to dominate. By electron microscopy, three of the phages were identified as Myovirus-like with icosahedral head, short collar and contractile tail. The fourth one was Siphovirus-like with icosahedral head and long, flexible, helical non-contractile tail. It was infective to 62 % *V. harveyi* isolates tested and to its near taxonomical neighbours, *V. alginolyticus* and *V. parahaemolyticus*. Development of resistance or lysogenization is an impediment in the development of phage therapy in aquaculture necessitating deeper understanding on their genome and phage-host dynamics in the environment.

## **HIGH FREQUENCY OF MUTATOR STRAINS INDUCED BY PHAGE GHOST ATTACHMENT**

T. Kenzaka<sup>1</sup>, K. Tani<sup>1</sup>

<sup>1</sup>*Faculty of Pharmacy, Osaka Ohtani University, Tondabayashi, Japan*

### **Background**

Lytic phages induce bacterial mortality and contribute to the global carbon cycle. Because their main impact on the host is lysis of the cell, short-term contact between the host and phage is considered genetically less important unless genetic exchange occurs.

### **Objectives**

In order to understand the genetic impact of a lytic phage on the host, we examined the fate of host cells after attack by a lytic phage and the mutant frequency of cells that did not undergo lysis.

### **Methods**

After incubating *Escherichia coli* with phage T4 or the ghost for 10 min, the cells were placed on LB plates and allowed to grow. Colonies that escaped lysis were randomly selected. Mutant frequency to nalidixic acid resistance in the escaped colonies was examined. The insertion of phage DNA and mutations on the genomes of mutator strains which showed elevated mutant frequencies were examined by whole genome sequencing analysis. Role of DNA polymerase IV gene (*dinB*) was examined with RT-PCR and *dinB*-deficient mutant.

### **Conclusions**

After the attachment of the phage T4 to *E. coli* cells, 1% *E. coli* cells showed an approximately 40-fold increase in mutant frequency. Phage ghosts increased the incidence of mutator strains. Phage DNA was absent in the mutator strains. The attachment of the phage ghosts to the host induced the mRNA expression of the *dinB*, resulting host genome mutagenesis. These results suggested that attachment of a lytic phage alters the genome of the host that has escaped lysis at high frequency, without relying on gene transfer.

## **TACMAN-BASED REAL-TIME PCR FOR QUANTITATIVE DETECTION OF VIRAL HEMORRHAGIC SEPTICEMIA VIRUS**

I. Kim<sup>1</sup>, M. Jeong<sup>1</sup>, J. Lee<sup>1</sup>

<sup>1</sup>*Biological Sciences and Biotechnology, Hannam University, Daejeon, Korea*

### **Background**

Viral hemorrhagic septicemia virus (VHSV) is known as the most common cause of diseases in fisheries. VHSV infects fishes of fresh water as well as ocean. Natural VHSV may cause of disease by introducing into fish farm. A huge amount of fry are stocked into the coast.

### **Objectives**

Therefore development of VHSV detection method is required. For the detection of VHSV, enzyme immunoassay using polyclonal antibodies, western blotting, and electron microscopy are mainly used. However these methods have limitation to detect latent infection and an initial viral disease. Recently nucleotide amplification test using polymerase chain reaction (PCR) has been used widely for rapid and specific detection of viruses.

### **Methods**

In this study, TaqMan-based real-time PCR assays to detect VHSV was developed and validated. Specific primers for amplification of VHSV were selected, and VHSV was quantified by use of TaqMan probe.

### **Conclusions**

The sensitivity for VHSV real-time PCR was calculated to be  $8.10 \times 10^{-1}$  TCID<sub>50</sub>/mL. The TaqMan probe real-time PCR assay was proven to be reproducible and very specific to VHSV. Therefore, it was concluded that this rapid, specific, and robust assay could replace the conventional assay for detection of VHSV.

## **COMPARATIVE ANALYSIS OF AVIAN PATHOGENIC ESCHERICHIA COLI PHAGES**

I. Mutuku<sup>1</sup>, J. Mast<sup>2</sup>, A. Moodley<sup>3</sup>, P. Butaye<sup>4</sup>

<sup>1</sup>Bacterial Disease, CODA-CERVA, Ukkel, Belgium

<sup>2</sup>Unit Electron Microscopy Interactions and Surveillance, CODA-CERVA, Ukkel, Belgium

<sup>3</sup>Department of Veterinary Disease Biology, University of Copenhagen, Ukkel, Belgium

<sup>4</sup>Department of Veterinary Medicine, Ross University, St. Kitts, St Kitts & Nevis

### **Background**

Avian pathogenic *Escherichia coli* (APEC) causes colibacillosis and significant economic losses in the poultry industry.

### **Objectives**

To isolate and characterize poultry fecal phages that are active against *Escherichia coli* serogroups O1, O2, and O78; the main causative agents of avian colibacillosis.

### **Methods**

Lytic phages (71) were isolated from poultry fecal material and their lytic spectrum of activity was determined against 61 APEC (O1, O2, O78 serotypes) strains collected from Belgium. The phages with the broadest activity spectrum were characterized by, restriction-fragment length polymorphism (RFLP). Based on their obligate lytic characteristics and broad host spectrum of activity, some were selected for whole genome sequencing using the Nextera XT™ kit (Illumina, San Diego, USA). The morphology of the phages was determined by negative staining and Transmission Electron Microscopy (TEM).

### **Conclusions**

Phages PhK7, PhK10S, PhK10L, PhK12B, PhK21, PhK22, PhK12A, PhK13, PhK26, PhK2, PhK3, PhK6, Ph431, PhC3 and PhK33C were isolated and further characterized. The most active phages were Ph431 active against 70% (43/61) of the APEC strains, PhC3 against 68% (42/61), PhK33C against 41% (25/61), PhK10S against 26% (16/61), Ph12A 19% against (12/61).

In all samples, particles were observed consisting of a non-enveloped head with icosahedral symmetry and a tail with helical symmetry; characteristics attributing the particles to the bacteriophage order of the Caudovirales and belonged to families Myoviridae and Siphoviridae.

Genome analysis of some of phages indicated there were close relatives of Siphoviridae present under the unclassified Tunalikevirus (PhK2, PhK3, PhK6) and unclassified Siphoviridae (PhK10S, PhK7, PhK10L, PhK12B, PhK21, PhK22, Ph12A, PhK26, PhK13).

**OBSERVATION OF PHAGE-ANTIBIOTIC SYNERGY IN VARIOUS COMBINATIONS OF BACTERIA, BACTERIOPHAGE, AND ANTIBIOTICS**

H. Myung<sup>1</sup>, K. Park<sup>1</sup>

<sup>1</sup>Bioscience and Biotechnology, Hankuk University of Foreign Studies, Yongin, Korea

**Background**

When phages infect bacteria cultured in the presence of sub-lethal doses of antibiotics, sizes of phage plaques significantly increase. This phenomenon is known as phage-antibiotic synergy (PAS).

**Objectives**

We extended observation of PAS to a wide variety of bacteria-phage pairs with four different classes of antibiotics.

**Methods**

In the presence of sublethal dose of various antibiotics, phage growth and burst was measured.

**Conclusions**

PAS was observed in both Gram-positive and Gram-negative bacteria. Cell wall synthesis inhibitors and DNA metabolism inhibitors generally induced PAS. Some protein synthesis inhibitors induced PAS, while others did not. The use of sub-lethal dose of ampicillin, cefotaxime, ciprofloxacin, or mitomycin C allowed formation of highly visible plaques of increased sizes when various bacteriophages infected Gram-positive bacteria such as *Staphylococcus aureus*, *Bacillus cereus*, and *Enterococcus faecalis*. In Gram-negative bacteria, *Escherichia coli* and *Pseudomonas aeruginosa* phages showed increased plaques in the presence of sub-lethal dose of cefotaxime, ciprofloxacin, or mitomycin C. We also confirmed that cells stressed with  $\beta$ -lactam and quinolone antibiotics filamented or swelled extensively. Burst sizes of bacteriophages also increased in the presence of antibiotics. Increase of production of phages in the presence of antibiotics was also shown in vivo using *Caenorhabditis elegans* as a model animal. Induction of SOS response was observed in many cases of PAS, but not all. Enlarged production facility allowed increased DNA replication, transcription, and translation of phage leading to PAS.

**IMMUNOGENICITY EVALUATION OF HEPATITIS B (HB) VACCINES UTILIZED IN THE EXPANDED PROGRAMME ON IMMUNIZATION (EPI) IN SOUTH-EASTERN NIGERIA**

A.N. Oli<sup>1</sup>, R.U. Agu<sup>2</sup>, N.T. Ujam<sup>1</sup>, C.O. Esimone<sup>1</sup>

<sup>1</sup>*Department of Pharmaceutical Microbiology and Biotechnology, Nnamdi Azikiwe University, Agulu, Nigeria*

<sup>2</sup>*Biopharmaceutics and Drug Delivery Laboratory College of Pharmacy 5968 College Street PO Box 15000, Dalhousie University, Halifax, Canada*

**Background**

Vaccination effectively enables the control of many infectious diseases. However, we cannot always avoid the problem of adverse reactions accompanied by vaccination. The most common cause of vaccine-related side-effects is human errors linked to logistics problems.

**Objectives**

This study investigated

- whether or not the Hepatitis B (HB) Vaccines in use in South-East Nigeria have the features and characteristics needed for them to satisfy stated or implied needs.
- the efficiency of cold-chain facilities in South-east, Nigeria

**Methods**

The immunogenic quality of the vaccines was determined by quantitation of the antibody titer (using ELISA method) in vaccinated laboratory animals.

The mean antibody titers for the control, Enugu/Ebonyi, Imo, Anambra and Abia States' vaccines were 8.7, 398.2, 353.7, 396.3 and 369.6 mIU/mL respectively. The vaccine used as the control did not produce sufficient protective effect (antibody titer was less than 10 mIU/mL). One-way analysis of variance shows that the means of all the samples, including the control, are significantly different at  $P < 0.05$ . Also, Bartlett's test for equal variances showed that the variances are also significantly different. The vaccines do not all produce equal protection ( $P$  value was  $< 0.0001$ ), their antibody titers being statistically different. The Dunnett's Multiple Comparison Test shows that the mean antibody titers produced by the vaccines from the States significantly differ from the value produced by the control vaccine at  $P < 0.05$ .

**Conclusions**

All the vaccines tested produced the required amount of protective antibodies. The cold-chain facilities, at the time of vaccines collection, are in good condition.

**BACTERIOPHAGE ENDOLYSIN LYT  $\mu$ 1/6: BINDING ACTIVITY REVEALED!**

L. Tisakova<sup>1</sup>, A. Godany<sup>2</sup>

<sup>1</sup>Dept. of Genomics and Biotechnology,

Institute of Molecular Biology Slovak Academy of Sciences, Bratislava, Slovakia

<sup>2</sup>Dept. of Biology,

University of Ss. Cyril and Methodius in Trnava Faculty of Natural Sciences, Trnava, Slovakia

**Background:** Bacteriophage endolysins are phage-encoded peptidoglycan hydrolases by which bacteriophage are released from bacterial cells and which are effective in bacterial cell wall lysis, when applied exogenously. The gene product of orf50 from actinophage  $\mu$ 1/6 of *Streptomyces aureofaciens*, producing tetracycline, is endolysin Lyt  $\mu$ 1/6. It shows a two-domain modular structure, consisting of an N-terminal catalytic and a C-terminal binding domain (CBD). BLAST analysis of Lyt  $\mu$ 1/6 CBD disclosed the presence of a peptidoglycan binding domain type 1 (PG\_binding\_1) which was also confirmed by *in vitro* experiments.

**Objectives:** The main aim of this study was to determine the part of the Lyt  $\mu$ 1/6 CBD responsible for binding activity towards the *Streptomyces* cell wall, as well as to study concrete truncated forms of it in fusion with green fluorescent protein (GFP).

**Methods:** The sequence of the Lyt  $\mu$ 1/6 CBD and truncated forms of it were cloned and expressed in *Escherichia coli*. All recombinant proteins were isolated and partially purified with conventional chromatographic methods. The ability of the CBD truncated variants fused to GFP to bind to the substrate consisting of *Streptomyces aureofaciens* NMU cells was demonstrated by specific binding assays. Subsequently, the binding of the CBD fusion products was visualized by fluorescence microscopy.

**Conclusions:** It could be assumed that the binding activity of the CBD is located within the three helices of the PG\_binding\_1 domain. This fact is supported by a negative control which is a construct of the N-terminal part of the Lyt  $\mu$ 1/6 CBD, showing no binding activity.

**Keywords:** bacteriophage endolysin, *Streptomyces aureofaciens*, cell wall binding domain (CBD), green fluorescent protein (GFP), truncations, binding activity

**Acknowledgements:** This work was supported by funding from the Slovak Academy of Sciences VEGA 2/0123/14.

**THE ROLE OF AVIN08930 IN BIOSYNTHESIS OF POLY-B-HYDROXYBUTIRATE AND ALKYLRESOLCINOLS IN AZOTOBACTER VINELANDII**

L. Bedoya-Perez<sup>1</sup>, S. Moreno<sup>1</sup>, J.A. Hernandez<sup>1</sup>, G. Espin<sup>1</sup>

<sup>1</sup>Molecular Microbiology, Institute of Biotechnology-UNAM, Cuernavaca, Mexico

**Background**

*Azotobacter vinelandii* is a Gram-negative bacterium able to synthesize polyhydroxybutyrate (PHB), a polyester to produce biodegradable plastic. *A. vinelandii* can undergo a differentiation process to produce resistant-desiccation cysts. During the encystment, the bacterium synthesizes the phenolic lipids alkylresorcinols (ARs), which replace the membrane phospholipids. The operons *phbBAC* and *arsABCD* encode the enzymes necessary for PHB and ARs synthesis and their transcription are activated by PhbR and ArpR, respectively.

The two component regulatory system GacS/GacA is essential for biosynthesis of PHB and ARs, since a *gacA* mutation abrogates their production. GacA activates the transcription of genes encoding sRNAs *rsmZ1-7* and *rsmY*, which bind to RsmA; a small protein that blocks the translation of *phbR* and *arpR* mRNAs. Because inactivation of *rsmA* in a *gacA* mutant did not restore the PHB and ARs synthesis, we hypothesize that there is another pathway by which GacS/GacA controls the biosynthesis of PHB and ARs in *A. vinelandii*.

**Objectives**

To characterize the role of Avin08930 on PHB and ARs in *A. vinelandii*.

**Methods**

A bioinformatic analysis of *A. vinelandii* genome allowed us to identify a consensus binding site for GacA in the Avin08930 promoter. By using qPCR and transcriptional fusions, we determined if Avin08930 expression is dependent of GacA. An Avin08930 mutant was constructed and PHB and ARs synthesis as well as *phbB* and *arsA* expression were determined in this strain.

**Conclusions**

The transcription of Avin08930 is activated by GacA. In the Avin08930 mutant the *phbB* and *arsA* expression as well as the PHB and ARs levels were reduced.

<sup>2</sup>Department of Microbiology, Jagiellonian University, Krakow, Poland

<sup>3</sup>Department of Veterinary Animal Reproduction and Welfare,  
University of Agriculture in Krakow, Krakow, Poland

### **Background**

Gene transcription regulatory pathways are crucial for adaptation to constantly-changing environmental conditions. These include pathogen-host interactions. Up until now, few such systems have been characterised for *Staphylococcus aureus* and simultaneously demonstrated as relevant for virulence.

### **Objectives**

This study presents a comprehensive analysis of a three-gene operon *saoABC*, which likely constitutes yet uncharacterised staphylococci-specific gene expression regulatory system. The research is focused on the operon structure and conservation among species of *Staphylococcus* genus, DNA-binding properties of SaoC protein, changes in *saoABC* operon genes expression triggered by stress stimuli, links between *saoABC* operon and known gene transcription regulatory systems as well as on differences between phenotypes of the wild type and the null mutants of *saoA* and *saoC* genes.

### **Methods**

The applied methods include comparative genomic analysis, heterologous SaoC protein expression and its purification, Real-Time PCR gene expression quantification, allelic replacement, virulence analysis in chicken embryo model and intracellular survival within human gingival fibroblasts and keratinocytes.

### **Conclusions**

The revealed features of *saoABC* operon convincingly suggest that it is a novel operon of a transcription regulation system, likely of a yet uncharacterised alternative sigma factor. The changes in the operon genes expression specifically induced by starvation and acidification point out the possible role of *saoABC* in intracellular survival of staphylococci in host cells.

<sup>2</sup>IRI-UGSF, CNRS - Université de Lille - Sciences et Technologies, Villeneuve d'Ascq, France

<sup>3</sup>Dept. Microbiology & Molecular Medicine, University of Geneva, Geneva, Switzerland

**Background**

In *Caulobacter crescentus* cell cycle is controlled at multiple levels by a plethora of regulators, such as GcrA, a putative transcriptional regulator with no functional characterization. Another regulator involved in controlling gene expression is CcrM, a GAnTC-specific N6-adenosine methylase active only at the end of S-phase; as a consequence, at every round of replication a fully methylated promoter of a gene gives two different hemi-methylated copies.

**Objectives**

Here we investigated *in vivo* and *in vitro* the role of GcrA during the S-phase on the transcription of important cell cycle genes that are controlled by CcrM.

**Methods**

We used a combination of ChIP (chromatin-immunoprecipitation), biochemical and biophysical experimentation and genetics to show that GcrA is a dimeric DNA-binding protein that preferentially targets promoters harbouring CcrM methylation sites in *Alphaproteobacteria*. After tracing CcrM-dependent promoter marks at a genome-wide scale, we showed that these marks recruit GcrA *in vitro* and *in vivo*. Moreover in the presence of a methylated target, GcrA recruits the RNA polymerase to promoters, consistent with its role in transcriptional activation. *In vitro* transcription assay using purified GcrA and RNAP on several GcrA-regulated genes along the chromosome showed that GcrA is a modulator of transcription that activates or represses depending on the methylation state of promoters. We confirmed this observation *in vivo* using RNA-FISH, revealing in addition a potential role of GcrA in spatial regulation of transcription.

**Conclusions**

In conclusion from our results we propose a novel model of methylation-dependent transcriptional regulation that modulates the expression of important genes during cell cycle.

## **CROSS-REGULATION OF MULTIPLE DISPARATE GENE CLUSTERS BY PAS-LUXR TRANSCRIPTIONAL REGULATORS**

C.M. Vicente<sup>1</sup>, E. García Barreales<sup>1</sup>, T.D. Payero<sup>1</sup>, J. Santos-Aberturas<sup>1</sup>,  
A. de Pedro<sup>1</sup>, J.F. Aparicio<sup>1</sup>

<sup>1</sup>Molecular Biology Department, University of León, Leon, Spain

### **Background**

PAS-LuxR regulators are highly conserved proteins devoted to the control of antifungal production by binding to operators located in given promoters of polyene biosynthetic genes. These regulators have been found to be encoded in all know biosynthetic gene clusters of polyene polyketides, and hence considered pathway-specific modulators.

### **Objectives**

The canonical operator of PimM, archetype of this class of regulators, has been used to search for putative targets of orthologous protein PteF in the genome of *Streptomyces avermitilis*.

### **Methods**

We have used bioinformatic and electrophoretic mobility shift techniques to identify PimM binding sites along the genome, and mutants in *pteF* for the functional characterization of selected operators.

### **Conclusions**

Contrary to the stablished opinion, PAS-LuxR regulators may control directly many different processes previously unforeseen, such as genetic information processing, DNA replication and repair, energy, carbohydrate, and lipid metabolism, morphological differentiation, transcriptional regulation, and other secondary metabolites biosynthesis. To prove that, we demonstrate that PteF, is able to cross-regulate the biosynthesis of the ATP-synthase inhibitor oligomycin in addition to that its canonical target filipin. Our results place these regulators as wide-domain modulators in regulation networks, and open new possibilities for the enhancement and awakening of metabolite production in *Streptomyces*.

**TRANSCRIPTOMIC ANALYSIS OF THE MUTANT STREPTOMYCES  
CLAVULIGERUS PSCL4-: ACTIVATION OF CRYPTIC BIOSYNTHETIC GENE  
CLUSTERS**

R. Álvarez-Álvarez<sup>1</sup>, E. García Barreales<sup>1</sup>, A. Rodríguez-García<sup>1</sup>, J.F. Martín<sup>1</sup>,  
P. Liras<sup>1</sup>

<sup>1</sup>Molecular Biology, University of León, Leon, Spain

**Background**

*S. clavuligerus* is a versatile and industrially important strain characterized by its ability to produce several economic relevant bioactive compounds such as cephamycin C and the  $\beta$ -lactamase inhibitor clavulanic acid. *S. clavuligerus* genome harbours 48 gene clusters encoding potential secondary metabolites. Under experimental conditions these clusters are not expressed ("silent clusters"), are expressed at very low levels producing undetectable amounts of the compound and in many cases the final product structure encoded by the cluster is unknown ("cryptic clusters"). A large part (21%) of the wild type genome is located in a 1.8 Mb megaplasmid that greatly influences secondary metabolites biosynthesis even if the secondary metabolites are chromosomally encoded.

**Objectives**

The objective is to analyze the differential expression between the wild strain and a pSCL4-deleted mutant and identify the activation of cryptic gene clusters in this mutant.

**Methods**

Deletion of pSCL4 was performed on the wild type *S. clavuligerus* ATCC 27064 using the Redirect Method . Microarray (*Agilent 8x15K*) data were normalized and analyzed with the *Bioconductor package limma*.

**Conclusions**

We demonstrated that the absence of linear megaplasmid pSCL4 induced holomycin overproduction, (*S. clavuligerus* is holomycin non-producer). The transcriptomic results have shown the expression of several cryptic gene clusters in *S. clavuligerus* pSCL4-. Therefore, the extrachromosomal-loss elements may be a strategy for the cryptic clusters activation in this microorganism.

## **CHARACTERIZATION OF SFBR, AN AUTOREGULATOR RECEPTOR FROM STREPTOMYCES FILIPINENSIS**

E. García Barreales<sup>1</sup>, T.D. Payero<sup>1</sup>, C.M. Vicente<sup>1</sup>, A. de Pedro<sup>1</sup>, J.F. Aparicio<sup>1</sup>

<sup>1</sup>Molecular Biology, University of León, Leon, Spain

### **Background**

Gamma-butyrolactones are small signaling molecules that are mainly produced by *Streptomyces* species. They have been shown to affect secondary metabolism and/or morphological differentiation by binding to specific cytoplasmic receptors and therefore inhibiting their binding to target DNA sequences.

### **Objectives**

Identification and characterization of a gamma-butyrolactone receptor (GBR) encoding gene from *Streptomyces filipinensis*, the industrial producer of the polyene antibiotic filipin.

### **Methods**

A genomic library of *S. filipinensis* DSM 40112 was screened with a probe designed from a HTH DNA-binding motif conserved among autoregulator receptors. A putative receptor encoding gene (*sfbR*) was found and sequenced. Characterization of this gene was performed using gene replacement and complementation techniques.

### **Conclusions**

The *sfbR* gene encodes a putative gamma-butyrolactone receptor protein which shows homology with other described GBRs such as AvaR from *S. avermitilis* or Brp from *S. clavuligerus*. Contrary to what occurs with many GBR-encoding genes, an adjacent gene encoding a gamma-butyrolactone biosynthetic enzyme was not found. Gene deletion resulted in a significant decrease in filipin production while complementation restored parental production, thus suggesting that SfbR positively controls the filipin biosynthetic genes. Moreover, *sfbR* deletion resulted in altered morphological differentiation when the mutant strain was grown on different solid media. Our results indicate that the SfbR protein regulates both sporulation and filipin production in *S. filipinensis*.

<sup>4</sup>Department of Environmental Biotechnology,  
UFZ Helmholtz Centre for Environmental Research, Leipzig, Germany

**Background**

*Pseudomonas fluorescens* spp. are present in all major natural environments, and able to quickly adapt to environmental modifications. Physiologically this adaptation depends primarily on membrane lipid composition and on its capacity to adjust membrane lipids in terms of environmental modifications. Previously we have already characterized the phospholipid composition of *P. fluorescens* [1].

**Objectives**

The aim of this work was to establish if the response to increasing temperature involves changes in the structure and the composition of *P. fluorescens* phospholipids at different phases of growth. The lipidomes of two *P. fluorescens* strains from different ecological niches : one clinical isolate MFN1032 and one airborne MFAF76a, were investigated at 28°C and 37°C.

**Methods**

To investigate *Pseudomonas* lipidome, MALDI-TOF MS Imaging was coupled to HPTLC. Additionally, NMR spectroscopy led to precise the phospholipid head group identification.

**Conclusions**

In stationary growth phase *P. fluorescens* produces a new phospholipid class: phosphoaminolipid (PAL).

Results provide evidence that next to the increasing of the temperature *P. fluorescens* is able to modify its phospholipid composition using two pathways. First the increasing of degree of unsaturation of fatty acid chains controls the membrane fluidity. Additionally the increase of the synthesis of anionic phospholipids (e.g. phosphatidylglycerol) results in the membrane charge changes. Physiologically, these two pathways allow *P. fluorescens* to adapt to stress conditions.

**FINE TUNING OF METABOLISM: THE ROLE OF CRC/CRCZ-CRCY SYSTEM IN INTEGRATING GLUCONEOGENIC AND GLYCOLYTIC METABOLISM IN PSEUDOMONAS PUTIDA**

R. La Rosa<sup>1</sup>, J. Nogales<sup>2</sup>, F. Rojo<sup>1</sup>

<sup>1</sup>Department of Microbial Biotechnology, Centro Nacional de Biotecnología - CSIC, Madrid, Spain

<sup>2</sup>Department of Environmental Biology, Centro de Investigaciones Biológicas - CSIC, Madrid, Spain

**Background**

In *P. putida*, the Crc protein and the small RNAs CrcZ and CrcY are key players in carbon catabolite repression (CCR), which facilitates the assimilation of the most efficient carbon sources, improving growth rate and fitness. Succinate and glucose are good carbon sources for *P. putida*, but elicit a weak CCR. Little information is available on the regulatory and metabolic interactions when both compounds are present. The choice between them is crucial on driving a metabolism focused on glucose consumption (glycolytic), or an inverse configuration directed to gluconeogenesis (succinate consumption and synthesis of sugars).

**Objectives**

The aim was to clarify whether there is a preference for succinate or glucose, and whether the Crc-dependent CCR has a role in coordinating metabolism when cells grow with a mixture of succinate and glucose at non-limiting concentrations.

**Methods**

We undertook an integrative approach combining metabolic, transcriptomics and constraints-based metabolic flux analyses.

**Conclusions**

Succinate was consumed faster than glucose and allowed a higher growth rate. However, both compounds were co-metabolised when provided simultaneously. CrcZ and CrcY levels were lower when both substrates were present than when only one of them was provided, suggesting a role for Crc in coordinating metabolism. Flux distribution analyses suggested that, when both substrates are present, Crc works to organize a metabolism in which carbon compounds flow in two opposite directions: from glucose to pyruvate, and from succinate to pyruvate. Therefore, Crc serves not only to favour the assimilation of preferred compounds, but also to balance the carbon fluxes, optimising metabolism and growth.

<sup>1</sup>Department of Bacteriology and Immunology,  
Research Programs Unit Immunobiology, University of Helsinki, Finland

<sup>2</sup>Department of Bacteriology and Immunology,  
Research Programs Unit Immunobiology and Helsinki University Hospital,  
University of Helsinki, Finland

#### **Background**

In previous studies we observed that Hfq strongly downregulates the LrhA (LysR homologue A) expression in *Yersinia enterocolitica*. Hfq was first identified as a host bacterial factor required for the replication of bacteriophage Q $\beta$  RNA. Now it is known that Hfq plays a crucial role in global post-transcriptional regulation network as an RNA chaperone that binds and stabilizes small regulatory RNAs. On the other hand, LrhA was shown to regulate negatively motility, chemotaxis and flagella synthesis in *Escherichia coli*.

#### **Objectives**

In this work we wanted to elucidate the role that LrhA plays in the phenotype of the *hfq* mutant of *Y. enterocolitica*.

#### **Methods**

The *hfq* and *lrhA* genes were knocked out to create single and double mutants for subsequent analyses. The mutant strains were complemented *in trans* by functional *hfq* and *lrhA* genes. LrhA was overexpressed from an IPTG-inducible plasmid. The strains were analysed for motility, biofilm formation, growth rate and mannitol utilization affected in the *hfq* single mutant.

#### **Conclusions**

In the *lrhA hfq* double mutant we could observe partial or full restoration of such features as growth rate, motility, biofilm production and mannitol utilization. On the other hand, overexpression of LrhA in wild type bacteria caused hypermotility and different colony morphology on mannitol-containing *Yersinia* selective agar plates. Our results thus showed that several alterations in physiology present in the *hfq* mutant of *Y. enterocolitica* are mediated by increased expression of LrhA.

**AZOARCUS ANAEROBIUS 1,3-DIHYDROXYBENZENE (RESORCINOL)  
ANAEROBIC DEGRADATION PATHWAY IS CONTROLLED BY THE  
COORDINATED ACTIVITY OF TWO SIGMA-54-DEPENDENT REGULATORS**

D. Pacheco<sup>1</sup>, A. Molina-Fuentes<sup>1</sup>, P. Marín<sup>1</sup>, S. Marqués<sup>1</sup>

<sup>1</sup>*Environmental Protection, Estación Experimental del Zaidín-  
Consejo Superior de Investigaciones Científicas, Granada, Spain*

**Background**

The obligate anaerobe *Azoarcus anaerobius* degrades resorcinol by an oxidative reaction where the aromatic ring is hydroxylated at position 4 to render hydroxyhydroquinone (HHQ)<sup>1</sup>. The three enzymatic steps are transcribed in three different operons controlled by two bacterial enhancer-binding proteins (bEBP) that share 97% identity, RedR1 and RedR2<sup>2,3</sup>.

**Objectives**

The work aims at understanding the coordinate expression of the pathway genes in response to the presence of the substrate by elucidating the specific activation mechanism of each regulator.

**Methods**

Genetic and biochemical approaches were used to define the activation mechanism of the two regulators.

**Conclusions**

Despite the high sequence identity between RedR1 and RedR2, they are controlled by different activation mechanisms: in the absence of effector, RedR2 is kept inactive through binding to the membrane protein BtdS, the small subunit of HHQ dehydrogenase. The presence of the substrate favors electron flow through BtdS, allowing unbinding of RedR2 in an active conformation to induce low expression levels of the enzymes. RedR1 then becomes activated by the pathway intermediate hydroxybenzoquinone. Both regulators are required for maximum pathway expression, suggesting an amplification regulatory cascade is required for coordinate expression of the entire pathway. The structure of the pathway promoters and

regulator binding have been characterized.

## **REGULATION OF CSRA EXPRESSION BY TWO COMPONENT SYSTEMS IN E. COLI**

C. Masson<sup>1</sup>, L. Van Melderens<sup>1</sup>

<sup>1</sup>*Laboratoire de Génétique et Physiologie Bactérienne,  
Free University of Brussels (ULB), Gosselies, Belgium*

### **Background**

Global regulators play major roles in response to a variety of intracellular and extracellular signals, allowing bacteria to adapt to environmental changes.

We are particularly interested in CsrA, a post-transcriptional global regulator acting by binding target mRNAs and thereby modulating translation either negatively or positively.

CsrA is important for cell growth and regulates central carbon metabolism and social behaviors.

Transcriptional regulation of *csrA* expression remains largely unknown although it was shown that Sigma70 and RpoS directly regulate *csrA* expression. At the post-translational level, activity of CsrA is regulated by 2 major sRNAs, *csrB* and *csrC*, which bind CsrA and sequester it away from its targets. Expression of *csrB* and *csrC* is regulated by the BarA/UvrY two-component system.

### **Objectives**

Since CsrA controls pathways that are influenced by environmental conditions, it is likely that *csrA* expression is regulated by two-component systems.

### **Methods**

A screen using *lacZ* transcriptional fusions with the *csrA* promoter was set up to test two-component system mutants. In addition, bioinformatics analysis was performed to determine response regulator binding sites in the *csrA* promoter.

### **Conclusions**

Our results indicate that *csrA* expression is positively regulated by the Cpx two-component system. The Cpx system responds to a broad range of stimuli including pH, salt, lipids and misfolded proteins that cause perturbation in the envelope.

Bioinformatics analysis predicted potential CpxR binding sites in the *csrA* promoter region. EMSA and mutagenesis experiments will be performed to whether Cpx directly regulates *csrA* expression.

#### Background

In bacteria, selective promoter recognition by RNA polymerase is achieved by its association with  $\sigma$  factors, accessory subunits able to direct RNA polymerase “core enzyme” (E) to different promoter sequences.

#### Objectives

The aim of this work was to identify promoters bound by  $E\sigma^S$ , an RNA polymerase form mainly active during slow growth and in response to stress conditions, by using a Chromatin Immunoprecipitation-sequencing (ChIP-seq) approach.

#### Methods

ChIP-seq experiments were performed in a *Escherichia coli* strain carrying a chromosomal  $rpoS_{His6}$  allele grown to stationary phase in rich medium.

#### Conclusions

We identified 78  $E\sigma^S$  binding sites, 63 of which (81%) were located in intergenic regions, mostly overlapping known or putative promoters. The majority of the  $E\sigma^S$ -bound intergenic regions was located upstream of genes (encoding either ORFs or non-coding RNAs) showing some degree of dependence on the  $\sigma^S$ -encoding  $rpoS$  gene. The remaining  $E\sigma^S$ -bound intergenic regions overlapped promoters recognized by RNA polymerase associated with the housekeeping  $\sigma^{70}$  factor, or even with the alternative  $\sigma^E$  and  $\sigma^H$  factors. Transcription of this latter set of genes does not appear to be affected by  $rpoS$  inactivation. Thus, consistent with previous observations, our

results indicate significant overlap in promoter recognition between  $\sigma^S$  and other  $\sigma$  factors.

In particular, our results suggest that, in conditions leading to  $\sigma^S$  accumulation,  $E\sigma^S$  significantly contributes to transcription of genes involved in LPS biosynthesis not belonging to the *rpoS* regulon during transition from exponential to stationary phase.

Finally, our results highlight a direct role of  $E\sigma^S$  in the regulation of non-coding RNAs

Italy*

<sup>2</sup>*FaBiT Department of Pharmacy and Biotechnology, University of Bologna, Bologna,  
Italy*

**Background**

*Helicobacter pylori* is a human pathogen surviving in the prohibitive gastric environment where it can cause cancer. The ability to counteract environmental stresses and host responses is a key feature for persistence and depends on the rapid and fine-tuned expression of the genetic repertoire orchestrated by a shallow Transcriptional Regulatory Network. Metal-dependent regulators NikR and Fur are key hubs in this network; they directly control metal ion homeostasis and indirectly impact on several processes involved in *H. pylori* virulence and survival.

**Objectives**

In this work we combined ChIP- and RNA-sequencing to gain a comprehensive view of the NikR regulome. Moreover we investigated NikR regulation in presence or absence of Ni<sup>2+</sup> in wild-type and in *nikR* or *fur* knock-out strains, aiming to elucidate the plasticity of the system and the level of cooperation and antagonism between these two transcription factors.

**Methods**

For each experimental condition we determined NikR binding regions and defined the link between each binding site and its putative gene/operon target. Then we performed a differential peak calling to classify basal, Ni<sup>2+</sup> driven and Fur coordinated bindings. In parallel differentially expressed genes, operons and ncRNAs were identified. Finally, we discriminated direct and indirect effects of NikR action by integrating ChIP-seq and RNA-seq results.

**Conclusions**

Our study confirms known targets identified through single-gene analysis and sheds light on the entire framework of dynamic interactions between NikR and its regulatory targets, unraveling new explanations for its pivotal function in the persistence and pathogenicity of the bacterium.

**COMPLEMENTATION AND PHENOTYPIC CHARACTERIZATION OF MUTANTS FOR NUCLEOID ASSOCIATE PROTEINS (NAPS) IN SALMONELLA ENTERICA SEROVAR ENTERITIDIS**

C. Carmo<sup>1</sup>, M. Brocchi<sup>1</sup>

<sup>1</sup>*Genetic evolution and bioagents, University of Campinas, Campinas, Brazil*

**Background**

*Salmonella* Enteritidis is the most prevalent serotype in foodborne outbreaks since 1990 associated to poultry meat, eggs and products. The phagotype 4 is among most commonly isolates associated with diarrhea and systemic infection. Due to importance of this pathogen in human and animal health, researchers are searching ways to control *S. enterica* infections using vaccines. Despite the efforts of many groups, a few live vaccine strains are released for use in the salmonellosis control and there are no human vaccines to serovar Enteritidis yet.

**Objectives**

Based on these data, and taking account that motility is an important virulence trait to *Salmonella enterica*, the goal of this study was evaluate the motility phenotype of *S. Enteritidis* PT4 null mutants to genes coding to Naps and their complemented strains in comparison to wild-type strain (WT).

**Methods**

The single mutants to NAPs were constructed by  $\lambda$  Red methodology and the complementation was performed using the cloning vector pACYC184. The motility was determined by measurement of bacteria migration from the center to the periphery of Luria Bertani 0.35% agar plates.

**Conclusions**

The data were analyzed by test-T using the software *Assistat* version 7.7. The *S. Enteritidis* PT4 mutants showed a significant decrease in motility (20-55%) compared to wild-type strain ( $p < 0.01$ ). The complemented mutants reversed the phenotype, presenting motility similar to WT. Thus, we concluded that deletion of these genes affects motility, suggesting that they act directly or indirectly in the regulation of motility-related genes.

<sup>3</sup>Plateforme Intégrée IMAGIF, CNRS, Gif-sur-Yvette, France

<sup>4</sup>UMR1319 Micalis, INRA - AgroParisTech, Jouy-en-Josas, France

**Background**

In the context of the fast development of aquaculture, infections by *Flavobacterium psychrophilum* are a major sanitary concern for the salmonid farming industry worldwide. Juvenile salmonids are particularly susceptible to this Gram-negative aerobic bacterium, which is able to survive outside the fish during long periods of starvation in freshwater environments.

**Objectives**

Transcriptional regulatory networks are crucial for bacteria to maintain their integrity and to adapt to changing growth conditions. Alternative sigma factors confer promoter selectivity by binding to the bacterial RNA polymerase and allow switching between various adaptative responses. How *F. psychrophilum* adapts to environmental conditions has been investigated at the molecular level by analysis of its primary transcriptome and *in silico* prediction of regulons controlled by various sigma factors.

**Methods**

The transcriptional landscape and the transcription start sites (TSS) of the virulent strain THCO2/90 isolated from a Coho salmon, have been established using RNAseq technology by analysing a pool of bacterial RNAs extracted from cells undergoing various growing conditions.

**Conclusions**

Expressed genes as well as putative expression signals and regulatory elements were listed (*i.e.* TSS, 5'-untranslated regions, non-coding and antisense RNAs). *In silico* searches for consensus promoter sequences upstream of identified TSSs revealed more than a thousand sigma-70 dependent promoters as well as three other promoters groups responding likely to alternative sigma factors. Building this detailed transcriptional map represents the first attempt to characterize regulatory networks of *F. psychrophilum*, an important pathogen of the *Bacteroidetes* phylum.

## **PROTEOMIC AND TRANSCRIPTIONAL ANALYSES OF STRESS-RELATED GENES IN BURKHOLDERIA XENOVORANS LB400 DURING OXIDATIVE STRESS**

M. Seeger<sup>1</sup>, V. Mendez<sup>1</sup>, G. Padron<sup>2</sup>

<sup>1</sup>Chemistry, Universidad Tecnica Federico Santa Maria, Valparaiso, Chile

<sup>2</sup>División de Química Física, Centro de Ingeniería Genética y Biotecnología, La Habana, Cuba

### **Background**

*Burkholderia xenovorans* LB400 is a model aromatic compounds-degrading bacterium. Aerobic metabolism of aromatic compounds may produce oxidative stress in bacteria. However, the molecular mechanisms involved are not well known.

### **Objectives**

The aims of this study were to characterize bacterial stress response in *B. xenovorans* LB400 during oxidative stress and aromatic metabolism.

### **Methods**

Stress-related genes were predicted using bioinformatic tools and functional assays were performed by proteomics using high-resolution mass spectrometry and by transcriptomics using qRT-PCR. Oxidizing conditions included exposure of LB400 cells to paraquat and hydrogen peroxide. In addition, transcriptional analysis of stress-related genes from strain LB400 grown on aromatic compounds was performed.

### **Conclusions**

Paraquat induced ferritin DPS-family DNA binding protein (DpsA), alkyl hydroperoxide reductase, fumarase C, catalase, glutathion peroxidase, oxygen peroxide resistance protein (Ohr) proteins. In addition, induction of diverse reducing enzymatic systems such as ferritins and flavodoxins was observed. During hydrogen peroxide exposure, two alkyl hydroperoxide subunits and DpsA protein were induced. A transcriptional analysis indicated that during paraquat and hydrogen peroxide exposure, an up-regulation of *ahpC*, *katE*, *fumC* and *oxyR* genes was observed. During growth of strain LB400 on 3-hydroxyphenylacetate, the expression of *ahpC*, *sod*, *acn*, *fumC* and *oxyR* genes was up-regulated. The expression of *ahpC*, *sod*, and *oxyR* genes were up-regulated during growth on 4-hydroxyphenylacetate. In conclusion, this study illustrated diverse oxidative stress proteins from *B. xenovorans* LB400 that are active during oxidative stress and aromatic compounds degradation.

<sup>2</sup>Molecular Parasitology Proteomic Platform, Free University of Brussels (ULB), Gosselies, Belgium

<sup>3</sup>Molecular Parasitology and CMMI, Free University of Brussels (ULB), Gosselies, Belgium

### **Background**

The CsrA regulatory protein is the main actor of the carbon storage regulator (Csr) network, a well- conserved regulatory network in bacteria. It acts at the post-transcriptional level by binding specific sequences on target mRNAs, thereby modulating gene expression. This global regulator controls several physiological processes, including central carbon metabolism and social behavior. Insights into CsrA roles were mostly obtained with an *E. coli* K-12 *csrA* mutant, encoding a truncated form of CsrA that retains partial activity.

### **Objectives**

This work aims at further characterizing the roles of CsrA by analyzing phenotypes presented by an *E. coli* strain deleted for the *csrA* gene.

### **Methods**

The *csrA* gene was deleted by homologous recombination in the uropathogenic *E. coli* CFT073 strain. Experimental evolution was performed. Three independent evolved mutants were extensively analyzed by combining molecular techniques, microscopy and global approaches, including comparative proteomics and whole genome sequencing.

### **Conclusions**

Deletion of *csrA* leads to severe growth defects and altered cell morphology, indicating that this gene, although not essential, is important for growth. Evolved mutants were rapidly selected (2-3 days of culture in LB medium), showing that deleting the *csrA* gene constitutes a strong selective pressure. Our data confirms that

*csrA* deletion strongly affects central metabolism and energy status. In addition, our data show that specific stress responses are constitutively induced in the deletion mutant, including phosphosugar, oxidative and envelope stress responses. This highlights the interconnection of multiple regulatory networks and their flexibility to compensate for genetic perturbations in *E. coli*.

#### TWO ISOFORMS OF YJJM TRANSCRIPTION FACTOR DIFFERING IN THE DNA-BINDING DOMAIN.

*M. Tutukina*<sup>1</sup>, *U. Shvyreva*<sup>1</sup>, *I. Suvorova*<sup>2</sup>, *J. Cole*<sup>3</sup>, *O. Ozoline*<sup>1</sup>

<sup>1</sup>*Functional genomics and cellular stress, Institute of Cell Biophysics RAS, Pushchino, Russia*

<sup>2</sup>*ESC "Bioinformatics", Institute for Information Transmission Problems RAS, Moscow, Russia*

<sup>3</sup>*School of Biosciences, University of Birmingham, Birmingham, United Kingdom*

#### Background

Ashwell and Entner-Doudoroff pathways provide an alternative to glycolysis being important for bacterial colonization and motility. There are several specific proteins (UxuR, ExuR, UidR and cAMP-CRP) sensing metabolic status of the cell and switching gene expression to the optimal pathway. YjjM was also predicted to be involved in this network.

#### Objectives

The goal of this study was to investigate *yjjM* transcription and modes of regulation.

#### Methods

Alignments and structural predictions were made using BLAST, TCOFFEE and Phyre 2. Promoters were mapped with PlatProm software, single round and 5'-RACE. Expression level was measured by beta-galactosidase assays and qRT-PCR. Proteins specifically bound to the promoter DNA were detected using pull-down assays and mass-spectrometry. YjjM products were identified by Western-blot.

#### Conclusions

YjjM structure is assumed to be very similar to other regulators of the GntR family, with oligomerization/effector binding C-terminal and DNA-binding N-terminal domain. Computational and experimental data indicated that *yjjM* may have two ORFs resulting in synthesis of two proteins variable in their DNA-binding domain by 36 aminoacids. As a basis for this heterogeneity, four possible promoters were mapped nearby the *yjjM* 5'-end, with two of them located within the main ORF. Gene expression analysis, Western-blotting and pull-down assays revealed that regulatory switch from one protein product to another may occur due to the complex interference between RNA-polymerase alpha subunits and transcription factors operating in the *yjjM* regulatory region. Thus in changing growth conditions, different promoters may tune-up DNA-binding properties of YjjM by switching the ratio of its isoforms.

**THE INTEGRATED RESPONSE OF GENOME ORGANIZATION AND ACTIVITY TO ENVIRONMENTAL CUES**

R. van der Valk<sup>1</sup>, J. Vreede<sup>2</sup>, G. Molenaar<sup>1</sup>, N. Goosen<sup>1</sup>, R.T. Dame<sup>1</sup>

<sup>1</sup>*Leiden Institute of Chemistry, Leiden University, Leiden, Netherlands*

<sup>2</sup>*Van 't Hoff Institute for Molecular Sciences, University of Amsterdam, Amsterdam, Netherlands*

**Background**

Loop formation is key to the global organization of genomes in organisms from all three domains of life. Genomes are organized dynamically and their re-modelling is implied in translating external signals into specific gene products. The bacterial chromatin protein H-NS is capable of forming bridges between DNA segments *in vitro* and thus a prime candidate for genomic loop formation *in vivo*. H-NS is also a global regulator of transcription.

**Objectives**

We have investigated how the DNA bridging activity of H-NS is fine-tuned by salt conditions and interaction with co-regulators Hha and YdgT.

**Methods**

We demonstrate, using a combination of biophysical (Tethered Particle Motion), biochemical (*in vitro* bridging assays) and computational (Molecular Dynamics simulations) techniques, that there is a delicate balance between two DNA binding modes ( DNA stiffening and bridging), which can be shifted by environmental cues or H-NS interaction partners.

**Conclusions**

Our observations yield models for fine-tuning of genome organization and for the translation of changes in environmental conditions into transcriptional activity.

## **FEMS-2802**

### **Global regulatory networks**

#### **MALR - THE POSITIVE REGULATOR OF THE MAL OPERON IN THE CRENARCHAEON SULFOLOBUS ACIDOCALDARIUS**

M. Wagner<sup>1</sup>, A. Wagner<sup>1</sup>, X. Ma<sup>2</sup>, S.V. Albers<sup>1</sup>

<sup>1</sup>University of Freiburg, Molecular Biology of Archaea, Germany

<sup>2</sup>Max-Planck-Institute for terrestrial Microbiology, Molecular Biology of Archaea, Germany

**Background** The thermoacidophilic crenarchaeon *Sulfolobus acidocaldarius* can utilize different carbon sources including maltose. In Archaea, sugar uptake is achieved by ABC transporters that are inducible by the corresponding sugars. How these transporters are regulated in Sulfolobales is an open question, since no regulatory proteins have been identified for any sugar ABC transporter so far. The regulation of the maltose uptake and utilization system is of special interest, since this system lies at the basis of the successful inducible expression system in *S. acidocaldarius*.

**Objectives** The aim of this study is to identify and characterize the regulator of the maltose gene cluster in *S. acidocaldarius* and use this knowledge to improve the *S. acidocaldarius* protein expression system

**Methods** The maltose regulator (MalR) of *S. acidocaldarius* was identified based on its sequence similarity to proteins of the TrmB family of regulators. To confirm the role of MalR growth of a deletion mutant was monitored on different carbon sources. Quantitative RT-PCR was used to examine transcription levels of the maltose gene cluster in a maltose-induced or uninduced state. Electromobility shift assays showed that MalR binds the promoter of the maltose binding protein (malE). Improvement of the current protein expression system was achieved by cloning an additional copy of malR into the expression plasmid.

**Conclusion** The maltose regulator of *Sulfolobus acidocaldarius* was identified. It positively controls transcription of the mal operon harboring genes for maltose uptake and metabolism. With the gained knowledge about the maltose regulator we could improve the maltose inducible expression system in *S. acidocaldarius*.

#### RAPID BACILLUS PUMILUS GROUP SPECIES DIFFERENTIATION USING MALDI-TOF-MS AND FTIR-ATR

R. Branquinho<sup>1</sup>, C. Sousa<sup>2</sup>, M. Pintado<sup>3</sup>, H. Osório<sup>4</sup>, L. Peixe<sup>1</sup>

<sup>1</sup>Ciências Biológicas - Laboratório de Microbiologia,

UCIBIO/REQUIMTE - Faculdade de Farmácia Universidade do Porto, Porto, Portugal

<sup>2</sup>CEB – Centro de Engenharia Biológica, Universidade do Minho, Braga, Portugal

<sup>3</sup>CBQF – Centro de Biotecnologia e Química Fina, ESB-

UCP – Escola Superior de Biotecnologia Universidade Católica Portuguesa, Porto, Portugal

<sup>4</sup>IPATIMUP - Instituto de Patologia e Imunologia Molecular, Universidade do Porto, Porto, Portugal

#### Background

*Bacillus pumilus* group members, which encompass the closely related *Bacillus pumilus*, *Bacillus safensis*, *Bacillus altitudinis*, *Bacillus xiamenensis* and the newly described *Bacillus invictae*, possess a high medical, biotechnological and industrial relevance, stressing the need for reliable, easy and rapid methodologies for their correct identification.

#### Objectives

In this study we demonstrated the suitability of Matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF-MS) and Fourier transform infrared spectroscopy with attenuated total reflectance (FTIR-ATR) to accurately and rapidly identify the five closely related species enclosed within *B. pumilus* group, which are difficult to differentiate by conventional and rDNA 16S sequencing methodologies.

#### Methods

MALDI-TOF-MS and FTIR-ATR were applied to discriminate a clonally diverse collection comprising *B. pumilus* (n=5), *B. safensis* (n=19), *B. altitudinis* (n=1), *B. xiamenensis* (n=1) and *B. invictae* (n=5). Snapshots of different protein composition were acquired with a MALDI-TOF/TOF mass spectrometer, operating in linear positive mode, within the ion range at m/z 2000–12000 and using  $\alpha$ -cyano-4-hydroxycinnamic-acid as a matrix. Moreover, the whole-cell content spectra were acquired using a FTIR-ATR System with a PIKE accessory, between 4000 and 400 cm<sup>-1</sup>, with a resolution of 4 cm<sup>-1</sup> and 32 scan co-additions. Both, mass and infrared spectra were analysed by multivariate data analysis.

#### Conclusions

The resulting unique protein profile and the differences gathered in the carbohydrates and phospholipids/DNA/RNA vibration regions obtained by these high throughput approaches, proved that MALDI-TOF-MS and FTIR-ATR are valuable tools for *B. pumilus* group species discrimination, and thus, should be promptly considered for

these species identification.

**ASSESSING THE IMPACT OF TRANSGENIC GRAPEVINE ROOTSTOCKS ON THE ENVIRONMENT USING NGS**

S. DEMANECHÉ<sup>1</sup>, S. Djennane<sup>2</sup>, M. BEUVE<sup>2</sup>, P. SIMONET<sup>1</sup>, O. LEMAIRE<sup>2</sup>

<sup>1</sup>Ampere, Ecole Centrale de Lyon, ECULLY cedex, France

<sup>2</sup>Santé de la Vigne et Qualité du Vin, INRA, COLMAR, France

**Background**

*Grapevine fanleaf virus* (GFLV) is responsible for fanleaf degeneration, which is the most severe virus disease of grapevine worldwide. GFLV causes important economic losses by reducing grape yield, lowering fruit quality, and shortening the longevity of vines. Moreover, with the ban of nematicides and soil disinfectants, fallows over 8 years are the only mean to get rid of the disease in the soil. Amongst the new strategies developed to control fanleaf, genetic engineering to modify the rootstock relying on the concept of pathogen-derived resistance, is the most promising strategy to develop GFLV-resistant grapevines.

**Objectives**

These impact studies aimed to evaluate the potential environmental consequences of the presence of two transgenes (GFLV coat protein gene and *nptII* kanamycin resistance gene) expressed in GM rootstocks, the scion remaining wild-type.

**Methods**

This study was performed in the frame of a French project (ANR IMA-GMO), that will take advantage of next generation sequencing (454 and Illumina MiSeq) technologies and quantitative PCR, to analyze the potential impact of GM plant growth either via expression of transgenes or via possible transgene transfer events (horizontal gene transfer) to microbial populations from a reference soil (Rothamsted Appletree, UK) or a vineyard soil (Bergheim, F), irrespective of the cultivability of these microbes.

**Conclusions**

Preliminary results obtained from confined experiments show no significant major modifications in the structure of the bacterial populations, and no horizontal gene transfer. Our results further stressed the necessity to perform environmental impact evaluation in long-term experiments under real agronomical conditions, in open-field trials.

## **SCREENING FOR SMALL MOLECULE INHIBITORS OF SALMONELLA TYPE III SECRETION**

I. Grin<sup>1</sup>, M. Riess<sup>1</sup>, U. Bilitewski<sup>2</sup>, T. Hesterkamp<sup>2</sup>, M. Brönstrup<sup>2</sup>, S. Wagner<sup>1</sup>

<sup>1</sup>Research Group Prof. Samuel Wagner,

Interfaculty Institute of Microbiology and Infection Medicine Tübingen, Tübingen, Germany

<sup>2</sup>DZIF, Helmholtz Centre for Infection Research, Braunschweig, Germany

### **Background**

Bacterial resistance to currently available antibiotics is becoming increasingly problematic. In the search for novel antimicrobial substances our strategy is to screen for substances which block essential bacterial pathogenicity mechanisms without killing the bacteria.

*Salmonella* is a major cause of food-borne diseases. It relies on two type III secretion systems (T3SS) for host cell invasion and intracellular survival inside the host cells. Selective disruption of these systems would block host cell invasion and leave the bacteria vulnerable to the host immune system.

T3SS are highly conserved across a broad range of Gram-negative bacteria. It is tempting to expect that compounds active against *Salmonella* T3SS will also affect other species such as *Yersinia*, *Shigella* and *Escherichia*.

### **Objectives**

The aim of this project is to develop a screening assay compatible with high-throughput screening and use this assay to screen for anti-virulence compounds against *Salmonella* T3SS.

### **Methods**

We adapted a standard secretion assay to 386-well ELISA format. Bacteria are grown directly in the plates in presence of small molecule compounds. Secreted effectors are adsorbed to the assay plate and subsequently quantified. Various methods for detection and quantification of secreted effectors were evaluated for their sensitivity and robustness.

### **Conclusions**

We have developed a screening approach to search for anti-infective pathogenicity-blocking small molecule compounds, which do not affect bacterial viability. Using this screening assay, we screened multiple compound libraries for active compounds. Potential actives were thoroughly validated in additional assays. In depth testing of the most promising candidates is currently underway.

**INFLUENCE OF COLD AND OSMOTIC STRESS ON TRANSCRIPTION AND TRANSLATION IN ESCHERICHIA COLI O157:H7 SAKAI**

S.M. Huecker<sup>1</sup>, R. Landstorfer<sup>1</sup>, S. Simon<sup>2</sup>, S. Scherer<sup>1</sup>, K. Neuhaus<sup>1</sup>

<sup>1</sup>Chair for Microbial Ecology, TU München, Freising, Germany

<sup>2</sup>Chair for Data Analysis and Visualization Department of Computer and Information Science, Universität Konstanz, Konstanz, Germany

**Background**

The enteric pathogen *Escherichia coli* O157:H7 Sakai (EHEC) expresses different sets of genes dependent on growth conditions. Growth at environmental conditions or in food comprises other challenges than growth in the host. Commonly, transcription intensities are compared between different conditions to obtain information about specific gene regulations. Indeed, changes in transcription levels are informative and have resulted in interesting findings in the past. However, many examples of poor correlation between mRNA and protein level exist due to translational or posttranslational regulation.

**Objectives**

In the past, transcriptomes for defined sets of genes were derived by microarrays. Today, RNAseq allows investigation of complete genomes with wider dynamic range and higher sensitivity compared to the latter technique. In addition, translationally regulated genes can be identified by ribosomal footprinting, where a snap shot of ongoing translation is obtained (translatome).

**Methods**

Strand-specific transcriptomes and translatomes of EHEC were analyzed at two different conditions (control: BHI, 37°C; stress: BHI, 14°C,  $a_w$  0.976) to examine which genes show altered expression and to distinguish transcriptional from translational regulation. For translatome sequencing ribosomal movement is stopped by chloramphenicol, unprotected mRNA is digested by RNases, ribosomes are isolated, and purified mRNA is sequenced.

**Conclusions**

Differences in transcription point, as expected, towards cold and osmotic stress inducible genes. However, the additional translation profiles obtained complete the picture. Examples of translationally regulated genes are presented which do not show changes at the mRNA level, but altered numbers of ribosomal footprints. The regulation might be achieved by, e.g., RNA thermometers.

**High-throughput approaches**

## **HIGH-THROUGHPUT SCREENING OF LACTOBACILLUS SPECIES FOR ANTI-MICROBIAL ACTIVITY COMBINED WITH A COMPARATIVE GENOMIC APPROACH**

R.C. Inglin<sup>1</sup>, L. Meile<sup>1</sup>, M.J.A. Stevens<sup>1</sup>, L. Meile<sup>1</sup>

<sup>1</sup>HEST, Swiss Federal Institute of Technology, Zurich, Switzerland

### **Background**

Lactobacilli are frequently isolated from fermented food-products and are used in starter and protective cultures to control fermentation and avoid spoilage.

### **Objectives**

To identify genes involved in fermentation performance of lactobacilli using broad genotypic/phenotypic screenings with focus on antimicrobial activity.

### **Methods**

A new high-throughput screening technique was developed to rapidly detect antimicrobial activity, using an agar diffusion assay in microtiter plates. All secondary effects like low pH, organic acids or peroxide production were controlled with buffering the media and catalase treatment. Heat and protease treatment were performed to identify bacteriocins. The approach allows screening of test conditions with 10'000 datasets per day, 5'000 antibacterial interactions per day and 3'000 antifungal/antiyeast interactions per day.

We screened 500 Lactobacilli strains from 22 species mainly derived from food environments. A total of 28 conditions were tested including peroxide, bile salt and heat resistance. Further antimicrobial activity was analyzed. We found 65 bacteriocin-like producing candidates and 25 candidates displaying antifungal or antiyeast activity. The antimicrobial activity was diverse and activity against all 12 tested *Enterococcus* strains, all 3 tested *Listeria* species and against *Aspergillus*, *Candida* and *Kluyveromyces* isolates was observed. In a next step pooled DNA samples of active strains were sequenced and comparative genomics performed to identify genes that are responsible for antimicrobial activity and for other tested phenotypes.

### **Conclusions**

The high-throughput methods allow us to screen lactobacilli with minimal laboratory equipment at low costs within short time, bringing phenotypic analyses in pace with next generation sequencing.

**High-throughput approaches**

**UNRAVELING THE PATHWAYS OF AMYLOID TOXICITY IN A BACTERIAL  
MODEL SYSTEM: THE REPA-WH1 PRIONOID**

L. Molina-García<sup>1</sup>, M. Moreno-Del Álamo<sup>1</sup>, R. Giraldo<sup>1</sup>

<sup>1</sup>Cellular and Molecular Biology, (CIB-CSIC), Madrid, Spain

**Background**

Mitochondria are recurrently found to be central in protein amyloidosis. Thus to study mitochondrial physiology in response to protein amyloidosis is a hotspot in the amyloid research field. Since this is a quite challenging task, we have experimentally approached mitochondria in the bacterial model RepA-WH1 prionoid.

We had reported that RepA-WH1, a bacterial protein conformational switch (dWH1/mWH1) functional in plasmid replication, causes an amyloid proteinopathy in *Escherichia coli* hampering cell proliferation. RepA-WH1 aggregates are vertically transmissible but not infectious (horizontally transmissible), and enable conformational templating by cross-seeding *in vitro* and *in vivo*. It is thus the first bacterial prionoid. We have recently found that DnaK, the Hsp70 chaperone in *E.coli*, modulates RepA-WH1 amyloidogenesis *in vivo*.

**Objectives**

Study the pathways of amyloid toxicity of RepA-WH1 combining genomic, proteomic and physiological approaches

**Methods**

We have analyzed through “omics” the gene expression pattern of cells expressing RepA-WH1 (*Affimetrix* microarrays) and the fraction of *E.coli* proteome co-aggregated with RepA-WH1 amyloid inclusions. We have also studied membrane integrity, oxygen consumption rates, iron and ATP levels and sensibility to oxygen reactive species (ROS) in cells expressing RepA-WH1.

**Conclusions**

Our results indicate that cell damage is produced by a ROS-dependent mechanism, most likely involving Fenton chemistry. These findings support a role for free iron in amyloid cyto-toxicity, possibly on top of membrane damage by amyloid oligomers as it has been proposed for general amyloid induced cyto-toxicity in human amyloidosis.

The results presented here underline the power of the bacterial RepA-WH1 prionoid as a synthetic minimalist model system for amyloid proteinopathies.

**FEMS-1813**

## **HIGH-THROUGHPUT SEQUENCING OF BACTERIA ASSOCIATED WITH COMMERCIALY IMPORTANT PELAGIC FISH**

I.S. Roiha<sup>1</sup>, C.S. Svanevik<sup>1</sup>, B.T. Lunestad<sup>1</sup>

<sup>1</sup>Seafood safety and health, National Institute of Nutrition and Seafood Research, Bergen, Norway

### **Background**

As the global demand for fish is increasing, and many marine species are fully exploited, a sustained profit in the industry has to result from improved quality and better utilisation. In Norway, the total volume of captured pelagic fish exceeded 1.1 million metric tonnes in 2013, giving a first-hand value of 730 million USD (4.8 billion NOK), where Atlantic mackerel (*Scomber scombrus*), Atlantic herring (*Clupea harengus*), blue whiting (*Micromesistius poutassou*), and capelin (*Mallotus villosus*) were the most important species. FAO estimates that 10-25 % of all captured fish are lost post-harvest, where microorganisms are of great importance in deterioration of fish products. Currently, bacteria associated with fish are mostly identified by culture-dependent methods. New approaches are needed to understand the complexities of bacterial communities and their influence in fish products, as most bacteria are unculturable.

### **Objectives**

To describe the bacterial community composition of gills, muscle tissue, skin, intestine, and stomach content of pelagic fish. In addition, examine water samples and zooplankton from the area of catch.

### **Methods**

Samples were obtained during commercial catch of important pelagic fish. Bacterial DNA were extracted by DNeasy Blood and Tissue Kit, amplified using NEXTflex 16S Amplicon-Seq Kit, and sequenced by the Illumina platform technology, prior to data processing. Results will be discussed.

### **Conclusions**

The information gathered in this study is important for a better understanding of the microbiology of pelagic fish species. This may again support a reduction of post-harvest losses and increase the profitability of the Norwegian pelagic fish industry.

## **FEMS-2761**

#### **SYNTHETIC BIOLOGY FOR THE DESIGN OF ANTIMICROBIAL PEPTIDES**

S. Schmitt<sup>1</sup>, M. Montalban-Lopez<sup>2</sup>, O.P. Kuipers<sup>2</sup>, D. Peterhoff<sup>3</sup>, R. Wagner<sup>3</sup>,  
S. Panke<sup>1</sup>, M. Held<sup>1</sup>

<sup>1</sup>D-BSSE, ETH Zürich, Basel, Switzerland

<sup>2</sup>Department of Genetics, University of Groningen, Groningen, Netherlands

<sup>3</sup>Institute of Medical Microbiology and Hygiene, University of Regensburg,  
Regensburg, Germany

### **Background**

The number of multi drug resistant pathogens is constantly growing and novel antibiotic substances are desperately needed in order to at least maintain the status quo. Ribosomally synthesized antimicrobial peptides are not yet exploited for human applications despite an indisputable potential. Among those, lantibiotics, a class of posttranslationally modified and thioether-ring bearing antimicrobial peptides, show desirable properties as high but specific antimicrobial activity and excellent stability.

### **Objectives**

We follow a synthetic biology approach for the generation of novel lantibiotics employing the blueprint of natural lantibiotics. Based on their structural and functional features, natural lantibiotics are dissected into modular subunits. These subunits are then shuffled to generate thousands of novel, putative active, chimeric lantibiotics. The lantibiotic genes are subsequently produced by combinatorial DNA *de novo* synthesis. These libraries will then be screened for molecules with high antimicrobial activity.

### **Methods**

To enable for high screening rates we developed a platform based on nL-sized reaction vessels (nL-reactors) that are used for peptide production and activity-screening in a single step and at rates of  $10^5$  variants per day. Library cells are grown to microcolonies within nL-reactors along with a sensor strain. Cells secreting an active antimicrobial peptide will deactivate the sensor cells. Clearance of an nL-reactor from the sensor thus indicates the presence of a strain secreting a highly active peptide.

### **Conclusions**

10<sup>4</sup> different chimeric variants derived from the module-shuffling of ten natural lantibiotics were analyzed. Several interesting antimicrobials have been isolated, demonstrating for the first time the generation of new-to-nature lantibiotics by module-shuffling.

**LACTOCOCCAL SURFACE PROPERTIES AND THEIR ROLE IN MICROBE-MATRIX INTERACTIONS IN DAIRY PRODUCTS**

M. Tarazanova<sup>1</sup>, M. Beerthuyzen<sup>2</sup>, T. Huppertz<sup>3</sup>, M. Wels<sup>4</sup>, J. Kok<sup>5</sup>, H. Bachmann<sup>2</sup>

<sup>1</sup>Molecular Genetics/Health, TIFN/RUG/NIZO food research, Ede, Netherlands

<sup>2</sup>Health, TIFN/NIZO food research, Ede, Netherlands

<sup>3</sup>Texture and Flavor, NIZO food research, Ede, Netherlands

<sup>4</sup>Bioinformatics and Computational Biology, TIFN/NIZO food research, Ede, Netherlands

<sup>5</sup>Molecular Genetics, University of Groningen, Groningen, Netherlands

**Background**

Microbial surface properties are highly variable and they are considered to be important for the interactions of the bacterial cell with the product matrix. Lactic acid bacteria are industrially used for the fermentation of milk to produce, e.g., yoghurt or cheese. In fresh milk, bacteria encounter particles such as casein micelles or fat droplets, while in fermented milk products, the proteins form a semi-solid casein matrix, in which fat globules and whey pockets are present. However, the extent to which the interaction of dairy starter cultures with the various matrix components is important for the result of fermentations is largely unknown.

**Objectives**

To which extent do bacterial cell surface properties influence interactions with the matrix in a fermented dairy product? Does it impact on starter functionality and what are the underlying mechanisms?

**Methods**

ZetaSizer was used to measure cell surface charge, microbial adhesion to Hydrocarbons (MATH) method - to measure surface hydrophobicity, and Flow Cytometry - to measure cell attachments to milk proteins.

**Conclusions**

Here, we analyzed the surface properties of 55 *L. lactis* strains and found big variations in bacterial cell-charge, surface hydrophobicity and cell attachment to milk proteins. As we also have the full genome sequences of these 55 strains, genotype - phenotype matching was used to identify mechanisms involved in the described surface properties. The identified properties and mechanisms and their relevance in relation to microbe-matrix interactions will be discussed.

**IS THE PREVALENCE OF CYCLOSPORA CAYETANENSIS IN HIV INFECTION UNDERESTIMATED?**

H. Kırkoyun Uysal<sup>1</sup>, S. Altıparmak<sup>1</sup>, T. Yıldırım<sup>2</sup>, F. Simsek<sup>2</sup>, A. Kantürk<sup>2</sup>, O. Akgül<sup>3</sup>, Y.A. Öner<sup>1</sup>

<sup>1</sup>Medical Microbiology, Istanbul University Istanbul Faculty of Medicine, Istanbul, Turkey

<sup>2</sup>Infectious Disease and Clinical Microbiology, Okmeydani Training and Research Hospital, Istanbul, Turkey

<sup>3</sup>Vocational School of Health Services, Üsküdar University, Istanbul, Turkey

**Objectives:** Cyclosporiasis can occur as a locally-acquired infection, among travelers or in patients with HIV/AIDS. In our country, the prevalence of *Cyclospora cayetanensis* are not clear, and researches about this microorganism in HIV infected individuals are limited. The aim of this study was to determine prevalence of *Cyclospora cayetanensis* in symptomatic and asymptomatic HIV infected individuals with conventional and molecular methods.

**Methods:** One-hundred stool samples of HIV infected individuals were included in this prospective clinical study. The stool samples were investigated by modified Ziehl-Neelsen staining and Real-Time Polymerase Chain Reaction (PCR) methods to determine the existence of *Cyclospora cayetanensis*. Permission to conduct this study was obtained from the local ethics committee of Istanbul University Istanbul Medical Faculty, Turkey.

**Results:** *Cyclospora cayetanensis* was found positive by Real-Time PCR in two samples (%2), and in one sample was found positive by modified Ziehl-Neelsen staining (%1).

**Conclusions:** As cyclosporiasis is an endemic disease in our country, *Cyclospora cayetanensis* should be considered in clinical cases, especially in immunocompromised or have long-term diarrhoea patients. In terms of cyclosporiasis, laboratory request would be appropriate in not only immunocompromised patients but also have a healthy immunity individuals. Also, patients with a history of overseas trips to endemic areas, a history of recurrent or long-term diarrhoea and abdominal pain complaints might be examined for *Cyclospora cayetanensis*. The use of Real-Time PCR seems logical, faster, efficient and more sensitive method for the laboratory diagnosis of *Cyclospora cayetanensis* according to microscopic methods in our study.

## **EVOLUTION AND PHYLOGENY OF PHYTOPLASMA ASSOCIATED WITH LEMON WITCHES' BROOM AS A FIRST RECORD FROM EGYPT**

N. Aref<sup>1</sup>, M. Mahrous<sup>2</sup>, A. El-Attar<sup>3</sup>

<sup>1</sup>*Departement of Botany and Microbiology, College of Science King Saud University, Riyadh, Saudi Arabia*

<sup>2</sup>*College of Health Science, Saudi Electronic University, Riyadh, Saudi Arabia*

<sup>3</sup>*Agricultural Research Center (ARC), Plant Pathology Research Institute, Giza, Egypt*

### **Background**

Witches' broom disease (WB) is a serious disease of acid limes. The first report of the disease was in Oman more than 30 years ago and has since spread to the United Arab Emirates, Iran and India where the destruction of 98% of lime trees occurred and has become a major limiting factor for lime production

### **Objectives**

The application of nested-PCR assays, the use of conserved sequences and sequencing the new emerged strains allow to broadly detect the evolution and virulent strains in field.

### **Methods**

Symptoms of the Phytoplasma Associated with (WB) infection were observed on limes for the first time in Egypt. The disease was biologically characterized. Cytopathological detection referred to Diene's stain was used to differentiate the phloem tissues of leaf sections from infected trees. Transmission Electron Microscopy (TEM) indicated the presence of phytoplasmas and were detected by the specific amplification of their 16S-23S rRNA gene. Polymerase chain reaction (PCR), utilizing the universal phytoplasma-specific primers (P1/P7 followed by R16F2n/R16R2). The amplified PCR fragment of 16S rRNA gene was successfully cloned and sequenced. The nucleotide sequences were published to the GenBank with accession number "KJ948653" and named as Lemon Witches' broom-Egyptian strain (LWB-Eg strain). Phylogenetic analysis was performed to identify the LWB-Eg strain through the alignment with the corresponding phytoplasma strains available in the GenBank

### **Conclusions**

This study discovered and identified the phytoplasma strain of LWB-Eg *Candidatus Phytoplasma aurantifolia* as a natural evolved causal agent from Lime WB strain from Oman (EF186828, 16SrII) which induces severe Witches' broom epidemic disease on lemon in Egypt.

## **ENTEROCOCCUS FAECIUM GENOME DYNAMICS IN LONG-TERM PATIENT GUT COLONIZATION**

J. Baan<sup>1</sup>, J. Bayjanov<sup>1</sup>, M. Watson<sup>2</sup>, R.J.L. Willems<sup>1</sup>, W. van Schaik<sup>1</sup>

<sup>1</sup>Department of Medical Microbiology, University Medical Center Utrecht, Utrecht, Netherlands

<sup>2</sup>Edinburgh Genomics The Roslin Institute and R(D)SVS, University of Edinburgh, Edinburgh, United Kingdom

### **Background**

Since the mid-1980s *Enterococcus faecium*, normally a harmless gut commensal, has emerged as an important nosocomial pathogen that has acquired multiple antibiotic resistances. Patients can be colonized with multidrug-resistant *E. faecium* during hospitalization. These bacteria can remain present in the intestinal tract for a long period of time after hospital discharge.

### **Objectives**

Our aim is to analyze the genome dynamics of multi drug-resistant *E. faecium* isolates that colonized the gut of patients over a large timespan.

### **Methods**

The genomes of 96 isolates obtained over 8 years from 5 different patients were sequenced. We generated a core genome-based phylogenetic tree with these genomes, together with 70 previously published *E. faecium* genomes of diverse origins. Furthermore, we investigated highly similar subsets of patient isolates to describe micro-evolution in closely related strains.

### **Conclusions**

Whereas some patients were colonized for almost 2 years with a clonal population of *E. faecium*, other patients were colonized by a diverse population of *E. faecium* strains. Almost all isolates could be assigned to a hospital-associated sub-population of *E. faecium*. By studying the pan-genome of the strains in this patient isolate dataset, we identified gene gain and gene loss events. We also found evidence for recombination events, and for transmission of *E. faecium* strains between patients during hospitalization. This study highlights the different mechanisms that contribute to the genomic flexibility of clinical *E. faecium* strains. This may be a crucial factor in the ability of *E. faecium* to rapidly adapt to new ecological niches.

Germany

<sup>4</sup>Proteomics, INBIOTEC (Instituto de Biotecnología de León), León, Spain

<sup>5</sup>Pilot Plant, INBIOTEC (Instituto de Biotecnología de León), León, Spain

**Background**

*Corynebacterium glutamicum* is a well-known amino acid producer microorganism. L-glutamic acid and L-lysine have become bulk products inside an opened worldwide market to threonine or tryptophan. Thus, the portfolio of *Corynebacterium* has been enlarged by relevant bioproducts such as biodegradable polymers and ingredients or additives in food, feed, cosmetics and pharmaceuticals. This new compounds production has been eased by the huge knowledge accumulated along the last decades in *C. glutamicum*, as well as the introduction of the genome sequencing facilities and other omics methodologies.

**Objectives**

The release of more than twelve genome sequences of *C. glutamicum* allows the location of their genes, putative pseudogenes, transposones or pro-phage sequences. These data have permitted the selection of putative dispensable genes or genome regions. However, the recent studies on small RNA (sRNA) or the description of Actinobacteria cryptic secondary metabolite biosynthetic gene clusters have forced to review the idea of 'dispensable regions'.

**Methods**

A meticulous RNAseq study of *C. glutamicum* transcriptome combined with bioinformatic analyses have allowed the update of the genome organization and the identification of confirmed intergenic regions free of possible genetic elements (sRNA, terminators and extended operons).

**Conclusions**

Consequently, a pool of these intergenic regions suitable for the integration of heterologous or homologous genes has been defined in *C. glutamicum*. In addition, several genes that enhance the oxygen uptake, primary metabolism precursors supply or the translation activity have been used to test the best region candidates. A set of validated *C. glutamicum* intergenic regions have been defined for genetic engineering applications.

## **SIMILARITIES AMONG PSYCHROTOLERANT BACILLUS CEREUS SENSU LATO GROUP MEMBERS SUGGEST THEIR COMMON EVOLUTIONARY HISTORY**

M. Bartoszewicz<sup>1</sup>, U. Czyżewska<sup>2</sup>

<sup>1</sup>Department of Microbiology, University of Białystok, Białystok, Poland

<sup>2</sup>Department of Cytobiochemistry, University of Białystok, Białystok, Poland

### **Background**

The *Bacillus cereus* group comprises seven bacterial species with different ecological properties and impact on human activity. Besides virulence and heat-resistance of spores, these bacteria often show psychrotolerance, being a serious problem in food processing. Until now, cold adapted bacilli were noted among isolates representing different taxa of the entire group, however precise relationships between them remain unknown.

### **Objectives**

We decided to investigate (i) the frequency of psychrotolerant *B. cereus* group members, (ii) assess their enterotoxigenicity, (iii) genetic diversity and (iv) relationships between cold adapted isolates in the context of their origin.

### **Methods**

*B. cereus* group strains (N=400) were PCR screened for the presence of the psychrotolerant form of the *cspA* gene and cultivated at 7°C to identify cold-adapted bacteria. Enterotoxigenicity was assessed by PCR technique and immunochromatographic Duopath Cereus tests. Next, 16S rRNA gene sequencing and MLST typing were applied to establish diversity and genetic relationships among tested strains. Dendrograms were constructed using NJ method in Mega 5 software and index of association was calculated using START 2 software.

### **Conclusions**

Psychrotolerant isolates were found among *B. cereus*, *B. weihenstephanensis*, *B. mycoides* and *B. thuringiensis* from range of habitats in different frequency. They form one homogenous group in opposition to polymorphic mesophilic isolates, probably due to the slower multiplication and stabilizing effect of natural selection. Similarities in sequences of chromosomal genes and diversity of plasmid-borne features suggest that all the cold-adapted strains may have common evolutionary history.

## **GENOME COMPARISONS REVEAL THE EVOLUTION OF NITROGEN FIXATION IN BURKHOLDERIA**

W.Y. Chan<sup>1</sup>, E.T. Steenkamp<sup>1</sup>, J. Vorster<sup>2</sup>, O. Reva<sup>3</sup>, S.N. Venter<sup>1</sup>

<sup>1</sup>Department of Microbiology and Plant Pathology, University of Pretoria, Pretoria, South Africa

<sup>2</sup>Department of Plant Production and Soil Science, University of Pretoria, Pretoria, South Africa

<sup>3</sup>Department of Biochemistry, University of Pretoria, Pretoria, South Africa

### **Background**

The genus *Burkholderia* includes various rhizobial species capable of establishing nitrogen-fixing symbioses with certain legumes. The ability to biologically fix atmospheric nitrogen is conferred by the bacterial partner and may be transferred horizontally between species. Previous work suggests a unique evolutionary origin for the nitrogen fixing abilities of South African rhizobial species of *Burkholderia*.

### **Objectives**

In this study we investigated the evolutionary history of the nitrogen fixation loci in South African *Burkholderia* bacteria with rhizobial properties by making use of genome data.

### **Methods**

The publically available genomes of 16 *Burkholderia* species were used in this study. These included 4 South African rhizobia, 8 rhizobial species from other parts of the world, as well as 4 diazotrophic members of the genus. We also determined the genomes sequences for an additional three rhizobial species of *Burkholderia* from South Africa. The nitrogen fixation locus of these bacteria were identified and characterized, after which synteny was investigated and phylogenetic histories determined.

### **Conclusions**

Genome comparisons revealed three distinct structures for the nitrogen fixation locus among the 19 bacteria examined. One of these was represented by the South Africa species, while the other two were respectively represented by the diazotrophs and the rhizobial species from other parts of the world. Phylogenetic analyses suggested distinct evolutionary origins for the three types of nitrogen fixation locus. Overall, our

data indicated that horizontal gene transfer, gene rearrangement and/or gene replacement contributed to the differences observed in the architecture of the nitrogen fixation loci within the genus *Burkholderia*.

## **COMPARATIVE ANALYSIS OF THE GENOMES OF THE BACTERIA PANTOEA ANANATIS AND PANTOEA AGGLOMERANS**

O. Choi<sup>1</sup>, I. Hwang<sup>2</sup>, J. Kim<sup>3</sup>

<sup>1</sup>*Division of Applied Life Science (BK21Plus), Gyeongsang National University, Jinju, Korea*

<sup>2</sup>*Department of Agricultural Biotechnology, Seoul National University, Seoul, Korea*

<sup>3</sup>*Division of Applied Life Science (BK21Plus) Institute of Agriculture & Life Science, Gyeongsang National University, Jinju, Korea*

### **Background**

*Pantoea ananatis* causes diverse plant diseases, including fruit rot of pineapple, leaf blight of eucalyptus, brown stalk rot of maize, center rot of onion, and sheath rot of rice. This bacterium is also known as an opportunist human pathogen. *Pantoea agglomerans* causes bacteria palea browning of rice.

### **Objectives**

In the present study, the sequenced genomes of the closely related bacteria *P. ananatis* and *P. agglomerans* were compared with emphasis on genome organization and coding capacity.

### **Methods**

Whole genome DNA sequencing of bacteria was performed using Illumina sequencing via the synthesis method on an Illumina HiSeq 2000 genome analyzer.

### **Conclusions**

The genomes of *P. ananatis* strain PA13 from diseased grains of rice, and strain HY02 from onion center rot consist of a single circular chromosome consisting of ~4.58 Mb and a circular plasmid (~0.28 Mb). The genome of *P. agglomerans* strain SW2 consists of a single circular chromosome consisting of 3.95 Mb and three circular plasmids, Pagg\_1p (0.42 Mb), Pagg\_2p (0.16 Mb), and Pagg\_3p (94 Kb). Short collinear regions, which are identical to DNA sequences in the *Escherichia coli* MG1655 chromosome, were widely dispersed along the *Pantoea* genomes. The genome information and the mutant library will allow a better understanding of how *Pantoea* causes diseases on their plant hosts and can be utilized to develop effective control methods against these important plant pathogens.

**ANALYSIS OF METHYLOTROPHIC METABOLISM OF PARACOCCLUS AMINOVORANS JCM 7685 (ALPHAPROTEOBACTERIA)**

J. Czarnecki<sup>1</sup>, M. Puzyna<sup>1</sup>, E. Prochwicz<sup>1</sup>, D. Bartosik<sup>1</sup>

<sup>1</sup>Department of Bacterial Genetics, University of Warsaw, Warsaw, Poland

**Background**

*Paracoccus aminovorans* JCM 7685 (*Alphaproteobacteria*) is a facultative methylotroph, which utilizes a wide range of C1 compounds, including methanol, methylated amines and *N,N*-dimethylformamide. Whole genome sequencing and sequence analysis revealed that the strain contains several genetic modules presumably involved in methylotrophy. Interestingly, many of these modules are unique among bacteria of the genus *Paracoccus* spp.

**Objectives**

The identified genes, predicted to be involved in C1 metabolism, show only moderate similarity to the corresponding genes of other well-known methylotrophs. Therefore, we conducted a set of experiments to confirm their functions and to analyze their regulation.

**Methods**

The mutant strains of *P. aminovorans* were constructed with application of transposon mutagenesis and gene replacement strategy. Proteins upregulated during methylotrophic growth were identified by the comparison of protein profiles of the bacteria grown on various C1 compounds (SDS-PAGE), followed by mass spectroscopy of selected protein bands. Activities of promoters were studied under methylotrophic and non-methylotrophic conditions using  $\beta$ -galactosidase assay.

**Conclusions**

Methylotrophic metabolism of *P. aminovorans* differs highly from that of the closely related, well-studied methylotroph *P. denitrificans* (type strain of the genus *Paracoccus*). The studied strain encodes not only more enzymes enabling oxidation of wider range of C1 compounds but has also completely different central metabolism of C1 subunit assimilation (the serine cycle in *P. aminovorans* vs. the Calvin cycle in *P. denitrificans*). Almost all genes activated during methylotrophic growth are encoded within large extrachromosomal replicons (chromids pAMV1 and pAMV3). Therefore it is highly probable that these genes might have been horizontally acquired, building mosaic methylotrophy pathways.

## **CHARACTERISATION OF PROPIONIBACTERIUM FREUDENREICHII THROUGH COMPARATIVE GENOMICS**

*P. Deptula*<sup>1</sup>, P.K. Laine<sup>2</sup>, P. Koskinen<sup>2</sup>, O.P. Smolander<sup>2</sup>, L. Paulin<sup>2</sup>, V. Piironen<sup>1</sup>, K. Savijoki<sup>1</sup>, P. Auviner<sup>2</sup>, P. Varmanen<sup>1</sup>

<sup>1</sup>Department of Food and Environmental Sciences, University of Helsinki, Helsinki, Finland

<sup>2</sup>DNA sequencing and Genomics Laboratory, University of Helsinki, Helsinki, Finland

### **Background**

*Propionibacterium freudenreichii* is an industrially important bacterium recognised for its well-documented role in ripening of Swiss-type cheeses, production of active form of vitamin B<sub>12</sub>, capability to produce considerable amounts of propionate as well as for its recently acknowledged probiotic potential. Moreover, this species is characterized by hardiness and ability to adapt to various conditions such as those encountered in dairy and cereal environments. To this date only one genome sequence of *P. freudenreichii* has been published, hindering the possibility to fully explore its potential. *P. freudenreichii* is characterized by high G+C content and regions of repeated sequences, which has been an obstacle in unraveling the genomes of this species using Next Generation Sequencing methods such as Illumina and 454.

### **Objectives**

In this project we sequenced twenty-five genomes of *Propionibacteria* associated with various environments to identify pathways contributing to adaptation and to industrially important traits of *Propionibacterium freudenreichii*.

### **Methods**

The PacBio RSII sequencing technology was used as the method of choice, since it enables genomic library preparation without PCR amplification, and produces long reads (~10kbp) allowing for complete coverage of regions with repeated sequences. Genomes were annotated and analysed with various bioinformatic tools.

### **Conclusions**

Whole genome sequencing of *P. freudenreichii* is feasible with the PacBio RSII method and the produced genomes will help to elucidate the true potential of the species.

**OLSG (SINAC\_1600) IS AN ORNITHINE LIPID N-METHYLTRANSFERASE FROM THE PLANCTOMYCETE SINGULISPHAERA ACIDIPHILA**

W. Escobedo-Hinojosa<sup>1</sup>, M.A. Vences-Guzmán<sup>1</sup>, F. Schubotz<sup>2</sup>, M. Sandoval-Calderón<sup>1</sup>, R.E. Summons<sup>2</sup>, I.M. López-Lara<sup>1</sup>, O. Geiger<sup>1</sup>, C. Sohlenkamp<sup>1</sup>

<sup>1</sup>Genomic Ecology, Center for Genomic Sciences, Cuernavaca Morelos, Mexico

<sup>2</sup>Earth Atmospheric and Planetary Sciences, Massachusetts Institute of Technology, Cambridge MA, USA

**Background**

Ornithine-lipids (**OLs**) are prokaryote-specific phosphorus-free membrane lipids. A function for **OLs** in stress conditions and in host-bacteria interactions, either symbiotic or pathogenic, has been shown in some bacteria. A variety of hydroxylations in different structural positions and its stress resistance implications have been reported. Recently, for the first time the presence of *N*-methylated **OL** derivatives had been described in the planctomycete *Singulisphaera acidiphila*. However, the gene/enzyme responsible for the methylation in *S. acidiphila* remained elusive.

**Objectives**

Identify and characterize the novel **OL-N**-methyltransferase **OlsG** from *S. acidiphila*.

**Methods**

We identified twelve candidate genes from *S. acidiphila* encoding enzymes possibly responsible for methylated **OL** synthesis. Recently, our group identified the **OL** synthase **OlsF** from *S. proteamaculans* that upon expression in *E. coli* caused **OL** formation, so the twelve candidate genes were expressed one by one in this **OL**-forming *E. coli* strain and we analyzed the lipid composition of [<sup>14</sup>C]acetate labeled cultures of the resulting strains by two-dimensional thin-layer chromatography, leading to the identification of the novel methyltransferase **OlsG**, also confirmed by mass-spectrometry.

*In vitro* characterization shows that **OlsG** is responsible for the threefold **OL** methylation, resulting in monomethyl-**OL** (**MMOL**), dimethyl-**OL** (**DMOL**), and trimethyl-**OL** (**TMOL**). Time-dependency of **OL-N**-methyltransferase activity was observed.

**OlsG** contains 192 amino acids, is soluble, requires *S*-adenosylmethionine (SAM). Maximal *N*-methyltransferase activity was observed at pH=8 and in presence of

TritonX-100 [0.03-0.05%(w/v)].

## Conclusions

**OlsG** is responsible for a new type of **OL** modification.

**OlsG** is the first **OL-N**-methyltransferase described.

**GENOMIC ANALYSIS OF SPHINGOPYXIS (FORMERLY SPHINGOMONAS)  
MACROGOLTABIDA STRAIN TFA REVEALS NEW INSIGHTS FOR  
SPHINGOPYXIS GENUS**

I. García-Romero<sup>1</sup>, Y. González-Flores<sup>1</sup>, A. Pérez-Pulido<sup>1</sup>, E. Santero<sup>1</sup>, F. Reyes<sup>1</sup>,  
B. Floriano<sup>1</sup>

<sup>1</sup>Department of Molecular Biology and Biochemical Engineering,  
CABD (Andalusian Centre for Developmental Biology) CSIC-UPO-JA, Seville, Spain

**Background**

TFA is a gram negative bacterium able to grow on tetralin as the sole carbon and energy source. Based on a partial 16S sequence it was initially ascribed to the *Sphingomonas* genus. Despite the exhaustive study of the tetralin degradation pathway, other genomic and metabolic characteristics of TFA remain unknown.

**Objectives**

The main objective is to establish the TFA metabolic map using a genomic approach and further experimental validation. New metabolic features are being experimentally validated.

**Methods**

Contigs resulting from the sequencing process were assembled. Prodigal software was used to predict protein-encoding genes, which were functionally annotated by Sma3s. The final annotation was analyzed with Pathway Tools software to generate a preliminary metabolic network. This analysis was complemented with antibiotics and secondary metabolites clusters prediction with antiSMASH. CMG-biotools, BRIG and IslandViewer were employed in comparative genomic analysis.

**Conclusions**

TFA has been re-assigned to the *Sphingopyxis* genus based on reciprocal identity comparisons versus members of the *Sphingomonadaceae* family. Highly similar regions between TFA genome and other  $\alpha$ -proteobacteria have been detected. Despite no plasmids have been detected, plasmid-related genes have been annotated, suggesting the importance of horizontal transfer in the construction of TFA genome. Comparative genomic predicts 914 TFA genes absent in other *Sphingopyxis*. A complete *nar* genes cluster encoding a membrane-bound respiratory nitrate reductase and genes for cobalamin biosynthesis seem to be exclusive characteristics of TFA.

Anaerobic growth reducing nitrate has not been described in *Sphingomonadaceae* family before. Preliminary metabolic reconstruction suggests that TFA might be able to degrade other aromatic compounds.

D.G. Alexeev<sup>2</sup>, E.A. Bonch-Osmolovskaya<sup>1</sup>, I.V. Kublanov<sup>1</sup>

<sup>1</sup>Laboratory of Hyperthermophilic Microbial Communities,  
Winogradsky Institute of Microbiology RAS, Moscow, Russia

<sup>2</sup>Laboratory of Bioinformatics, Research Institute of Physico-Chemical Medicine,  
Moscow, Russia

### Background

Ignavibacteria are phylogenetically closely related to Chlorobi but essentially differ from them by their facultatively anaerobic mode of metabolism and obligate organotrophy. *Melioribacter roseus* is one of the two cultured representatives of Ignavibacteriae which grows either by fermentation of sugars and peptides, aerobic respiration or dissimilatory reduction of arsenate, nitrite or Fe(III). Genome analysis highlighted key determinants of respiratory metabolism in *M. roseus* and provided insights into its adaptation to fluctuating environmental conditions. Full set of proton-translocating membrane complexes and several putative terminal oxidoreductases were identified in the *M. roseus* genome.

### Objectives

We aimed at experimental evaluation of the role of these enzymes in energy metabolism of the organism and deciphering the mechanisms for aerobic and anaerobic respiration, basing on profound genomic analysis and experimental data.

### Methods

Inhibitor analysis and direct membrane potential measurements were used to reveal the activity of electron transfer chain in the organism. Phylogenetic analyses of the catalytic subunits of revealed oxidoreductases, transcriptomic and proteomic studies were used to confirm the function of predicted oxidoreductases in *M. roseus* metabolism.

### Conclusions

Activity of electron transfer chain under aerobic or Fe(III) respiration was revealed. Key role of a novel *cc(o/b)<sub>3</sub>*-type cytochrome oxidase and ACIII complex in aerobic respiration as well as the involvement of two non-Arr molybdopterin oxidoreductases and putative porin-cytochrome complex in anaerobic respiration were identified. Our results provide the basis for the reconstruction of the evolution of aerobic and anaerobic respiratory pathways in Chlorobi-Bacteroidetes-Ignavibacteriae group and expand the knowledge base on the novel phylum Ignavibacteriae.

B.C.A. Cabral<sup>1</sup>, T.P. Ürményi<sup>1</sup>, S.M.F.O. Azevedo<sup>1</sup>, R. Silva<sup>1</sup>

<sup>1</sup>Instituto de Biofísica Carlos Chagas Filho, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil

**Background**

Aquatic systems are in constant transformations for the accelerated artificial eutrophication process that means nutrients enrichment. The artificial Paranoá Lake, located in Brasília (Federal District), yet in constant eutrophication process, supplies a higher degree of humidity to the local dried atmosphere. The Funil reservoir, an eutrophic environment located in Resende (Rio de Janeiro), was constructed to normalize the flow of the Paraíba do Sul River and to attenuate the impact of floods. Blooms of cyanobacteria are being reported for both aquatic ecosystems.

**Objectives**

The aim of this work is to obtain the complete genome of two cyanobacteria strains previously classified as: CYLP, non-toxic, isolated from Paranoá Lake; and CYRF, a toxic strain, isolated from Funil Reservoir; and to assess the fundamental genetic differences between the strains.

**Methods**

A next generation sequencing protocol was performed to run in Ion PGM™ platform. DNA fragments size of 400 bp from both CYLP and CYRF strains were prepared and sequencing runs were performed. Reads were downloaded from Ion Server and trimmed (quality/size) using CLC Genomics Workbench v7.5, resulting in 709Mb for CYLP and 867Mb for CYRF. The best hit species from BLASTN results was against to *Cylindrospermopsis raciborskii*. So, reads were mapped against the reference sequence CS-505 (ACYA01000000). Reads were assembled to contigs using MIRA and the final assembly was performed using CONTIGuator.

**Conclusions**

Two strains with different toxicities isolated from two Brazilian aquatic ecosystems were successfully sequenced. The assembly generated about 50 contigs. Functional analysis is being performed.

**Background**

The microbial communities in the small intestine rely on their capacity to rapidly import and ferment available carbohydrates to survive in a complex and highly competitive ecosystem.

**Objectives**

Understanding how these communities function requires elucidating the role of its key players and the interactions among them and with their environment/host. Hence, we present the complete genome of *Romboutsia ilealis* CRIB<sup>T</sup>, a natural inhabitant and key player of the small intestine of rats.

**Methods**

The complete genome of *R. ilealis* CRIB<sup>T</sup> was sequenced and annotated, followed by a whole-genome transcriptome analysis after growth on specific carbohydrates (glucose, L-fucose and fructo-oligosaccharide [scFos]).

**Conclusions**

*R. ilealis* CRIB<sup>T</sup> possesses a circular chromosome of 2,581,778 bp and a plasmid of 6,145 bp, carrying 2351 and eight predicted protein coding sequences, respectively. Analysis of the genome reveals only limited coding capacity to synthesize amino acids and vitamins. However, multiple and partially redundant pathways for the utilization of different relatively simple carbohydrates are present in the genome. The transcriptome analysis allows pinpointing the key components in the degradation of glucose, L-fucose and fructo-oligosaccharides. This reveals that *R. ilealis* CRIB<sup>T</sup> is adapted to a nutrient-rich environment where carbohydrates, amino acids and

vitamins are abundantly available. This work shows how genome mining and functional analyses with single microbes can provide an insight in the functional potential of new members of the intestinal microbiota, and will help us with understanding the microbial communities **in us**.

## **MLST TO RESOLVE DISCREPANCIES IN THE IDENTIFICATION OF CRONOBACTER SPECIES**

E.E. Jackson<sup>1</sup>, S.J. Forsythe<sup>1</sup>

<sup>1</sup>*School of Science and Technology, Nottingham Trent University, Nottingham, United Kingdom*

### **Background**

Differentiation of closely related species, such as those in the *Cronobacter* genus can be difficult. Previous characterization of *Cronobacter* isolates by phenotyping, ribotyping and 16S rRNA sequencing revealed discrepancies in the identification of certain strains (1).

### **Objectives**

This study used multilocus sequence typing (MLST) to resolve these discrepancies in the identification of *Cronobacter* species.

### **Methods**

MLST analysis was performed as previously described (2). Species identifications based on MLST were compared to previously reported phenotyping, ribotyping and 16S rRNA sequencing results (1).

### **Conclusions**

MLST confirmed ribotyping and 16S rRNA sequencing results by identifying strain 05CHPL02 as *C. dublinensis* and strain 05CHPL53 as *C. sakazakii*. These strains were misidentified biochemically. Strains 05CHPL46 and 07HMPA87A were identified as *C. malonaticus*, confirming the phenotyping and ribotyping results. Both strains were misidentified as *C. sakazakii* by 16S rRNA sequencing, likely due to the close relationship of these two species. The identification of strain 05CHPL65 as *C. sakazakii* by phenotyping and ribotyping was confirmed by MLST, though it was misidentified by 16S rRNA sequencing. Finally, strain 05CHPL47 was identified as *C. malonaticus* by MLST, whereas the other methods identified it as *C. sakazakii*.

Phenotyping, ribotyping and 16S rRNA sequencing limited in their use for the identification of *Cronobacter* spp. DNA sequence-based methods, such as MLST, are much more reliable for the identification of *Cronobacter* isolates.

### **IS THE RIBOSOME TARGETED BY ADAPTIVE MUTATIONS?**

A. Jiménez Fernández<sup>1</sup>, L.R. Jensen<sup>1</sup>, H.K. Johansen<sup>1</sup>, S. Molin<sup>1</sup>

<sup>1</sup>*Biosustain, Danmarks Tekniske Universitet (DTU), Hørsholm, Denmark*

#### **Background**

RNA polymerase and ribosomes, composing the macromolecular synthesis machinery (MMSM), carry out the central processes of transcription and translation, but are usually seen as mechanical elements with no regulatory function. Extensive investigations of gene regulation and the high degree of evolutionary conservation of the cellular MMSM tend to support this view. However, under certain selective conditions the machinery itself may be targeted by adaptive mutations, which result in fitness increasing phenotypic changes. Here we investigate and characterise the role of ribosomal mutations in adaptive evolution.

#### **Objectives**

To elucidate the consequences of mutations in ribosomal protein genes in infecting bacterial isolates from human lungs.

#### **Methods**

Several mutations in ribosomal genes have been identified in the genome analysis of nearly 700 *P. aeruginosa* isolates from infected cystic fibrosis patients. Among these mutations we have repeatedly identified insertions, deletions and substitutions in specific ribosomal genes. Preliminary assays show that mutant strains have reduced growth rate and an altered antibiotic resistance pattern. The selection for mutations in ribosomal protein genes is partly explainable by the antibiotic treatment of the patient. But other mutations cannot be directly associated with antibiotic resistance. The bacterial phenotypes of the mutated strains will be investigated.

#### **Conclusions**

Clarification of the potential pleiotropic consequences of the specific mutations in ribosomal proteins is important for our understanding of biological evolution, and will have impacts on the design of new treatment strategies to combat microbial infections.

## **EXPRESSION ANALYSIS OF LACCASE MULTIGENE FAMILY IN TRAMETES HIRSUTA**

*D. Vasina*<sup>1</sup>, *K. Moiseenko*<sup>1</sup>, *O. Mosunova*<sup>1</sup>, *T. Tyazhelova*<sup>1</sup>, *O. Koroleva*<sup>1</sup>

<sup>1</sup>*Laboratory of Molecular Aspects of Biotransformation,  
A.N.Bach Institute of Biochemistry RAS, Moscow, Russia*

### **Background**

Fungal Laccases (EC 1.10.3.2) are intensively studied due to their wide biotechnological application. However, the laccases industrial use is still limited in knowledge of enzymes biogenesis and its regulation. The regulation of laccase biosynthesis at the transcriptional level is suggested to occur via large number of specific responsive elements in the promoter regions of genes.

### **Objectives**

The work is aimed to study the regulation of multigene laccase family expression in Basidiomycete *Trametes hirsuta* – an effective lignin degrader.

### **Methods**

The full-length cDNA sequences for 7 laccases from *T.hirsuta*, using NGS techniques and RACE-PCR has been obtained. Analysis of laccases promoter regions (with MatInspector software) revealed different composition of cis-elements, including MRE, ACE, XRE, creA etc. Transcriptional dynamics for individual laccase genes were studied under application of different effectors (e.g. copper ions, different groups of xenobiotics) and confirmed with secretome analysis. The laccase complex activity was monitored during the cultivation under all conditions studied.

### **Conclusions**

The major isozyme LacA was found to be expressed in all investigated media, and apparently represented a constitutive laccase form. The expression profiles of six other laccase isozymes and laccase complex activity were different and changed depending on effectors used as well as growth phase. Analysis of transcriptional patterns and modeling of the amino acid structures of laccase isozymes allow suggesting physiological roles and functions of individual laccases, as well as biogenesis regulation within this family.

**INTERACTION OF BOVINE HERPESVIRUS (BHV-1) AND BACILLUS SPP.**

P. Krasochka<sup>1</sup>, D. Borisovets<sup>2</sup>, E. Zhuravleva<sup>3</sup>

<sup>1</sup>*Microbiology and virology, Vitebsk State Academy of Veterinary Medicine, Vitebsk, Belarus*

<sup>2</sup>*Swine viral diseases,*

*Institute of Experimental Veterinary Named By S.N. Vyshelesski, Minsk, Belarus*

<sup>3</sup>*Viral diseases, Institute of Experimental Veterinary Named By S.N. Vyshelesski, Minsk, Belarus*

**Background**

It is well known that some viruses can integrate to genome of eukaryotes. As for prokaryotes there is a special group of viruses – bacteriophages, that can interact with them. But there are almost no information about interaction of viruses pathogenic for animals and bacteria.

The aim of this work is to study possibility of integration of BHV-1 genome and bacillus.

**Methods**

Strains of bacillus were extracted from feces of cattle by standard microbiological procedure.

Screening for antigens of BHV-1 in bacilli was performed by reaction of agglutination (RA test) of bacteria with positive BHV-1 serum.

Screening for genome was done by routine and real-time PCR.

Test for induction of immunity was made by immunizing experimental group of mice with isolates of bacilli twice in 7 days interval. Control group 1 was immunized with vaccine strain of BHV-1, Control group 2 – with sterile saline. Specific antibodies were indicated in reaction of neutralization on MDBK cell culture.

For identification of bacilli automatic biotyper “Vitek” was used.

**Results**

From 70 isolates of bacilli 20 showed positive RA test. And 3 out of this 20 were positive in PCR for glycoproteins D and B genes of BHV-1.

Serums of experimental group of mice were positive for BHV-1 antibodies in dilution up to 1:40, control group 1 - up to 1:60, control group 2 - no antibodies.

Positive bacilli stains were identified as *Bacillus licheniformis*.

**Conclusions**

Obtained results show possibility of interaction and realization of genome of pathogenic viruses in bacteria in natural conditions. Also, application of this bacteria may be possible for diagnostic or prophylactic range.

**CONSORTIUM OF ENZYME-PRODUCING ACTINOMYCETES FROM FRUIT ORCHARD OF MUZAFFARPUR: MOLECULAR IDENTIFICATION BY 16S rRNA GENE SEQUENCE**

S. Kumar<sup>1</sup>, U. Sharma<sup>1</sup>, S. Kumari<sup>1</sup>, R. Krishna<sup>1</sup>, K. Sinha<sup>1</sup>

<sup>1</sup>Botany, B R A Bihar University, Muzaffarpur, India

**Background**

Sucrose gradient method and International Streptomyces Project (ISP) media were adopted to isolate actinomycetes in order to constitute a consortium of actinomycetes from the fruit orchard of Muzaffarpur, which were capable to produce important industrial enzymes. Microscopic, cultural and biochemical tests, followed by features-comparison as per the Bergey's Manual of Systematic Bacteriology confirmed a total of 52 strains in placing their systematic affiliation in the present investigation. The 16S rRNA gene sequencing method confirmed these species belonging to *Streptomyces*, *Nocardia*, *Nocardiopsis* and *Actinomyces*. Based on the consensus nucleotide sequences of ten strains, SK 701 to SK 710, phylogenetic dendrograms were constructed by using neighbour-joining algorithm. Two of these strains, SK 702 and SK 705 were successfully screened to have high phytase activities (380 and 315U ml<sup>-1</sup>, respectively). The optimum extracellular enzyme production was noticed at 35 °C on 4<sup>th</sup> day of culture, when the bacterium entered into late exponential or stationary phase. Though the initial pH of media was 7, however, the phytase production was stable within 3.5 to 4.5 pH.

**Objectives**

The objective is to identify the actinomycetes from fruit orchard because of their capability to produce industrial enzymes and other beneficial compounds at optimum conditions.

**Methods**

ISP and PSM were used to screen phytate-degrading actinomycetes, which were were finally phylogenetically identified by 16S rRNA gene sequencing.

**Conclusions**

Species of *Streptomyces* and *Nocardiopsis* with phytase producing ability were identified in Litchi orchard of Muzaffarpur for which PCR amplification of 643 base pairs of DNA was achieved.

**PHYLOGENETIC HETEROGENEITY OF TUMORIGENIC BACTERIAL STRAINS  
RECOVERED FROM RASPBERRY IN SERBIA**

N. Kuzmanović<sup>1</sup>, A. Prokić<sup>1</sup>, M. Ivanović<sup>1</sup>, N. Zlatković<sup>1</sup>, K. Gašić<sup>2</sup>, A. Obradović<sup>1</sup>

<sup>1</sup>Department of Plant Pathology, University of Belgrade - Faculty of Agriculture,  
Belgrade, Serbia

<sup>2</sup>Department of Plant Pathology, Institute for Plant Protection and Environment,  
Belgrade, Serbia

**Background**

Tumorigenic bacteria belonging to the genera *Agrobacterium* and *Rhizobium* are responsible for crown gall disease of various fruit species. During the last few years, high incidence of crown gall has been recorded in some young raspberry plantations throughout Serbia, causing considerable economic losses.

**Objectives**

The objective was to study phylogenetic structure and diversity of tumorigenic strains occurring on raspberry in Serbia.

**Methods**

A total of 14 strains were isolated from tumor tissue of diseased plants collected in six localities during 2011-2013. Tumorigenicity of strains was determined by PCR using primers specific for tumor-inducing (Ti) plasmid genes and pathogenicity assay on several test plants. PCR targeting the 23S rRNA gene, and 16S rRNA and *recA* gene sequence analysis were used to identify phylogenetic placement of strains studied. Genetic diversity of isolated strains was evaluated by using ERIC-PCR method.

**Conclusions**

Tumorigenic bacteria associated with crown gall of raspberry showed extensive genetic diversity. Out of 14 strains, 12 were identified as tumorigenic *Rhizobium rhizogenes*, one belonged to *Agrobacterium tumefaciens* genomic species G8, while the remaining strain formed separate phylogenetic lineage within *A. tumefaciens* species complex, different from all known genomic species. The fact that some geographically separated *R. rhizogenes* strains exhibited similar ERIC-PCR profiles, may indicate that they have a common origin and were probably disseminated by movement of infected plant material. This study was funded by the national III46008 and EU AREA No 316004 projects.

**UNDERSTANDING THE ROLE OF PII PROTEIN IN ARTHROSPIRA PLATENSIS  
PCC 7345**

S. Lochab<sup>1</sup>, S. Mishra<sup>1</sup>, N. Singh<sup>1</sup>, S. Angmo<sup>1</sup>, N. Raghuram<sup>1</sup>

<sup>1</sup>University School of Biotechnology, GGS Indraprastha University, Delhi, India

**Background**

PII proteins are known to play a crucial role in the regulation of cyanobacterial N metabolism, but its role and interacting partners in *Arthrospira (Spirulina) platensis*, a popular nutraceutical, nitrate-utilizing cyanobacterium, have not been characterized.

**Objectives**

The main aim of this study was to study the regulation of *glnB* (PII) gene by nitrate and its downstream metabolites and to screen for PII interacting proteins in *A. platensis*

**Methods**

We have cloned full length gene (*glnB*) in pET28a vector, expressed and purified PII protein by affinity chromatography for *in vitro* interaction studies. *A. platensis* cDNA yeast two hybrid library was constructed to screen for interacting partners of the PII.

**Conclusions**

Our studies have revealed transcriptional regulation of *glnB* (PII) by nitrate and its downstream metabolites. We have identified 28 colonies after library screening as potential interacting partners. Their characterization and confirmation by other approaches is underway.

<sup>3</sup>Microbiology and Hospital Hygiene, Universitair Ziekenhuis VUB, BRUSSELS, Belgium

<sup>4</sup>Microbiology, Association Régionale de Santé et d'Identification Animale, CINEY, Belgium

<sup>5</sup>Food Science Microbiology, FARAH and Faculty of Veterinary Medicine, LIEGE-SART TILMAN, Belgium

**Background**

In developed countries, *Escherichia coli* producing Shiga toxins (STEC) cause enteritis and (bloody) diarrhoea in young calves and in humans, the haemolytic–uremic syndrome (HUS) in humans, and are also present in the intestines of healthy cattle. Besides the most frequent serotypes, STEC can belong to several subdominant serotypes, like O5:H– that is present in young calves and, though more rarely, in humans and healthy cattle.

**Objectives**

The aim of this study is to analyse, at genome level, the phylogeny of 12 calf (isolated at FVM-ULg and ARSIA) and 4 human (isolated at UZ-VUB) O5 STEC belonging to different pathotypes; the *eae+stx1+* (14 isolates), *eae+stx1+stx2+* (1 isolate) or *stx1+* (1 isolate) pathotypes.

**Methods**

Genomic DNA was extracted from a growing colony and sequenced on the Illumina MiSeq platform. The raw sequences were assembled into scaffolds using an in-house pipeline and subjected to an automated annotation pipeline. The contig data were used to determine the MLST and the pathotypes. A scheme of 20 housekeeping and virulence genes were concatenated and used to select the representative strain, which will be submitted to another run of sequencing and used as the reference for a phylogenomic analysis. The phylogenomic tree will allow to analysing whether the O5 STEC strains could be clustered according to the origin parameter (human or bovine).

## **Conclusions**

Genomic sequencing has become a quick and efficient tool that can be used to replace numerous existing typing analysis methods by a unique analysis scheme.

<sup>2</sup>Environmental Protection, Estacion Experimental del Zaidin (CSIC), Granada, Spain

### Background

Transduction is one of the main drivers of horizontal gene transfer in bacteria and contributes to the rapid evolution of prokaryotes. No transducing phages have yet been described for *Serratia plymuthica*, a biocontrol bacterium that produces bioactive molecules - including the antifungal macrolides, oocydins (1).

### Objectives

The aim of this work was to isolate a generalized transducing phage(s) for *Serratia plymuthica*, and related strains.

### Methods

New phages were isolated, scored for transduction capacity, phenotypically and

morphologically characterised, and genomically sequenced.

## **Conclusions**

The new *Serratia* phage,  $\phi$ MAM1 (2,3), transduced chromosomal markers at high frequencies. We demonstrated transduction of the 77-kbp oocycin gene cluster and showed heterogenic transduction of plasmids. Morphological, genomic and phylogenetic analyses grouped  $\phi$ MAM1 within the suggested new genus, Viunalikevirus (3). We show that four additional viunalikeviruses, infecting plant and human pathogens, were highly efficient generalized transducing phages. We hypothesised that related phages are likely to perform efficient horizontal gene transfer. To test this hypothesis, we first isolated several new viunalikeviruses from the environment,  $\phi$ XF1,  $\phi$ XF3 and  $\phi$ XF4. All these phages transduced chromosomal markers and plasmids at high frequencies (4). We predict that all viunalikeviruses will perform efficient horizontal gene transfer in their respective hosts. These phages will have utility for functional genomics, bacterial engineering and synthetic biology studies, but may be inappropriate candidates for use in phage therapy.

#### **THE COMPLETE GENOME OF MYCOPLASMA SYNOVIAE WVU1853**

M. May<sup>1</sup>, G. Kutish<sup>2</sup>, E.R. Tulman<sup>2</sup>, D. Michaels<sup>3</sup>, A. Barbet<sup>3</sup>, D.R. Brown<sup>3</sup>

<sup>1</sup>Biomedical Sciences, University of New England, Biddeford, USA

<sup>2</sup>Pathobiology and Veterinary Sciences, University of Connecticut, Storrs, USA

<sup>3</sup>Infectious Diseases and Pathology, University of Florida, Gainesville, USA

#### **Background**

*Mycoplasma synoviae* causes infectious synovitis, respiratory tract infections, and eggshell apex abnormalities in commercial poultry. Sequencing of the field isolate MS53 has provided a basis research exploring the virulence and evolution of this organism; however, this isolate is attenuated and is not available to laboratories worldwide. Explorations into loci of interest reveal high levels of genetic diversity between MS53 and other isolates, emphasizing the need to solve the genomes of additional strains. Past efforts have been complicated by a large repeat-rich region encoding variable surface antigens (the *vlhA* locus).

#### **Objectives**

The objective of the work was to generate a complete genome sequence for the *M. synoviae* type strain WVU1853<sup>T</sup> and compare its features to MS53.

#### **Methods**

Sequence reads were generated using a combination of Illumina MiSeq and Pacific Biosciences SMRT technologies. Genome assembly was carried out using CABOG (J. Craig Venter Institute), Newbler (454 Life Sciences), and Ray (Boisvert *et al.*, 2012) assembly software programs.

#### **Conclusions**

The *M. synoviae* WVU1853<sup>T</sup> genome was sequenced and closed. It is larger than the MS53 genome, and many notable changes in the *vlhA* locus were apparent.

## **NIC-GENE CLUSTER'S MODULAR DESIGN WITHIN THE ARTHROBACTER GENUS**

A. Andrei<sup>1</sup>, M. Mihasan<sup>1</sup>

<sup>1</sup>Biology, Alexandru Ioan Cuza University Iasi, Iasi, Romania

### **Background**

The pAO1 megaplasmid of *Arthrobacter nicotinovor*as shows low levels of sequence similarity with ther *Arthrobacter* plasmids, but shares most of its *nic*-genes with three *Arthrobacter* draft genomes: M2012083 (GI:NZ\_AKKK000000000), SJCon (GI:NZ\_AOFD000000000) and AK-YN10 (GI: NZ\_AVPD000000000).

### **Objectives**

The **objective** of the current study is to make an evolutionary analysis of the *nic*-cluster tacking into account the arrangement and collinearity of the *nic* ORF's.

### **Methods**

The three draft genomes of the above mentioned *Arthrobacter* strains were assembled based on on the existing final *Arthrobacter* genomes using MAUVE, annotated with RAST and further aligned with Artemis. *Arthrobacter* sp. AK-YN10 (a gift from Dr. Atya Kapley, CSIR-NEERI, Nagpur, India) and pAO1 strains were grown on citrate medium supplemented with nicotine. Nicotine consumption in the medium was followed by HPLC.

### **Conclusions**

The *nic*-gene cluster can be divided into five modules, each module encoding a precise step in the nicotine-pathway. For each module, a general rule can be observed: the pAO1 modules are the most complex, with a large number of genes, including transposases and insertion elements. The SJCon modules are the most simple, with a small number of ORF's and large non-coding regions. The AK-YN10 strain is somewhere in the middle, but the five modules are spread through the genome. The test for the nicotine resistance of this bacteria has shown levels comparable with the pAO1 strain. Moreover AK-YN10 can grow on nicotine containing citrate media without forming the characteristic nicotine-blue pigment.

**INSIGHTS FROM THE GENOME ANNOTATION OF THE CHROMIUM RESISTANT AND PLANT-GROWTH PROMOTING RHIZOBACTERIUM DELFTIA SP. JD2**

M.A. Morel Revetria<sup>1</sup>, A. Iriarte<sup>2</sup>, E. Jara<sup>3</sup>, H. Musto<sup>3</sup>, S. Castro-Sowinski<sup>4</sup>

<sup>1</sup>*Microbiología Molecular, Instituto de Investigaciones Biológicas Clemente Estable, Montevideo, Uruguay*

<sup>2</sup>*Bioquímica y Genómica Microbiana, Instituto de Investigaciones Biológicas Clemente Estable, Montevideo, Uruguay*

<sup>3</sup>*Organización y Evolución del Genoma, Facultad de Ciencias UdelaR, Montevideo, Uruguay*

<sup>4</sup>*Bioquímica y Biología Molecular, Facultad de Ciencias UdelaR, Montevideo, Uruguay*

**Background**

*Delftia* sp. JD2 is an auxin/siderophore plant-growth-promoting bacterium that promotes growth and nodulation of alfalfa when co-inoculated with *Sinorhizobium meliloti*. Additionally, JD2 reduces Cr(VI) to Cr(III) and shows multi-resistance to several heavy-metals and antibiotics.

**Objectives**

The aims of this work were: 1) to perform a comparative genomic analysis using the draft genome of JD2 and, 2) to analyze the molecular elements involved in JD2 phenotype, such as chromium resistance, auxin- and siderophore-production, among others.

**Methods**

We had recently sequenced the genome of JD2 and its automated annotation has been finished. We are currently analyzing the potential pathways involved in chromate resistance, auxin production, polyhydroxy-alkanoates production and accumulation, horizontal gene transfer elements and others. Results from comparative genomic analysis and different approaches to inferring phylogeny will be shown during the meeting.

**Conclusions**

JD2 has a 6.76Mb genome. The annotation and comparative genomic analysis revealed some functional characteristic associated with its previously reported plant growth promoting effects on alfalfa. JD2 has numerous genes related to tryptophan synthesis and degradation, indol 3-acetic acid biosynthesis, siderophores production and secretion and TonB dependent transporters with various substrate specificities. Consistent with its environmental adaptability, JD2 contains a large number of genes involved in the transport and efflux of toxic compounds. Syntenic genes related to

chromate resistance (*chr*) were identified. Interestingly, in adjacent positions to *chr* cluster some mobile elements (transposases and integrases) were found. The results provide insights into the potential use of JD2 in heavy metal bio-remediation programs and biofertilization technologies.

**SPECIES REASSIGNMENT OF ENTEROBACTER CLOACAE COMPLEX  
ISOLATES BY IN SILICO PHYLOGENETIC ANALYSIS**

L.N. Andrade<sup>1</sup>, A. Novais<sup>2</sup>, R. Branquinho<sup>2</sup>, L. Peixe<sup>2</sup>

<sup>1</sup>*Análises Clínicas Toxicológicas e Bromatológicas (DACTB),  
Faculdade de Ciências Farmacêuticas de Ribeirão Preto (FCFRP) - Universidade de  
São Paulo (USP), Ribeirão Preto, Brazil*

<sup>2</sup>*Ciências Biológicas - Laboratório de Microbiologia,  
UCIBIO/REQUIMTE - Faculdade de Farmácia Universidade do Porto, Porto,  
Portugal*

**Background**

The taxonomic resolution of closely related species belonging to *Enterobacter cloacae* complex ("EcC", *E. cloacae*, *E. hormaechei*, *E. asburiae*, *E. kobei* and *E. ludwigii*) by conventional methodologies or MALDI-TOF MS is often unreliable, and sequencing of 341bp *hsp60* has been proposed for their discrimination. Moreover, a multilocus sequence typing (MLST) assay targeting *dnaA*, *fusA*, *gyrB*, *leuS*, *pyrG*, *rplB* and *rpoB* genes has been suggested for epidemiological typing of *E. cloacae*, considered one of the most frequent species in the clinical setting.

**Objectives**

To assess by a phylogenetic approach, using different biomarkers, the distribution of EcC species in available databases.

**Methods**

A phylogenetic-based study was conducted to analyze the *hsp60* (complete gene) and individual and concatenated sequences of *dnaA*, *leuS* and *rpoB* (partial genes) from 352 *Enterobacter* sp. isolates (including type and/or reference EcC strains), deposited in the Pathosystems Resource Integration Center (Patric) and MLST databases. Phylogenetic trees were constructed using Neighbour-Joining method supported by Tamura 3-parameter model and the reliability of internal branches assessed by bootstrap from 1000 re-samplings.

**Conclusions**

The topology of the trees (individual and concatenated) congruently revealed 5 main clusters corresponding to the five known EcC species. Interestingly, *E. cloacae* were minority (3%), whereas *E. hormaechei* (63%) and *E. asburiae* (15%) were overrepresented, highlighting the current misidentification of EcC species, with potential relevant clinical implications. Finally, cut-off values of  $\leq 91.7\%$  and  $\leq 95.9\%$  are proposed, respectively, for *leuS* and *hsp60*, the most discriminatory genes for EcC species determination, which could support their reliable identification.

**GENETIC ANALYSIS OF THE LISTERIA PATHOGENICITY ISLAND 1 OF *L. MONOCYTOGENES* 1/2A AND 4B ISOLATES**

A. Hadjilouka<sup>1</sup>, S. Paramithiotis<sup>1</sup>, E.H. Drosinos<sup>1</sup>

<sup>1</sup>Food Science and Human Nutrition, Agricultural University of Athens, ATHENS, Greece

**Background**

Genetic analysis of the *Listeria* Pathogenicity Island 1 (LIPI-1) as well as several other genes has been applied in order to gain insights into the evolution of *L. monocytogenes*.

**Objectives**

The aim of the present study was to apply descriptive, phylogenetic, recombination and selection analyses on alignments of the LIPI-1 of 1/2a and 4b isolates of different origin in order to facilitate understanding of the evolution of this virulence gene cluster.

**Methods**

A total of 19 *L. monocytogenes* isolates (9 meat isolates, serotype 1/2a; 5 meat isolates, serotype 4b; 5 strawberry isolates, serotype 4b) were subjected to sequencing of their LIPI-1. Alignments of the complete island as well as intra- and intergenic regions were used for descriptive, phylogenetic, recombination and selection analyses.

**Conclusions**

Descriptive analysis revealed extensive nucleotide diversity mostly in the intragenic regions. The *actA* gene of 1/2a and 4b meat isolates and the *hly* gene of the 4b strawberry isolates exhibited the higher diversity. On the contrary, limited diversity was observed in *prfA* and *plcA* genes of the 4b isolates and *mpl* gene of the 1/2a isolates. Phylogenetic analysis of the complete island resulted in two major clusters that were consistent with serotype assignment of the isolates. Moreover, within the 4b cluster, isolates were separated according to their isolation source. Selection analysis revealed that the island consisted of randomly evolving DNA with the exception of *prfA* gene of 1/2a isolates and *actA* gene of 4b meat isolates for which purifying selection was indicated. Finally, no statistically significant evidence for recombination has been observed.

## **EFFECT OF LEMONGRASS ESSENTIAL OIL ON LISTERIA MONOCYTOGENES GENE EXPRESSION**

A. Hadjilouka<sup>1</sup>, G. Mavrogiannis<sup>1</sup>, S. Paramithiotis<sup>1</sup>, M. Mataragas<sup>1</sup>, E.H. Drosinos<sup>1</sup>

<sup>1</sup>Food Science and Human Nutrition, Agricultural University of Athens, ATHENS, Greece

### **Background**

The transcriptomic response of *L. monocytogenes* to abiotic stresses has been the epicenter of intensive study over the last decade and the complexity of regulation of gene expression has been highlighted.

### **Objectives**

The aim of the present study was to assess the transcriptomic response of *L. monocytogenes* isolates on the exposure to lemongrass essential oil.

### **Methods**

Overnight culture of six strains previously isolated from a strawberry sample was spread over the surface of BHI agar and exposed to 5 and 10 uL of lemongrass essential oil that were applied on a Whatman paper placed on the lid. Three of them survived in the former case and one in the latter; in all cases biomass was collected and RNA was isolated. The expression of the key virulence genes *sigB*, *plcA*, *plcB*, *hlyA*, *inlA*, *inlB*, *inlC*, *inlJ*, *lmo2470* and *lmo2672*, as well as *accA*, *acpP* and *fapR* involved in fatty acid biosynthesis/metabolism and *murE* and *pbpB* involved in peptidoglycan biosynthesis was assessed by RT-qPCR.

### **Conclusions**

Downregulation of virulence genes was observed with the exception of *sigB* for which upregulation in two isolates was observed. On the contrary, significant differences between the isolates were observed regarding the expression of *accA*, *acpP*, *fapR*, *murE* and *pbpB*. The increased amount of lemongrass essential oil affected significantly the expression of *accA*, *pbpB*, *sigB*, *hlyA*, *inlA*, *inlB*, *inlJ* and *lmo2672*.

**AN HOMOLOG OF THE FRZ PHOSPHOENOLPYRUVATE: CARBOHYDRATE PHOSPHOTRANSFERASE SYSTEM OF EXTRAINTESTINAL PATHOGENIC ESCHERICHIA COLI IS ENCODED ON A GENOMIC ISLAND IN SPECIFIC LINEAGES OF STREPTOCOCCUS AGALACTIAE**

K. Patron<sup>1</sup>, P. Gilot<sup>1</sup>, E. Camiade<sup>1</sup>, L. Mereghetti<sup>1</sup>

<sup>1</sup>Bactéries et Risque Maternofoetal, UMR 1282 (Université de Tours/Inra) - ISP, Tours, France

**Background**

*Streptococcus agalactiae* and *Escherichia coli* have in common the capability to colonize and infect similar hosts, and to survive in the environment and in foods. In *E. coli*, the Frz system is involved in environmental sensing and regulation of the expression of adaptation and virulence genes. Thus, it is possible that *S. agalactiae* possesses a system similar to Frz to sense its environment and to adapt to environmental conditions.

**Objectives**

The presence of a system similar to Frz was searched in *S. agalactiae* strains representative of the genetic diversity of the species.

**Methods**

The genomes of 492 strains of *S. agalactiae* of human and animal origins were analyzed *in silico* and by PCR. The strains were characterized by multilocus sequence typing.

**Conclusions**

We identified an operon (named *fru<sub>2</sub>*) coding a system similar to Frz. *fru<sub>2</sub>* encodes three subunits of a PTS transporter of the fructose-mannitol family, a transcriptional activator of PTSs of the MtlR family, an allulose-6 phosphate-3-epimerase, a transaldolase and a transketolase. *fru<sub>2</sub>* is present in a genomic island. The showed that the presence of *fru<sub>2</sub>* is closely linked to the phylogeny of *S. agalactiae*. Our results indicate that *fru<sub>2</sub>* was acquired during the evolution of *S. agalactiae* before the divergence of CCs 1, 7, 10 and 283, and STs 130 and 288. As *S. agalactiae* strains of CCs 1 and 10 are frequently isolated from adults with invasive disease, we hypothesize that the *S. agalactiae fru<sub>2</sub>* system senses the environment to allow the bacterium to adapt to new conditions encountered during the infection of adults.

## **COEVOLUTION OF HUMAN AND HELICOBACTER PYLORI GENOMES SHAPES THE RISK OF GASTRIC DISEASE**

A. Pazos<sup>1</sup>, N. Kodaman<sup>2</sup>, B.G. Schneider<sup>3</sup>, M.B. Piazuelo<sup>3</sup>, C.L. Shaffer<sup>3</sup>, L.E. Bravo<sup>4</sup>, R.M. Peek<sup>3</sup>, K.T. Wilson<sup>3</sup>, T.L. Cover<sup>3</sup>, S.M. Williams<sup>3</sup>, P. Correa<sup>3</sup>

<sup>1</sup>Department of Biology, University of Nariño, Pasto, Colombia

<sup>2</sup>Department of Molecular Physiology and Biophysics, Vanderbilt University, Nashville TN, USA

<sup>3</sup>Division of Gastroenterology Department of Medicine, Vanderbilt University, Nashville TN, USA

<sup>4</sup>Department of Pathology, University of Valle, Cali, Colombia

### **Background**

*Helicobacter pylori* is the principal cause of gastric cancer (GC). However, *H. pylori* prevalence generally does not predict cancer incidence

### **Objectives**

To determine if the coevolution between host and pathogen influences the risk of GC in two Colombian populations: Tumaco, a coastal population with low risk of GC, and Tuquerres, a mountain population with high risk of GC. Our hypothesis postulates an association between the severity of gastric lesions and the patterns of genomic variation in matched human and *H. pylori* samples

### **Methods**

292 patients were recruited from the two populations. Histological diagnostics were based on the Sydney classification. 252 strains of *H. pylori* were included for MLST analysis. Human DNA was genotyped using the ImmunoChip to characterize the human ancestry. The Admixture model of STRUCTURE assigns proportions of ancestry to each individual sample

### **Conclusions**

*H. pylori* isolates with an ancestral African cluster predominating in a low-risk (coastal population), and a European cluster in a high-risk (mountain population). The human ancestries of biopsied individuals also vary geographically, with mostly African ancestry in the coastal region, and mostly Amerindian ancestry in the mountain region. The interaction between host and pathogen ancestries completely accounted for the difference in the severity of gastric lesions in the two regions of Colombia. *H. pylori* ancestry was relatively benign in humans of African ancestry but was deleterious in individuals with Amerindian ancestry. Thus, coevolution probably shapes disease risk, and the disruption of coevolved human and *H. pylori* genomes can explain the high incidence of gastric disease in mountain population.

**EXPLORING GENETIC DIVERSITY OF XANTHOMONAS ARBORICOLA PV. CORYLINA STRAINS AND DEVELOPMENT OF SPECIFIC MOLECULAR MARKERS**

A. Prokic<sup>1</sup>, M. Ivanovic<sup>1</sup>, N. Kuzmanovic<sup>1</sup>, K. Gasic<sup>2</sup>, N. Zlatkovic<sup>1</sup>, A. Obradovic<sup>1</sup>

<sup>1</sup>Phytopathology, University of Belgrade Faculty of Agriculture, Belgrade, Serbia

<sup>2</sup>Phytopathology, Institute for plant protection and environment, Belgrade, Serbia

Background: *Xanthomonas arboricola* pv. *corylina* (Xac) is the causal agent of bacterial blight of hazelnut. The most efficient distribution of the pathogen to new geographical areas occurs through contaminated plant material. Therefore, fast and reliable pathogen detection using highly specific molecular diagnostic tools is essential for the production of disease-free planting material.

Objectives: The aim of this work was to study genetic structure and diversity of Xac strains and develop molecular tools for specific and rapid detection of the pathogen.

Methods: In order to study genetic diversity forty Xac strains originating from Serbia were initially analyzed by rep-PCR using BOX, ERIC and REP primers. Obtained genetic profiles from all three PCR methods were transformed into a binary matrix, combined and used for phylogenetic analysis and construction of the dendrogram. Seventeen representative strains with different rep-PCR patterns were selected for further macrorestriction analysis using *SpeI* restriction enzyme and pulsed-field gel electrophoresis (PFGE). Specific primers were designed based on specific DNA fragment obtained by ERIC-PCR.

Conclusions: The strains were differentiated into eight clonal and highly related genetic groups by rep-PCR analysis. Unique PFGE patterns were obtained for each representative strain indicating more polymorphism between the strains, compared to rep-PCR. Designed PCR set of primers enabled detection of Xac strains from different geographic origin. However, they could not distinguish Xac from closely related *Xanthomonas* spp.

## **EXPLORING DIVERSITY AND EVOLUTION OF MICROBIAL GENOMES USING NEXT-GENERATION SEQUENCING**

T. Roychowdhury<sup>1</sup>, A. Bhattacharya<sup>2</sup>

<sup>1</sup>*School of Computational & Integrative Sciences,  
JAWAHARLAL NEHRU UNIVERSITY, NEW DELHI, India*

<sup>2</sup>*School of Life Sciences, JAWAHARLAL NEHRU UNIVERSITY, NEW DELHI, India*

### **Background**

Genome organization and sequence is dynamic, undergoing changes as part of evolutionary process based on genomic structure and environmental conditions under which organisms grow. The whole genome sequences (WGS) are useful information to understand evolutionary aspects of any organism. We have used Next-generation sequencing (NGS) to survey and analyse genomic changes occurring in different species and isolates of bacteria..

### **Objectives**

1. Identification and analysis of mutation hotspots in genome of *M.tuberculosis*.
2. Construction of phylogenetic trees from NGS datasets of microbes.
3. Identification of IS-elements from NGS datasets and understanding role of IS6110 in genome evolution of *M.tuberculosis*.

### **Methods**

1. We have used Shewhart Control Chart to identify genomic mutation hotspots in *M.tuberculosis*.
2. We have developed a method which uses random sampling of genome to reduce computational complexity to construct phylogenetic tree. It is able to construct trees in absence of reference genome, which is important for non-model organisms. This was used for NGS datasets of *M.tuberculosis*, *E.coli* and *V.cholerae*.
3. We have used a split-read approach to identify location of IS elements in microbial genome from NGS datasets. Distribution and copy number of IS6110 was identified from 1377 *M.tuberculosis* strains representing all major global lineages.

### **Conclusions**

Identification and analysis of hotspots enables to study regions responsible for diversification and phenotypic consequences such as, drug-resistance. Generation of phylogenetic trees directly from NGS reads enables study of evolutionary relationships among hundreds of closely related strains. Lineage specific IS6110 distributions were observed and gene truncation, possible promoter activity and IS mediated genomic rearrangements were studied in detail.

## **A POSSIBLE EVOLUTIONARY SCENARIO FOR THE LOSS OF OPGGH IN YERSINIA PESTIS.**

K. Quintard<sup>1</sup>, A. Reboul<sup>1</sup>, E. Madec<sup>2</sup>, A. Dewitte<sup>1</sup>, J. Dondeyne<sup>2</sup>, M. Marceau<sup>1</sup>, M. Simonet<sup>1</sup>, E. Pradel<sup>1</sup>, J.M. Lacroix<sup>2</sup>, F. Sebbane<sup>1</sup>

<sup>1</sup>Plague and *Yersinia pestis* group, Inserm U1019 - Institut Pasteur de Lille, LILLE, France

<sup>2</sup>Unité de Glycobiologie Structurale et Fonctionnelle, Lille - Nord de France University, LILLE, France

### **Background**

The *opgGH* operon encodes the glycosyltransferases OpgH and OpgG, which synthesize osmoregulated periplasmic glucans (OPGs) and are required for motility, biofilm formation and virulence in various bacteria. OpgH also sequesters FtsZ, in order to control bacterial size as a function of nutrient availability. The role of *opgGH* in *Yersinia pseudotuberculosis* is unknown. Furthermore, *opgGH* was lost during the emergence of *Yersinia pestis* (the agent of plague) from *Y. pseudotuberculosis* (an enteropathogen). This loss is surprising, since *Y. pestis* is extremely virulent and flea-borne transmission of *Y. pestis* relies on biofilm formation.

### **Objectives**

To determine the role of *opgGH* in *Y. pseudotuberculosis* and consider the role of *opgGH*'s loss in the emergence of plague.

### **Methods**

Genetic approaches were used to generate (i) a  $\Delta$ *opgGH* *Y. pseudotuberculosis* strain, and (ii) *Y. pestis*,  $\Delta$ *opgGH* *Escherichia coli* and  $\Delta$ *opgGH* *Dickeya dadantii* strains expressing *Y. pseudotuberculosis* *opgGH*. Biochemical assays (used to detect OPG synthesis), motility and biofilm assays, microscopy (used to measure bacterial size) and virulence testing (using endive leaves, mice and fleas) were used to determine the impacts of the mutation and the *opgGH* expression in the strains of interest. Animal studies were performed in compliance with the French regulations.

### **Conclusions**

Our results suggest an evolutionary scenario in which an ancestral strain of *Yersinia* lost or did not acquire a cofactor that was important for OPG biosynthesis but kept *opgGH* to control its bacterial size in a nutrient-dependent manner. The *opgGH* gene was then lost presumably because the nutrient-dependent size-control mechanism was no longer necessary.

**PHYLOGENETIC ANALYSIS OF TREPONEMA PALLIDUM SUBSP. PALLIDUM, PERTENUE AND ENDEMICUM STRAINS: IDENTIFICATION OF POSITIVELY SELECTED GENES**

D. Smajs<sup>1</sup>, L. Paštěková<sup>1</sup>, D. Čejková<sup>1</sup>

<sup>1</sup>Department of Biology, Masaryk University Faculty of Medicine, Brno, Czech Republic

**Background**

The genus *Treponema* comprises several uncultivable human pathogens including *Treponema pallidum* subsp. *pallidum* (TPA), the causative agent of syphilis, *T. p.* subsp. *pertenue* (TPE, the causative agent of yaws), and *T. p.* subsp. *endemicum* (TEN, the causative agent of bejel).

**Objectives**

The goal of this study was to identify positively selected genes in comparisons within and between TPA, TPE and TEN strains.

**Methods**

Altogether, nine whole genome sequences comprising 4 TPA, 4 TPE and 1 TEN strains were used to identify positively selected genes. Several software packages were used including Mega4, PAML and TimeZone in all possible pairwise combinations.

**Conclusions**

A set of 25 treponemal genes were identified among more than 1000 tested TPA, TPE and TEN orthologous genes. Eleven of these genes were found to be positively selected in TPA-TPE comparisons but not within TPA or TPE strains. In contrast, five genes including *bamA* and *mcp-2* were positively selected also within TPA and TPE strains. Two genes (TP0559, TP0966) appear to be positively selected within TPA but not within TPE strains suggesting their role in syphilis pathogenesis. Gene TP0304 is positively selected within TPE but not within TPA. Two genes (*tprF*, *I*) were found positively selected within TPA and TPE strains but not in comparison between TPA and TPE strains. Except for *tprC* gene where positive selection was identified between TPA and TPE comparisons, TEN orthologs resembled TPE orthologs. Altogether, positively selected genes encode for Tpr proteins, protein antigens (e.g. TP0326, BamA), putative lipoproteins and outer membrane proteins.

**KEY FEATURES FOR THE ADAPTION AND SURVIVAL OF LISTERIA MONOCYTOGENES IN THE FOOD PROCESSING ENVIRONMENT**

M. Muhterem-Uyar<sup>1</sup>, M. Wagner<sup>1</sup>, S. Schmitz-Esser<sup>1</sup>, B. Stessl<sup>1</sup>

<sup>1</sup>Vetmeduni Vienna, Institute of milk hygiene milk technology and food science, Vienna, Austria

**Background**

The saprophyte *L. monocytogenes* is well established in the environment.

**Objectives**

Persistent *L. monocytogenes* and *Listeria* spp. isolates (characterized by PFGE and MLST typing) are hypothesized to be better adapted to the food processing environment (FPE).

**Methods**

The whole genome of 15 *L. monocytogenes* and *Listeria* spp. genotypes established in the same food processing environment was sequenced applying the Illumina sequencing technique.

**Conclusions**

The *L. monocytogenes* core-genome was highly syntenic. Differences were detected in mobile elements of the accessory genome. Eight *L. monocytogenes* and two *L. innocua* strains indicated the presence of 15-90 kbp plasmids. The long-term *L. monocytogenes* persistent strains, assigned to genetic lineage I [sequence type (ST) 5] and lineage II (ST204), harbored a plasmid comparable to plm80. When comparing *L. monocytogenes* ST37 at the beginning and the end of isolation, the loss of a distinct phage region (~33 kbp) was noticeable. The  $\beta$ -lactamase encoding transposon Tn552, was detected in the plasmids of *L. monocytogenes* ST204 (n=1) and ST5 strains (n=6). The transposon Tn554, suspected for benzalkonium resistance, was found in *L. monocytogenes* ST9, one *L. innocua*, and *L. seeligeri*. The *L. monocytogenes* stress-survival islet (SSI-1) was present in ST5, ST204, and ST9.

The results indicate mutations in the *L. monocytogenes* ST5, ST37 phage and/or plasmid genome suspected for better adaption and survival in the particular FPE. Gene regions for better adaption to disinfectants and acidic stress (Tn554, SSI-1) were found in long term persistent *L. monocytogenes* strains.

**AN IMPROVED CLASSIFICATION OF DYP-TYPE PEROXIDASE FAMILY  
ACCELERATES THE RESEARCH OF THE FAMILY**

Y. Sugano<sup>1</sup>, T. Yoshida<sup>2</sup>

<sup>1</sup>*Chemical and Biological Sciences, Japan Women's University, Tokyo, Japan*

<sup>2</sup>*Faculty of Life Science, Kyoto Sangyo University, Kyoto, Japan*

**Background**

So far, the range of DyP-type peroxidase family was obscure. Therefore, the name of DyP-type peroxidase family and its superfamily tended to be confused.

**Objectives**

To solve this problem, we focus on the relationship between tertiary and primary structures of DyP-type peroxidases associated with their function. From the viewpoint, we propose the range of DyP-type peroxidase family reasonably.

**Methods**

Dye-decolorizing peroxidase from the basidiomycete *Bjerkandera adusta* Dec 1 (DyP) is a heme peroxidase. This name reflects its ability to degrade several anthraquinone dyes. The substrate specificity, the amino acid sequence, and the tertiary structure of DyP are different from those of the other heme peroxidase families. Therefore, many proteins showing the similar amino acid sequences to that of DyP are called DyP-type peroxidase which is a new family of heme peroxidase identified in 2007. Although all structures of this family show a similar structure fold, this family includes many proteins whose amino acid sequence identity to DyP is lower than 15%. Moreover, their catalytic efficiency ( $k_{\text{cat}}/K_{\text{m}}$ ) is a few orders of magnitude less than that of DyP. For the activity, some of them have been reported different from peroxidase activity (dechelataase activity).

**Conclusions**

Here, we report the differences and similarities of structure and function among this family and propose the reasonable improved classification of DyP-type peroxidase family, that is, class P, I and V. This classification is rather sophisticated and accelerates the logical study for DyP-type peroxidase family.

**APPLICATION OF GENOMICS TO PROKARYOTIC SYSTEMATICS: THE GENUS RHODOCOCCLUS AS A CASE STUDY**

V. Sangal<sup>1</sup>, A.J. Jones<sup>1</sup>, M. Goodfellow<sup>2</sup>, P.A. Hoskisson<sup>3</sup>, I.C. Sutcliffe<sup>1</sup>

<sup>1</sup>Applied Sciences, Northumbria University, Newcastle upon Tyne, United Kingdom

<sup>2</sup>School of Biology, Newcastle University, Newcastle upon Tyne, United Kingdom

<sup>3</sup>Strathclyde Institute of Pharmacy and Biomedical Sciences, Strathclyde University, Glasgow, United Kingdom

**Background**

Prokaryotic systematics provides the framework for all research in microbiology. Just as 16S rRNA gene sequence analysis revolutionised prokaryotic systematics a generation ago, genome sequence analyses now have the power to be a similarly disruptive technology. Case studies are needed to highlight the power of the new methodological approaches.

**Objectives**

To apply whole genome sequence analyses to reappraise the taxonomy of genus *Rhodococcus*.

**Methods**

We have determined genome sequences for 15 strains belonging to the genus *Rhodococcus*. Using this data and publicly available sequences, we have analysed genome sequences of 83 strains of 20 species within the genus *Rhodococcus* using phylogenomic, genetic and functional distance-based approaches.

**Conclusions**

Based on our analyses the rhodococci were resolved into six robust lineages that were as distant from each other as they were from other genera including representatives of *Nocardia* and *Gordonia*. These analyses also revealed a widespread problem of strain misidentification using classical approaches. The lineage containing *Rhodococcus rhodochrous*, the type species of the genus, represents the genus *Rhodococcus sensu stricto*. However, the others can potentially be designated as novel genera. *Rhodococcus equi* formed a distinct lineage with *Rhodococcus defluvii* consistent with our recent proposal that the former should be reclassified as "*Prescottella equi*". These data provide a case study demonstrating that genome sequencing is a cost effective and powerful tool for resolving complex taxonomic questions.

#### THE PLASMID COMPLEMENT OF LACTOCOCCUS LACTIS NCDO712

M. Tarazona<sup>1</sup>, R. Siezen<sup>2</sup>, M. Beerthuyzen<sup>3</sup>, A. de Jong<sup>4</sup>, M. Wels<sup>5</sup>, J. Kok<sup>6</sup>,  
H. Bachmann<sup>3</sup>

<sup>1</sup>Health/Molecular Genetics, TIFN/RUG/NIZO Food Research, Ede, Netherlands

<sup>2</sup>Bioinformatics, RadboudUMC/Microbial Bioinformatics, Nijmegen/Ede, Netherlands

<sup>3</sup>Health, TIFN/NIZO Food Research, Ede, Netherlands

<sup>4</sup>Bioinformatics Genomics, TIFN/RUG, Groningen, Netherlands

<sup>5</sup>Bioinformatics and Computational Biology, TIFN/NIZO/RadboudUMC,  
Ede/Nijmegen, Netherlands

<sup>6</sup>Molecular Genetics, TIFN/RUG, Groningen, Netherlands

#### Background

The lactic acid bacterium *Lactococcus lactis* NCDO712 was isolated from a dairy starter culture in the 1950s and it is the ancestor of the prophage and plasmid cured model strain MG1363. *L. lactis* NCDO712 was described to contain 5 plasmids (~50 kb, 13.6 kb, 8 kb, 3.8 kb, 2.7 kb) of which so far only two have been sequenced.

#### Objectives

The characterization of *L. lactis* NCDO172 will help establishing it as a relevant model strain because of its functional proximity to commercially used cultures. In combination with the genetically highly accessible derivative MG1363, it will form a useful couple to study industrially relevant traits of *L. lactis*.

#### Methods

Total DNA of *L. lactis* NCDO712 was sequenced using Illumina and PacBio. Additional PCR reactions and Southern hybridizations were done to complete the assembly. This resulted in 5 circular plasmids and one linear plasmid contig and allowed a SNP comparison with MG1363.

#### Conclusions

We here sequenced the complete plasmid complement of strain NCDO712, which resulted in the identification of 6 plasmids (55.4kb, 8.6kb, 3.6kb, 2.1kb, 15.5kb, 51.7kb) - one more than initially described. Next to an extracellular protease gene and the genes necessary for lactose utilization, which are on the already sequenced plasmid pLP712, the other plasmid-encoded genes include those of a variety of IS-located transposases, two restriction modification systems (specificity subunits) and stress related genes. The sequencing of the total DNA of strain NCDO712 also allowed identifying of some chromosomal differences between the strains NCDO712 and MG1363.

**SEQUENCING AND ANNOTATION OF THE GENOME FROM THE FILAMENTOUS FUNGUS *ACREMONIUM CHRYSOGENUM*, THE PRODUCER OF THE BETA-LACTAM ANTIBIOTIC CEPHALOSPORIN C**

D. Terfehr<sup>1</sup>, T. Dahlmann<sup>1</sup>, T. Specht<sup>2</sup>, I. Zadra<sup>2</sup>, H. Kürnsteiner<sup>2</sup>, U. Kück<sup>1</sup>

<sup>1</sup>Department of General and Molecular Botany, Ruhr-University Bochum, Bochum, Germany

<sup>2</sup>Anti-Infectives Microbiology, Sandoz GmbH, Kundl, Austria

**Background**

*Acremonium chrysogenum* is the industrial fungal producer of the  $\beta$ -lactam antibiotic cephalosporin C, which is an important drug due to its broad activity against Gram-positive and Gram-negative bacteria. The source material for the modern chemically modified cephalosporin C derivatives is still mainly produced by *A. chrysogenum*, which marks its importance for biotechnology and medicine.

**Objectives**

Therefore it is of high interest to gain a deeper insight into the biosynthetic processes involved in cephalosporin C production and their regulation. Already established molecular tools like homologous recombination and the FLP/FRT marker recycling system are essential for the work with this fungus. A further crucial step for effective scientific research with *A. chrysogenum* is to disclose its genomic sequence.

**Methods**

DNA sequencing, sequence assembly, annotation

**Conclusions**

After quality trimming and assembly we were able to obtain a genome sequence with an overall length of 28.6 Mb distributed on 542 scaffolds. Furthermore 8901 protein coding genes were annotated using the protein data from closely related species and the UniProtKB/Swiss-Prot database. The potential to produce a variety of secondary metabolites is underlined by 42 putative secondary metabolite cluster found in the genome sequence. The available genomic sequence and annotation of *A. chrysogenum* represents a versatile platform for future functional genomic approaches (1).

## **IN SILICO STRATEGIES FOR THE IDENTIFICATION AND CLASSIFICATION OF BACTERIAL AUTOTRANSPORTER PROTEINS**

D. Udatha<sup>1</sup>, L. Dirk<sup>1</sup>

<sup>1</sup>*Department of Biosciences, University of Oslo, Oslo, Norway*

### **Background**

Autotransporters are the representatives of the type V secretion system proteins that are assembled into the outer membrane of bacterial cells, and are the most prevalent of the seven types of secretion systems in gram-negative bacteria.

### **Objectives**

The huge data from genome sequencing studies provides a resource of autotransporter proteins as well as pose a challenge in the identification and classification of the autotransporter sequences. We interrogate the bioinformatics strategies to address questions that increase our understanding of sequence-structure-function relationships in autotransporter proteins.

### **Methods**

By using the properties of the whole sequence we propose a new classification system for autotransporter proteins has been proposed. A Support Vector Machine model was subsequently constructed for the identification and classification of new FAEs into the pre-assigned clusters.

### **Conclusions**

This study centers on the descriptor-based classification and structural analysis of experimentally verified and putative autotransporter proteins; nevertheless, the framework presented here is applicable to every poorly characterized enzyme family.

**TEMPERATURE-INDUCED MUTAGENESIS AND MORTALITY IN CUPRIAVIDUS METALLIDURANS STRAINS**

J. Vandecraen<sup>1</sup>, P. Monsieus<sup>1</sup>, N. Leys<sup>1</sup>, M. Mergeay<sup>1</sup>, A. Aertsen<sup>2</sup>, R. Van Houdt<sup>1</sup>

<sup>1</sup>Unit of Microbiology, SCK•CEN, Mol, Belgium

<sup>2</sup>Microbial and Molecular Systems, KU Leuven, Leuven, Belgium

**Background**

*Cupriavidus metallidurans* is a  $\beta$ -proteobacterium which can be found in industrialized and anthropogenic environments. It was previously observed that growth of *C. metallidurans* CH34 at 37°C in rich media leads to high mortality (TIMM).

**Objectives**

The aim of this study is: (i) to scrutinize TIMM-inducing media and (ii) to investigate this phenomenon at the genetic and molecular level.

**Methods**

First, TIMM-induction was analyzed with different growth media. Next, the TIMM-phenotype was studied using a time-lapse microscope. Finally, whole-genome sequence analyses were performed for two derivatives with inherited resistance to all tested TIMM-inducing media.

**Conclusions**

The individual amino acids phenylalanine and cysteine and high ammonium concentrations could activate TIMM at 37°C in *C. metallidurans* CH34. Moreover, a mineral medium with low salt concentrations, i.e. Schatz-medium, also induced a high mortality at 37°C. These observations led to the hypothesis that different TIMM-inducing triggers are responsible for the phenotype. First, uptake of specific amino acids can lead to a toxic imbalance. Second, the TIMM-phenotype could be linked with osmotic potential and membrane integrity as characteristics like cell elongation, reproduction halting and cell lysis were induced. Interestingly, counteractivating agents were found as induction was inhibited by increasing the osmotic potential of Schatz-medium or by adding sorbitol to the different TIMM-inducing media. Both observations provided support for the hypothesis that membrane integrity plays a crucial role in the TIMM-phenotype. A common missense mutation was identified in a gene coding for an alcohol dehydrogenase. To examine the effect of this mutation complementation studies are currently being performed.

**Microbial genomics, evolution, phylogeny**

## **AN UNUSUAL STRAIN WHICH PROBABLY BE AN ANCESTOR IN THE EVOLUTIONARY PROCESS OF YERSINIA**

X. WANG<sup>1</sup>, G. Shi<sup>2</sup>, J. Liang<sup>1</sup>, R. Duan<sup>1</sup>, H. Jing<sup>1</sup>

<sup>1</sup>Laboratory of Yersinia,

National Institute for Communicable Disease Control and Prevention China CDC,  
Beijing, China

<sup>2</sup>Institute for Communicable Disease,

Zhejiang Provincial Centre for Disease Control and Prevention, Hangzhou, China

### **Background**

We had isolated an unusual *Y. enterocolitica* strain from *Rattus norvegicus*, the brown rat. The strain did not utilize urea where API 20E identified *Escherichia coli*; however it grew well at 25°C where *E. coli* does not. We deduced the strain was *Y. enterocolitica* using sequence alignment of the 16 S rRNA gene.

### **Objectives**

To analysis the discrepancy with other *Y. enterocolitica* and comprehend its location in the evolutionary process of *Yersinia* by sequencing the whole genome of LC20.

### **Methods**

The LC20 genome was sequenced using a whole-genome shotgun sequencing strategy and Illumina Hiseq sequencing technology.

### **Conclusions**

Whole-genome comparison confirmed LC20 was *Y. enterocolitica*, the whole genome was collinear with *Y. enterocolitica* 8081. LC20 carried a great number of predicted CDSs and IS elements. Two plasmids shared low genetic homology with pYV from the *Yersinia* genus, one was an ancestral *Yersinia* plasmid and the other was novel encoding a number of transposases. The core-based and pan-based phylogenetic trees showed LC20 was classified into *Y. enterocolitica* cluster but on a distinct branch, which was closer to *Y. pestis* and *Y. pseudotuberculosis*. Some pathogenic and non-pathogenic *Y. enterocolitica* specific genes coexist in LC20. The urease gene did not exist on the genome consistent with API 20.

LC20 is sub-classified into *Y. enterocolitica* based at the level of the whole genome,

though its bacterial identification coding system of biochemical metabolism showed it was *E. coli*. The strain may be a progenitor of *Y. enterocolitica* and represent even an ancestor in the evolutionary process of *Yersinia* genus.

**CHARACTERIZATION OF A NOVEL SULFATE-REDUCING BACTERIUM  
POSSESSING DESULFOVIRIDIN AND VIBROID MORPHOLOGY, BELONGING  
TO THE FAMILY DESULFOMICROBIACEAE**

M. Watanabe<sup>1</sup>, H. Kojima<sup>1</sup>, M. Fukui<sup>1</sup>

<sup>1</sup>The Institute of Low Temperature Science, Hokkaido University, Sapporo, Japan

**Background**

The order *Desulfovibrionales* is organized in four families; *Desulfovibrionaceae*, *Desulfonatronumaceae*, *Desulfohalobiaceae* and *Desulfomicrobiaceae*. The genus *Desulfomicrobium* is a sole member of family *Desulfomicrobiaceae* at the time of writing. The genus have been characterized as rod- or ellipsoidal-shaped morphology and absence of desulfovridin. In this study, a novel strain Pf12B<sup>T</sup> related to *Desulfomicrobium* species was isolated in pure culture.

**Objectives**

The aim of our study is characterization of the strain Pf12B<sup>T</sup>.

**Methods**

Strain Pf12B<sup>T</sup> was obtained from an enrichment culture established under sulfate-reducing conditions at 45°C with an inoculum of sediment from a brackish meromictic lake. Isolation of the strain was carried out by repeated agar shake dilution method.

**Conclusions**

Cells were vibroid, and motile. The closest relative of the strain was *Desulfomicrobium baculatum* with 16S rRNA gene sequence similarity of 91%. Phylogenetic analysis based on the 16S rRNA gene sequence revealed that the strain Pf12B<sup>T</sup> belonged to the family *Desulfomicrobiaceae*, in the order *Desulfovibrionales*, *Deltaproteobacteria*. This result was also supported by the phylogenetic analysis based on DsrA amino acid sequence. Sulfate, sulfite, thiosulfate were used for electron acceptors. Formate and fumarate were used for substrate in the presence of sulfate. Yeast extract enhanced growth of the strain. The isolate grew at temperatures between 13-50°C with an optimum temperature range of 42-45°C. The strain was desulfovridin positive. Major cellular fatty acids of the isolate were C<sub>16:0</sub> and C<sub>18:0</sub>. It was suggested that the strain Pf12B<sup>T</sup> is a representative of novel species of novel genus within the family *Desulfomicrobiaceae*.

**Background**

Dye-decolorizing peroxidase (DyP)-type peroxidase is a new family of heme peroxidase, distributing from bacteria to fungi. This name derives from the degradation ability of anthraquinone dyes. DyP-type peroxidases are known to show the similar structure. On the other hand, this family includes many proteins which show very low amino acid sequence similarity, resulting in inaccurate sequence alignment. This family has been subdivided into four classes (A, B, C, and D) based on the amino acid sequences. Recently, we reassessed the sequence alignment of DyP-type peroxidases using structure-based sequence alignment. The generated alignment reflected the differences hidden in the similar structures. Based on this result, we proposed the new subclass into three classes (P, I, and V). Here, classes P, I and V mean former classes B, A, and C with D, respectively. The structures of proteins of former classes C and D are almost same.

**Objectives**

*Anabaena* sp. DyP-type peroxidase (AnaPX) has been classified into different class (C or D) by different researchers. Therefore, it is expected that structure-based sequence alignment including the structure of AnaPX gives an insight into the subclass, especially, class V.

**Methods**

We determined the structure of AnaPX by X-ray crystallography and generated phylogenetic tree using MATRAS program (T. Kawabata, *Nucleic Acids Res.* **31**, 3367–3369 (2003)) as multiple three-dimensional alignment tool.

**Conclusions**

AnaPX showed the almost same structure as another structures belonging to class V and belonged to class V branch. This result supports our proposition that the border between former classes C and D is vague.

**GENOMIC EPIDEMIOLOGY OF MULTIPLE ACINETOBACTER BAUMANNII OUTBREAKS IN A VETERINARY INTENSIVE CARE UNIT**

A. Zomer<sup>1</sup>, B. Duim<sup>1</sup>, E. Broens<sup>1</sup>, J.W. Rosser<sup>2</sup>, J. Robben<sup>1</sup>, M. Leendertse<sup>3</sup>, J.A. Wagenaar<sup>1</sup>, J. Hordijk<sup>1</sup>

<sup>1</sup>Department of Infectious Diseases and Immunology Faculty of Veterinary Medicine, Utrecht University, Utrecht, Netherlands

<sup>2</sup>Medical Microbiology, University Medical Center Groningen, Groningen, Netherlands

<sup>3</sup>Medical Microbiology, Academic Medical Center Amsterdam, Amsterdam, Netherlands

**Background**

*Acinetobacter baumannii* is an emerging pathogen primarily found in health-care associated settings. Due to its potential to acquire and control antimicrobial resistance and its ability to survive for extended periods in the environment, outbreaks are a threat and challenge for health care. Molecular epidemiology of *A. baumannii* is difficult because typing methods often lack resolution to identify transmission chains. Whole genome sequencing (WGS) forms an alternative method to investigate whether repeated outbreaks are independent events or are linked.

**Objectives**

Investigation into the relatedness of two outbreaks of *A. baumannii* in the companion animal intensive care unit (calCU) at Utrecht University in 2012 and 2014.

**Methods**

Multi Locus Sequence Typing (MLST) was performed for both outbreaks. All outbreak strains, three European Control strains (EC-I, -II and -III) and four environmental strains were sequenced on an Illumina Miseq platform. Genomes were assembled using SPAdes, horizontal gene transfer was detected using ClonalFrame, time-measured phylogeny was reconstructed using BEAST.

**Conclusions**

MLST of the isolates revealed that all animal isolates from both outbreaks in the calCU belong to ST2. Isolates from the outbreaks had similar resistance phenotypes, suggesting that the events are linked. Time-measured phylogeny on WGS data of the clinical isolates, reference isolates and public genome sequences revealed however, that the outbreaks are two independent events and that isolates from both outbreaks diverged at least 20 years before. Our study shows the benefit of WGS in outbreak management in a clinical setting for pathogens for which traditional molecular typing methods lack resolution.

<sup>2</sup>Microbiology, CINVESTAV, Mexico City, Mexico

<sup>3</sup>Fac. Medicina, UNAM, Mexico City, Mexico

<sup>4</sup>UIEIP, IMSS, Mexico City, Mexico

**Background**

Colonization by Enterobacterias takes place in the first hours of life. This event is influenced not only by the surrounding environment, but also by bacterial flora of those in contact with the newborn, and the host conditions. The kind of bacterial flora acquired in this stage of life could influence the development of the newborn in a decisive form.

**Objectives**

To study Enterobacterial colonization process in a cohort of newborns through the identification of the presence of *Escherichia coli* enteropathogenic strains.

**Methods**

Coproscopic cultures of a cohort of newborns were carried out for a period of 24 months where bacterial genus and species were identified through conventional techniques. Enteropathogenic *E. coli* strains were re-identified using Enterotest and were later characterized by Multiplex PCR to identify different types of diarrheogenic *E. coli* and the presence of characteristic genes of each type.

Results. We identified diarrheogenic strains in the samples of the children from the first month of life. Majority of the strains were enteroaggregative (EAEC) type followed by Enterodifuse (DAEC) type which occupied the second place. We did not find association between the types of maternal diarrheogenic *E. coli* and that of the children. Interestingly, the identification of the diarrheogenic types did not have relationship with the presence of diarrhea in the subjects all along the period.

**Conclusions**

The colonization by Enteropathogens seems to be a "normal" event in the studied community without association with diarrheic episodes.

**FEMS-1058**

**INITIAL IDENTIFICATION AND CHARACTERIZATION OF STRAINS OF  
KLEBSIELLA PNEUMONIAE ISOLATES FROM A COHORT OF CHILDREN OF 1 -  
24 MONTHS OLD**

R. Coria Jimenez<sup>1</sup>, B. González-Martínez<sup>1</sup>, M. Ortiz-Herrera<sup>1</sup>, C. Romo-Gonzalez<sup>1</sup>,  
D. Alcántar<sup>2</sup>, C. Ximénez-García<sup>2</sup>, J. Torres-López<sup>3</sup>

<sup>1</sup>Experimental Bacteriology, Instituto Nacional de Pediatría, Mexico City, Mexico

<sup>2</sup>Fac. Medicina, UNAM, Mexico City, Mexico

<sup>3</sup>UIEIP, IMSS, Mexico City, Mexico

**Background**

Bacterial colonization takes place in the first hours of the birth of a baby. Until now, there is a consensus on the fact that newborns are contaminated by the maternal flora, principally when birth is by normal delivery. The Enterobacterias rapidly colonize the gastrointestinal tract, adapt and remain for prolonged periods, usually throughout the life of the individual.

**Objectives**

To follow-up the process of bacterial colonization and adaptation using *Klebsiella pneumoniae* as a model.

**Methods**

64 strains of *K. pneumoniae* isolated from 16 pairs of mother-child during a period of 24 months were studied. Bacterial identification was carried out through conventional techniques while bacterial identity was confirmed by Enterotest system. Also, antibiotic sensitivity tests were performed. Bacterial strains were genotypically characterized using RAPD-PCR and PFGE. PAST Program was employed for the identification of similar groups while the presence of 4 genes that codify bacterial adhesins were identified by means of PCR.

Results. We identified a series of *K. pneumoniae* clones in the children that are not related with the maternal strains. Two colonization patterns by *K. pneumoniae* were found. However, we did not find an association of these patterns with the way of birth (normal or cesarean delivery). It was found that along the period studied, there was population exchange of *K. pneumoniae* in the children studied.

**Conclusions**

In the case *K. pneumoniae*, the colonization of the children is not apparently from their mother and the way of their delivery does not influence in the colonization patterns.

**FEMS-2309**

**NATURALLY OCCURRING VARIANTS OF INVASION FACTORS AND  
POLYHOSTALITY OF LISTERIA MONOCYTOGENES**

S. Ermolaeva<sup>1</sup>, K. Sobyenin<sup>1</sup>, E. Sysolyatina<sup>1</sup>, M. Kurnaeva<sup>1</sup>, Y.A. Chalenko<sup>1</sup>

<sup>1</sup>Infections with natural foci,

Gamaleya Research Institute for Epidemiology and Microbiology, Moscow, Russia

**Background**

The Gram-positive bacterium *Listeria monocytogenes* causes a serious disease in humans and a wide range of animals. Cell invasion is a critical step of listerial infection. Bacterial proteins of internalin family InlA and InlB are critical for invasion of normally non-phagocytosing cells. The previously found correlation between InlA and InlB sequences and a host organism suggested that some naturally occurring variants of invasion factors might facilitate infection of certain hosts for the strains carrying these variants thus providing *L. monocytogenes* polyhostality.

**Objectives**

To test the suggestion that naturally occurring variants of *L. monocytogenes* invasion factors provide higher tropism to certain hosts.

**Methods**

Isogenic recombinant strains were obtained by cloning of *inlB* alleles found in human and animal isolates into the *L. monocytogenes* EGDe $\Delta$ inlB strain. To exclude regulatory effects, *inlBs* were put under the control of the EGDe P<sub>inlAB</sub> promoter and their secretion was driven by a heterologous signaling peptide. Human cells Hep-2 and Hek293 and murine cells C26 were used for the invasion assay.

Totally 8 *inlB* alleles were cloned from human and animal isolates into the same genetic background. The VIMHA004 and the VIMPHk23 *inlB* alleles provided the highest invasion of human and murine cells, respectively. The VIMHA004 and VIMPHk23 variants differed by substitutions Q72H in the N-terminal CAP-domain, N73S, V91I, I138L, P164L in the receptor-binding LRR-domain, T251M in the IR-domain.

**Conclusions**

*L. monocytogenes* InlB variants carrying substitutions in the receptor-binding domain LRR and the CAP and IR-flanking domains demonstrated different efficiency of invasion of human and murine cells.

<sup>3</sup>Faculty of Veterinary Medicine, Ghent University, Merelbeke, Belgium

<sup>4</sup>Faculty of Pharmacy, Ain Shams University, Cairo, Egypt

<sup>5</sup>Faculty of Veterinary Medicine, Mansoura University, Mansoura, Egypt

<sup>6</sup>Foodborne Pathogens, Scientific Institute of Public Health, Brussels, Belgium

<sup>7</sup>Faculty of Veterinary Medicine, Mansoura University, Mansoura, Egypt

**Background**

*E. coli* O157:H7 is one of the most feared zoonotic pathogens that can cause life threatening human disease such as the haemolytic uremic syndrome (HUS). Food sources of animal origin especially cattle, are the main cause of infection but many genotypes exist within this serotype of which their contribution to the clinical outcome of infection in humans is not well known.

**Objectives**

1-Determine the frequencies of distribution of different genotypes among *E. coli* O157:H7 strains recovered from food and human clinical sources using a combination of molecular subtyping methods and assess whether specific genotypes are overrepresented in human clinical strains. 2- Determine the potential correlation of genotype clusters with severe clinical symptoms.

**Methods**

A diverse collection of non-clonal human ( $n=100$ ) and food ( $n=70$ ) isolates from Belgium was characterized by conducting different molecular assays that have previously demonstrated non random distribution of *E. coli* O157:H7 genotypes among clinical and non-clinical isolates: lineage-specific polymorphism assay, Shiga-toxin-encoding bacteriophage insertion site assay, clade typing, *Tir* SNP assay, and variant analysis of Shiga toxin 2 and antiterminator Q genes. Genetic clustering of all data was performed using MCMC model.

**Conclusions**

Our results supported the epidemiological evidence of existence of clinically significant microbial genetic markers that are overrepresented among *E. coli* O157:H7 clinical isolates and which are important determinants of human infection risk. Furthermore, genetic clusters 1 and 3 were observed to be more frequently isolated from bloody diarrhea and haemolytic uremic syndrome, respectively. Our results may contribute to monitoring of genotypes with high virulence/transmission potential.

**DEVELOPMENT OF MICROSATELLITE DNA MARKERS FOR LACHANCEA THERMOTOLERANS**

A. Nisiotou<sup>1</sup>, G. Banilas<sup>2</sup>

<sup>1</sup>ELGO, Institute of Technology of Agricultural Products, Athens, Greece

<sup>2</sup>Department of Enology, TEI of Athens, Athens, Greece

**Background**

*Lachancea thermotolerans* is an important component of the grape/wine ecosystem and one of the first non-*Saccharomyces* yeasts recently commercialised as starter culture in winemaking. Therefore, there is an emerging need for a robust, rapid, and cost effective typing system to be used in ecological and technological studies.

**Objectives**

The complete genome sequence of the *Lachancea thermotolerans* was examined for development of variable number tandem repeat (VNTR) markers suitable in detecting genetic polymorphisms and discriminating among genotypes.

**Methods**

The Tandem Repeats Finder program was applied to detect microsatellites within the *L. thermotolerans* CBS 6340 genome ([www.genolevures.org](http://www.genolevures.org)). After an initial evaluation of potential VNTR markers using standard PCR and agarose gel electrophoresis, 10 markers were retained for further evaluation. Forward primers were labeled with different fluorescent dyes and PCR products were run in an ABI 3730 XLs DNA Analyser.

**Conclusions**

Ten polymorphic VNTR markers were analyzed using 48 *L. thermotolerans* isolates from geographical distant vineyards in Greece. These markers have been carefully selected to be widespread in different chromosomes, so as to be appropriate for phylogenetic analysis. They show a high degree of polymorphism with multiple alleles easily scored, some of which even on agarose gels. Thus, they are quite promising for investigating within and among population variability.

This work is co-financed by the European Regional Development Fund (ERDF) of the EU and by National Resources under the Operational Program Competitiveness and Entrepreneurship (EPAN II), Action "COOPERATION 2011".

**GENETIC INSIGHTS INTO VEGETATIVE COMPATIBILITY GROUPING IN VERTICILLIUM: CHALLENGING THE MYTHS**

I.A. Papaioannou<sup>1</sup>, M.A. Typas<sup>1</sup>

<sup>1</sup>Faculty of Biology Department of Genetics & Biotechnology, University of Athens, ATHENS, Greece

**Background**

*Verticillium dahliae* is a notorious phytopathogenic ascomycete that causes vascular wilt in hundreds of plants worldwide. Classification of isolates into Vegetative Compatibility Groups (VCGs) has been widely used over the past 3 decades as a convenient way to describe population structures and predict pathogenicity potential. This method is based on the general assumption of genetic isolation between VCGs; heterokaryon formation is thus considered possible only between members of the same VCG.

**Objectives**

To test the traditional hypothesis of inter-VCG genetic isolation in *V. dahliae* through genetic investigations and phylogenetic analyses.

**Methods**

(i) Complementation tests using nitrate-nonutilizing (*nit*) and other mutant types of *V. dahliae* isolates, either by the standard procedure performed on minimal medium agar or by a novel high-throughput method in liquid microcultures. (ii) Microscopic investigations of self- and non-self heterokaryon formation between isolates labeled with nuclear fluorescent proteins. (iii) Phylogenetic analysis of a *V. dahliae* collection comprising members of all VCGs, using a highly polymorphic sub-region of the ribosomal IGS region.

**Conclusions**

True heterokaryotic reactions can be forced between *V. dahliae* members of different VCGs by using appropriate mutant types and assay conditions. These heterokaryons are frequently unstable, with uneven distributions of genetically dissimilar nuclei tending to segregate into novel homokaryotic mycelia. Most importantly, inter-VCG heterokaryon formation implies the absence of strict genetic barriers between *V. dahliae* VCGs and/or subgroups. These findings are consistent with the results of phylogenetic analyses of VCGs, which demonstrate a lack of correlation between the VCG classification system and intra-specific genetic groups.

**GENETIC POPULATIONS ANALYSIS OF XYLELLA FASTIDIOSA FROM CITRUS AND COFFEE PLANTS SYMPATRICALLY GROWN IN SAO PAULO STATE, BRAZIL**

C. Sardinha Francisco<sup>1</sup>, P. Cezar Ceresini<sup>2</sup>, H. Della Coletta-Filho<sup>1</sup>

<sup>1</sup>Biotechnology Laboratory, Centro APTA Citros 'Sylvio Moreira' - IAC, Cordeirópolis, Brazil

<sup>2</sup>Plant Health Rural Engineering and Soil, Universidade Estadual 'Julio de Mesquita' - UNESP, Ilha Solteira, Brazil

**Background**

In Brazil *Xylella fastidiosa* (*Xf*) bacteria are responsible by diseases in economically important crops like sweet orange causing the Citrus Variegated Chlorosis and coffee causing the Coffee Leaf Scorch. Population-structure-based studies focusing on the systemic-colonizer, vector-dependent, multi-host plant pathogenic bacterium *Xf* has provided remarkable information about their ecology and biology, specially for the citrus infecting *Xf* populations. In contrast, no information is currently available about the genetic structure of *Xf* populations in coffee and uncertain information are known about the cross infection in citrus and coffee plants by *Xf*.

**Objectives**

To determine the genetic structure of *Xf* populations infecting coffee trees both the genotypic and genetic diversity. Also, assay using cross infection between coffee and citrus strains were realized. Finally, we also like to understand how both hosts and agricultural management has shaped the ecology of both *Xf* populations.

**Methods**

We sampled symptomatic coffee plants from geographic regions sympatric to citrus plantations in Sao Paulo State, Brazil, and isolated hundreds isolates from each region. This isolates were genotyped using 14 genomic microsatellite markers.

**Conclusions**

The coffee-associated *Xf* populations had higher gene diversity and allelic richness than citrus, typical of an evolutionarily older population. Even sharing the same vectors and geographic area *Xf* from coffee and citrus are genetically and biologically different populations with no admixture of strains. *Xf* from coffee were geographically structured similarly as the sympatric populations from citrus. Cross infection were successful only in coffee plants inoculated with *Xf* from citrus, but no colonization were observed after 13 months.

## **L-ASPARTIC ACID CONSUMPTION AS A BASE FOR AMINO ACIDS AND THEIR DERIVATES PRODUCTION BY CORYNEBACTERIUM GLUTAMICUM**

M.F. Vasco-Cárdenas<sup>1</sup>, E. Rubio-Sabugo<sup>1</sup>, M.R. Pérez-Redondo<sup>2</sup>, A. Ibáñez<sup>1</sup>, A. Morales<sup>1</sup>, R.V. Ullán<sup>3</sup>, C. Barreiro<sup>1</sup>

<sup>1</sup>Proteomics, INBIOTEC (Instituto de Biotecnología de León), Leon, Spain

<sup>2</sup>Transcriptomics, INBIOTEC (Instituto de Biotecnología de León), Leon, Spain

<sup>3</sup>Pilot Plant, INBIOTEC (Instituto de Biotecnología de León), Leon, Spain

### **Background**

Corynebacteria are Gram-positive Actinobacteria inhabitants of diverse ecological niches. The most industrial-interesting species is *Corynebacterium glutamicum*, which is involved in amino acids production as pharmaceutical products and mainly as food/feed enhancers. This bacterium produces per year more than 2.93 million tons of L-glutamic acid and 1.95 of L-lysine. However, the coryneform bacteria entered the 21st century with a refocusing of their industrial point of view. Thus, relevant bioproducts such as chemicals and biodegradable polymers, as well as ingredients or additives in food, feed, cosmetics and pharmaceuticals have extended the portfolio of *Corynebacterium* [e. g.: cadaverine].

### **Objectives**

The aspartate pathway is responsible for the biosynthesis of a high number of metabolites of biotechnological importance such as L-lysine, L-threonine, L-methionine and L-isoleucine, as well as other close related compounds: the amino acid L-valine, the vitamin D-pantothenate or the biogenic amine cadaverine (1,5-diaminopentane). The last one is the proof-of-concept compound of the ERA-IB 3<sup>rd</sup> joint call supported project named SCILS (<http://www.era-ib.net/scils>).

### **Methods**

*C. glutamicum* is able to use different alternative nitrogen compounds as L-glutamine or creatinine, but little is known about the possibility of L-aspartic acid utilization. The 2D-DIGE analysis results, as well as a microarrays study of an aspartate-consumption defective mutant, have shown that *C. glutamicum* is able to use L-aspartic acid as nitrogen source.

### **Conclusions**

The bioconversion to different amino acids, which can be the precursor of industrial relevant biomolecules (e.g.: L-lysine decarboxylation yields cadaverine), is the main explanation of the aspartate use.

**A BLUEPRINT OF SULFUR METABOLISM FROM THE PROTEOME OF HYDROGEN-PRODUCER THERMOCOCCUS ONNURINEUS NA1**

Y.J. Moon<sup>1</sup>, J. Kwon<sup>1</sup>, S.H. Yun<sup>1</sup>, S.G. Kang<sup>2</sup>, J.H. Lee<sup>2</sup>, S.I. Kim<sup>1</sup>, Y.H. Chung<sup>1</sup>

<sup>1</sup>Department of Life Science, Korea Basic Science Institute, Daejeon, Korea

<sup>2</sup>Department of Marine Biotechnology,

Korea Institute of Ocean Science and Technology, Ansan, Korea

**Background**

The hyperthermophilic archaeon, *Thermococcus onnurineus* NA1, has been shown to produce biohydrogen (H<sub>2</sub>) when using CO, formate, or starch as a growth substrate. This strain can also utilize elemental sulfur (S<sup>0</sup>) as a terminal electron acceptor for heterotrophic growth and reduce it to H<sub>2</sub>S.

**Objectives**

To gain insight into sulfur metabolism, the proteome of *T. onnurineus* NA1 cells sampled under sulfur culture conditions was quantified and compared with those under formate, CO and starch culture conditions.

**Methods**

Using label-free nano-UPLC-MS<sup>E</sup>-based comparative proteomic analysis, we found that approximately 38.4 % of the total identified proteome (589 proteins) were significantly up-regulated (≥1.5 fold) under sulfur culture conditions.

**Conclusions**

Many of these proteins are functionally associated with carbon fixation, Fe-S cluster biogenesis, ATP synthesis, sulfur reduction, protein glycosylation, protein translocation, and formate oxidation. Our results also revealed markedly lower expression levels of enzymes involved in the sulfur assimilation pathway, as well as cysteine desulfurase under sulfur culture condition. The present results provide a first global atlas of the proteome changes triggered by sulfur. This study will contribute to a better understanding of the mechanisms and physiology of *T. onnurineus* NA1 cells in response to sulphur.

**PROTEOGENOMICS OF THE NUTRITIONALLY VERSATILE, MARINE, SULFATE-REDUCING BACTERIUM *DESULFOCOCCUS MULTIVORANS***

M. Dörries<sup>1</sup>, L. Wöhlbrand<sup>1</sup>, M. Kube<sup>2</sup>, A. Beck<sup>3</sup>, R. Reinhardt<sup>4</sup>, R. Rabus<sup>1</sup>

<sup>1</sup>General and Molecular Microbiology, Universität Oldenburg ICBM, Oldenburg, Germany

<sup>2</sup>Department of Crop and Animal Sciences, Humboldt-Universität zu Berlin, Berlin, Germany

<sup>3</sup>IT, Max-Planck-Institute for Molecular Genetics, Berlin, Germany

<sup>4</sup>MP-GC, Max Planck Genome Centre Cologne, Cologne, Germany

**Background**

Sulfate-reducing bacteria play a major role in marine carbon and sulfur cycling. Members of the metabolically versatile deltaproteobacterial *Desulfococcus/Desulfosarcina*-cluster are abundant in marine sediments and therefore of ecophysiological importance. A metabolically versatile representative of this cluster is *Desulfococcus multivorans* that is able to completely oxidize a variety of organic acids, including fatty acids up to C<sub>14</sub>, as well as aromatic compounds under anoxic conditions.

**Objectives**

Proteomics-enhanced genome annotation of *D. multivorans* was based on cells adapted to 17 different substrate conditions and aimed at metabolic reconstruction and deciphering the regulatory network.

**Methods**

Manual revising of automatically predicted and annotated protein-coding sequences (CDS) was combined with proteomic data (2D-DIGE, shotgun, membrane protein-enriched fraction) of substrate-adapted cells to allow for improved functional prediction.

**Conclusions**

The closed genome sequence consists of a 4.45 Mb circular chromosome with 3946 predicted CDS. The metabolic versatility of *D. multivorans* is reflected by the high number (269) of encoded proteins involved in organic carbon catabolism, 156 of which were detected. Out of the 324 genomically predicted transport proteins 104 could be detected in the membrane protein-enriched fraction. The presence of >200

genes encoding proteins involved in signal transduction should facilitate from the basis of a regulatory network for adapting to changing environmental conditions. Accordingly, out of 1247 identified proteins, only 220 were present under all analyzed substrate conditions, unravelling a high level of substrate-dependent regulation in *D. multivorans*. Overall, the study underpins the value of proteomic analysis to enhance functional genomic predictions, providing new perspectives on our metabolic understanding of sulfate-reducing bacteria.

<sup>2</sup>Head of Environment Division,

Asociación de Investigación INBIOTEC Instituto de Biotecnología de León. Avda. Real 1 - Parque Científico de León 24006. rvicu@unileon.es, León, Spain

**Background**

Fungi are known as active degraders of lignocellulosic materials in nature, soil, compost and forest topsoil. The method for degradation depends on the fungus genus with different results. The key for their degradation capacity resides in the fact that the extracellular enzymes have different capacities more or less active according to the lignocellulosic substrate. These enzymatic extracts are used in biotechnological processes in the industry.

**Objectives**

*Penicillium chrysogenum* B13 strain (CTM2012-32026 project<sup>1</sup>) is an overproducer of feruloyl esterase (FAE) able to hydrolyze the ester bonds between the hydroxycinnamic acids and the plant cell wall polysaccharides. As a result of FAE activity, the polysaccharides are more accessible, allowing complete digestion by the rest of the enzymes involved in the plant cell wall degradation.

**Methods**

*P. chrysogenum* B13 strain was grown in presence of sugar beet pulp and the enzymatic extract secreted to the culture medium was obtained at the time of greatest FAE activity. Two-dimensional gel electrophoresis of proteins was performed and subsequently proteins were identified by means of a MALDI-TOF mass spectrophotometer system.

**Conclusions**

The analysis of the results showed that the FAE activity is increased by 9.27% with respect to the wild strain

*P. chrysogenum* Wisconsin 54-1255 and that 42.22% of the secreted proteins are

enzymes associated with the degradation of plant cell wall, compared to only 11.59% when the culture medium does not contain plant substrate.

<sup>1</sup>The project CTM2012-32026 is funded by Spanish Ministry of Economy and Competitiveness (MINECO) through the Subprogramme for Non-Guided Fundamental Research Projects. 2012.

**Microbial proteomics**

## **IDENTIFICATION OF REDOX PARTNER OF HELICOBACTER PYLORI HP0377 PROTEIN.**

M. Grzeszczuk<sup>1</sup>, A. Lasica<sup>1</sup>, E.K. Jagusztyn-Krynicka<sup>1</sup>

<sup>1</sup>Department of Bacterial Genetics, Institute of Microbiology, Warsaw, Poland

### **Background**

*Helicobacter pylori* is the common human pathogen colonizing the gastric epithelium of humans with severe consequences. HP0377 is a Dsb thiol oxidoreductase which acts as CcmG protein, involved in the maturation of apocytochrome c. CcmG proteins are kept in the reduced form by an integral membrane protein DsbD or its shortened analogue, CcdA. Both proteins catalyze the transfer of electrons from cytoplasmic thioredoxin across the inner membrane to the periplasm. *H. pylori* does not encode DsbD, however it encodes homologue of CcdA (HP0265).

### **Objectives**

The aim of this study was to establish whether HP0265 is responsible for HP0377 rereducing.

### **Methods**

To inactivate *hp0265*, the allelic exchange strategy was used. A recombinant plasmid pUWM2019 (based on a vector non-replicating in *Helicobacter* cells) constructed by a two step PCR method, was used for mutagenesis. It contains the *hp0265* gene disrupted by insertion of a kanamycin resistance cassette into the gene coding sequence. We then tested whether deletion of *hp0265* affects the redox state of HP0377 using AMS trapping strategy. This agent can only modify covalently free thiols, resulting in a molecular mass increase of about 490 Da.

### **Conclusions**

We found that *H. pylori* HP0377 is rereduced by HP0265. Obtaining the *hp0265* mutant was dependent on presence of the reducing agent, DTT. Moreover, the growth of the *hp0265* mutated strain without the presence of DTT was much slower than the growth of wt strain, which indicates the importance of HP0265 and its reducing activity for bacterial survival.

**A METAPROTEOMIC APPROACH FOR ANALYSIS OF MICROBIAL COMMUNITY STRUCTURE AND FUNCTION FOR IMPROVEMENT OF BIOGAS PLANT PERFORMANCE**

R. Heyer<sup>1</sup>, F. Kohrs<sup>1</sup>, D. Benndorf<sup>1</sup>, J. DeVrieze<sup>2</sup>, E. Rapp<sup>1</sup>, N. Boor<sup>2</sup>, U. Reichl<sup>1</sup>

<sup>1</sup>*Bioprocess Engineering, Otto von Guericke University Magdeburg, Magdeburg, Germany*

<sup>2</sup>*Laboratory of Microbial Technology and Ecology, Gent University, Magdeburg, Germany*

**Background**

To avoid downtime in operation and to further optimize operation of biogas plant (BGP) profound understanding of the composition and function of microbial community converting the biomass to methane is required.

**Objectives**

Our main goal is to understand how process conditions determine the process performance, the taxonomic and functional composition of the microbial community and vice versa. For such investigations, the quantification of the composition of the active community is essential. In particular, the presence of key enzymes of metabolic pathway correlates well with the community activity. Thus, the present study investigated the metaproteome of 40 industrial-scale BGPs.

**Methods**

The applied metaproteome workflow involved protein extraction using liquid phenol, tryptic digestion, peptide separation by liquid chromatography coupled to tandem mass spectrometry (Velos Orbitrap Elite), and data analysis with the *MetaProteomeAnalyzer* software [1].

**Conclusions**

For each BGP, about 500 proteins, covering the main metabolic pathways of the biogas process, namely hydrolysis, fermentation, acetogenesis and methanogenesis, were identified. The microbial communities detected by metaproteome analysis of the BGPs clustered according process temperature (mesophilic and thermophilic) [2,3], and substrate composition.

Application of metaproteomics allowed the acquisition of profound knowledge about community structure and function of microbial communities and contribute to our understanding of the conversion of biomass into methane. This knowledge could be used to improve monitoring and control of BGP, and to support development of new BGP designs.

**IDENTIFICATION OF PEPTIDASES GENERATING CONSTITUTIVE  
COLLAGENOLYTIC ACTIVITY OF GEOBACILLUS THERMOLEOVORANS  
DSM15325**

A. Jasilionis<sup>1</sup>, N. Kuisiene<sup>1</sup>

<sup>1</sup>Microbiology and Biotechnology, Vilnius University, Vilnius, Lithuania

**Background**

While the main biological importance of collagen degradation for prokaryotic pathogens is tightly connected with virulence, thermophilic bacteria use collagenolysis when exploit collagen for nutrition. To date the view that collagen catabolism by thermophilic bacteria is a result of a cascade of synergistically active inducible peptidases is prevailing. Usually this model of collagen degradation omits the thermophilic bacteria constitutively produced collagenolytic peptidases. The constitutive collagenolytic activity of thermophilic bacteria was never deliberately analyzed and the understanding of constitutive peptidases importance for collagen hydrolysis *in vivo* is obscure, what reduces the overall fundamental understanding of collagenolysis biological roles for prokaryotes.

**Objectives**

Detect hydrolytic activity of *Geobacillus thermoleovorans* DSM15325 constitutively produced collagenolytic peptidases. Identify detected hydrolases by mass spectrometry.

**Methods**

*G. thermoleovorans* DSM15325 was cultivated in modified M9 medium up to late exponential growth phase when the total secretome proteins were precipitated and analyzed by SDS-PAGE. The evaluation of collagenolytic peptidases activity was performed by gelatin zymography and azocollolysis. Detected peptidases were excised from acrylamide gel and subjected to mass spectrometry analysis. Obtained enzyme sequences were analyzed *in silico*.

**Conclusions**

The Bacillolysin (protein ID AEV20496.1), Pz-peptidase A (protein ID BAD99433.1) and B (protein ID BAD99434.1) were identified as peptidases generating constitutive collagenolytic activity of *G. thermoleovorans* DSM15325.

## **THE MEMBRANE PROTEOM OF CRONOBACTER SAKAZAKII, MALONATICUS AND TURICENSIS**

B. Javůrková<sup>1</sup>, P. Junková<sup>1</sup>, J. Vlach<sup>1</sup>, L. Karamonová<sup>1</sup>, M. Blažková<sup>1</sup>, L. Fukal<sup>1</sup>

<sup>1</sup>Biochemistry and Microbiology, University of Chemistry and Technology Prague, Prague 6, Czech Republic

### **Background**

Bacteria from genus *Cronobacter* are opportunistic pathogens associated with rare but severe infections mainly among neonates. Based on the epidemiological studies and molecular typing methods such as MLST is obvious that *C. sakazakii*, *C. malonaticus* and *C. turicensis* are prevalent in neonatal infections and particularly sequence types ST4, ST7 and ST19 are considered as an attribute of virulence strains.

### **Objectives**

The aim of this study was to map membrane of virulent strains being as the gateway to the host organism and to contribute to the knowledge of virulence features of this genus.

### **Methods**

We applied several techniques for membrane proteins isolation such as the whole cell membrane isolation by phenol extraction method, the membrane sub-fractionation into outer membrane, periplasm and inner membrane, and the immunoprecipitation using polyclonal antibodies against whole *Cronobacter sakazakii* cells. The isolated proteins were consequently identified by mass spectrometry and peptide mass fingerprinting method.

### **Conclusions**

Membrane proteins play a pivotal role in bacterial pathogenesis thus a complex study of membrane proteome of pathogens is invaluable. Here we present membrane proteomes report of the strains considered as pathogenic focusing on virulence traits determination.

**ANALYSES OF ACTIVATED SLUDGE METAPROTEOMES OF A WASTEWATER TREATMENT PLANT DURING WINTER AND SUMMER PERIOD**

F. Kohrs<sup>1</sup>, S. Püttker<sup>1</sup>, D. Benndorf<sup>1</sup>, R. Heyer<sup>1</sup>, E. Rapp<sup>2</sup>, U. Reich<sup>2</sup>

<sup>1</sup>*Bioprocess Engineering, Otto von Guericke University, Magdeburg, Germany*

<sup>2</sup>*Bioprocess Engineering,*

*Max Planck Institute for Dynamics of Complex Technical Systems, Magdeburg, Germany*

**Background**

Molecular biological approaches (i.e. community fingerprinting, metagenome sequencing) revealed that only a small portion of the microbial community typically found in wastewater treatment plants (WWTP) can be cultivated in the laboratory. In order to understand its function without isolating single strains, metaproteomics analysis has been applied to activated sludge samples.

**Objectives**

The impact of changes in temperature (winter and summer period) on metaproteomes of activated sludge samples derived from a full-scale WWTP was investigated to enable a detailed description on functional level.

**Methods**

For reduction of sample complexity prior to MS analysis, different fractionation techniques including reversed phase liquid chromatography (RP-LC), sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE), and liquid isoelectric focusing were combined and compared regarding effort and quality of resulting protein identifications. The derived spectra were identified using the UniProtKB/Swiss-Prot protein database. Additionally, identified KEGG ontologies (Kyoto Encyclopedia of Genes and Genomes) and Enzyme Commission numbers were used to plot proteins hits into pathway maps of the central carbon and nitrogen metabolism.

**Conclusions**

As expected, the high resolving but most time consuming three-dimensional approach yielded the highest amount of protein identifications. The results revealed taxonomic differences in the abundance of specific classes, such as Beta- and Gammaproteobacteria, in activated sludge collected during winter and summer period. Fractions of eukaryotic proteins decreased from winter to summer period, indicating a better degradation performance during summer period due to increasing process temperature. Additionally, more proteins associated to the nitrogen

metabolism, like hydroxylamine dehydrogenase or ammonia monooxygenase, were identified in summer period.

## **CALCIUM-TRYPTOPHAN INTERACTIONS IN CALCIUM-BINDING PROTEINS**

P. Matyska Liskova<sup>1</sup>, R. Fiser<sup>1</sup>, L. Bumba<sup>2</sup>, I. Konopasek<sup>1</sup>

<sup>1</sup>*Department of Genetics and Microbiology,*

*Charles University in Prague Faculty of Science, Prague 2, Czech Republic*

<sup>2</sup>*Institute of Microbiology, The Academy of Sciences of the Czech Republic,  
Prague 4, Czech Republic*

### **Background**

Calcium ion is the important structural element in bacterial cells and is also involved in cell signaling. Also, the calcium binding may enable protein folding and enzymatic activity. Aromatic amino-acids in proteins can stabilize the native protein structure via pi-pi interactions and may also play a role in calcium binding by cation-pi interactions. Terbium (Tb<sup>3+</sup>) is the phosphorescent lanthanide that may be used as a calcium binding analog. Tb<sup>3+</sup> increases the quantum yield as it binds to calcium binding sites (in proteins, DPA), which enables spectroscopic ion binding measurements. In our previous studies of FrpC protein of *Neisseria meningitidis* we found the calcium binding as a driving force for FrpC folding. The two Trp residues of FrpC also play an important role as stabilizing factor in calcium binding and enzymatic activity, the auto-catalytic cleavage.

### **Objectives**

In order to estimate the importance of calcium-Trp interactions in proteins, we analyzed PDB crystal structures possessing both Trp residues and bound calcium.

### **Methods**

In all calcium-containing-protein-structures in PDB (n=6403) relative Ca/Trp positions were analyzed (392000 cases). FrpC studies: Steady-state fluorescence spectroscopy.

### **Conclusions**

We confirmed that in calcium-binding enzymatic domain of FrpC, calcium is bound in the close proximity to Trp residues that supports the calcium-Trp interaction. Using PDB database search, we found that such calcium-Trp position is rather rare among protein structures and that calcium is most frequently positioned toward nitrogen hetero-atom in indol.

**Microbial proteomics**

**QUANTITATIVE SHOTGUN PROTEOMIC APPROACH FOR THE STUDY OF S.COELICOLOR M145 AND S.LIVIDANS TK24, TWO PHYLOGENETICALLY CLOSELY RELATED STRAINS WITH VERY DIFFERENT ABILITIES TO PRODUCE ANTIBIOTICS**

A. Millan-Oropeza<sup>1</sup>, C. Henry<sup>2</sup>, M.J. Virolle<sup>1</sup>, A. Aubert-Frambourg<sup>2</sup>

<sup>1</sup>*Métabolisme Energétique des Streptomyces, Institut de Biologie Intégrative de la Cellule (I2BC) de l'Université Paris Sud, Orsay, France*

<sup>2</sup>*Micalis - PAPPSO, Institute National de la Recherche Agronomique (INRA), Jouy en Josas, France*

**Background**

*Streptomyces* are filamentous Gram positive soil bacteria of industrial interest due to their ability produce two-thirds of all known antibiotics as well as other so-called "secondary metabolites" useful to human health or agriculture. A reverse correlation between the content in TriAcylGlycerol (TAG) and the ability to produce antibiotics was recently demonstrated. In the presence of glucose, the lipid content of *S. coelicolor* is less than 10% its dry cell weight (DCW) indicating that its TAG content is very low and abundantly produces antibiotics whereas the total lipid content of *S. lividans* is up to 30% its DCW and does not produce antibiotics. Interestingly, in the presence of glycerol, the two strains have the same lipid content (about 30% of their DCW).

**Objectives**

In order to understand the molecular basis of these phenotypical differences between these two *Streptomyces* species, we developed a novel gel-free shotgun proteomic approach.

**Methods**

This strategy involves a simple protein extraction followed by proteolysis in presence of trypsin and LysC and LC-MS/MS analysis by Q-exactive MS (Thermo Fisher). We performed a three-factor analysis of variance that included: strain factor (*S.lividans/S.coelicolor*); carbon source factor (glucose/glycerol), and time factor (36h/48h/72h).

**Conclusions**

More than 2500 proteins were identified corresponding approximately to 30% of the genome. This study showed different pattern of expression of genes of central carbon and lipids metabolism as well as antibiotics biosynthesis, upon growth on glucose or glycerol. These results revealed some potentially interesting genes to be genetically modified for further improvement of antibiotics and/or TAG production by *Streptomyces* species.

**THE SMALL PROTEIN SCO2038 CONTROLS STREPTOMYCES COELICOLOR DIFFERENTIATION BY MODULATING TRYPTOPHAN BIOSYNTHESIS**

E. Palazzotto<sup>1</sup>, G. Gallo<sup>2</sup>, P. Fontana<sup>2</sup>, A. Sutura<sup>2</sup>, G. Renzone<sup>3</sup>, A. Giardina<sup>2</sup>, J. Silva<sup>2</sup>, C. Vocat<sup>2</sup>, A. Fabbretti<sup>1</sup>, A. Scaloni<sup>3</sup>, A.M. Puglia<sup>2</sup>

<sup>1</sup>*School of Biosciences and Veterinary Medicine, University of Camerino, Camerino, Italy*

<sup>2</sup>*STEBICEF, University of Palermo, Palermo, Italy*

<sup>3</sup>*ISPAAM, National Research Council, Napoli, Italy*

**Background**

In *Streptomyces coelicolor* amino acid metabolism is an important clue of the morphological and physiological differentiation program and, differently from other bacteria, the expression of amino acid biosynthetic genes is not subjected to end-product negative regulation. In some amino acid biosynthetic gene clusters, such as tryptophan, histidine and proline, small orfs (about 100-300 nucleotides) were identified. These small orfs, such as sco2038, encode proteins whose cellular role have to be elucidated to highlight possible novel and crucial molecular mechanisms controlling amino acid synthesis and, thus, differentiation program.

**Objectives**

The aims of this work are:

1. the understanding of the effects exerted by tryptophan on primary metabolism, morphological differentiation and antibiotic production;
2. the study and characterization of the SCO2038 function as modulator of tryptophan biosynthesis.

**Methods**

- Differential proteomic analysis based on 2D-DIGE and MS procedures.
- SEM analysis.
- Generation and characterization of sco2038 mutants
- Identification of potential SCO2038 interaction partners by pull down assay coupled with MS identification and Bacterial Adenylate Cyclase Two Hybrid System.
- qRT-PCR analysis.

**Conclusions**

The obtained results revealed that tryptophan controls the expression of metabolic and regulatory proteins and promotes aerial mycelium formation, spores production and actinorhodin antibiotic biosynthesis. Moreover, the small orf sco2038, encodes a 7 KDa protein playing a key role in modulating tryptophan biosynthesis and thus, morphological differentiation. In the light of these results we propose to rename sco2038 as *trpM*, the gene encoding the tryptophan biosynthesis Modulator TrpM.

## **SLP PROFILES IN ENDEMIC AND NON-ENDEMIC CLOSTRIDIUM DIFFICILE PCR-RIBOTYPES**

*M. Bistan*<sup>1</sup>, *T. Rikanovic*<sup>2</sup>, *M. Rupnik*<sup>3</sup>

<sup>1</sup>*Department of microbiology, Faculty of Medicine University of Maribor, Maribor, Slovenia*

<sup>2</sup>*Cipkebip,*

*Centre of Excellence for Integrated Approaches in Chemistry and Biology of Proteins, Ljubljana, Slovenia*

<sup>3</sup>*Department for microbiological research,*

*National Laboratory for Health Environment and Food & Faculty of Medicine University of Maribor & Cipkebip, Maribor, Slovenia*

### **Background**

*Clostridium difficile* is divided into approximately 400 PCR-ribotypes, some of them are widespread and associated with severe disease. *C. difficile* PCR-ribotypes 014/020 and 002 are the most common among endemic PCR-ribotypes.

Many bacteria, including *C. difficile*, express surface layer protein (Slp). This protein forms surface-exposed proteinaceous layer which mediates interactions with the external environment, i.e. adhesion to host cells as in case of *C. difficile*. Two Slp proteins with molecular weights (MWs) of 32-38 kDa (low MW) and 42-48 kDa (high MW) are expressed and vary in size in different *C. difficile* strains. Slp typing is described, but not widely used.

### **Objectives**

The aim of the study was to compare slp profiles of two endemic PCR-ribotypes (014/020 and 002) and selection of non-endemic PCR-ribotypes.

### **Methods**

Eighty-eight *C. difficile* isolates from 21 different PCR-ribotypes were included. Extraction of Slp proteins was performed by using low-pH glycine solution and further analyzed by SDS-PAGE.

### **Conclusions**

Five different slp profiles (1-5) were identified. Slp profiles 1 and 2 were the most frequent and present in the majority of PCR-ribotypes. Endemic and non-endemic

PCR-ribotypes shared 3 out of 5 slp profiles. Two remaining slp profiles were present only in one strain each.

Our results indicate that slp profile does not contribute significantly to *C. difficile* colonization properties and endemicity.

## **FLUORESCENT BIOMARKERS FOR MEMBRANE SEPARATION**

A. Ruud Winther<sup>1</sup>, J.C. Leo<sup>1</sup>, D. Linke<sup>1</sup>

<sup>1</sup>Department of biosciences, University of Oslo, Oslo, Norway

### **Background**

The aim of the project is to develop biomarkers to help distinguish between the inner and the outer membrane of *Escherichia coli*. The fluorescent proteins mCherry, *E. coli* Flavin binding Fluorescent Protein and superfolder GFP, were used as biomarkers. These were directed to the inner or outer membrane using signal sequences from lipoproteins or by fusion with membrane proteins. The fusion partners were the outer membrane protein A (OmpA), the artificial TAT-lipobox signal sequence for transport to and lipid anchoring in the outer membrane, the major coat protein of phage pf3 that is inserted into the inner membrane, and mistic, a integral inner membrane protein from *Bacillus subtilis*.

### **Objectives**

The aim of the project is to develop a bacterial strain (*E.coli* BL21 DE3) with optimized expression levels of the fluorescent markers for co-localization studies of bacterial membrane proteins.

### **Methods**

The methods used in the project include molecular biology (cloning, PCR), microbiological (culturing, recombinant protein expression) and biochemical (cell fractionation, membrane isolation) techniques. In addition, the project will also use analytical methods such as fluorometry and fluorescence microscopy.

### **Conclusions**

The fluorescent marking of the two membranes makes membrane fractions easier to detect after membrane separation. It also help to assess the quality of the separation procedure.

**CHARACTERISATION OF THE BSA TYPE THREE SYSTEM SECRETOME OF BURKHOLDERIA PSEUDOMALLEI USING HYPER-SECRETING MUTANTS**

J. Stevens<sup>1</sup>

<sup>1</sup>*Infection & Immunity, The Roslin Institute, Edinburgh, United Kingdom*

**Background**

Many Gram-negative bacteria utilise Type III secretion systems (T3SS's) to deliver effector proteins into target host cells where they hijack cellular processes for their own benefit. T3SS's form an injectosome with proteins spanning both membranes of the bacterium and an external needle through which effector proteins are delivered into the target cell. *B. pseudomallei*, the causative agent of the tropical disease melioidosis in humans and animals, possesses three distinct T3SS's, of which the Bsa system has been shown to play a role in invasion of non-phagocytic cells, escape from the endocytic compartment and virulence in murine models of melioidosis. To date few proteins have been proven to be secreted by the Bsa apparatus and, by analogy with other pathogens that deploy T3SS's, it is likely that there are many other effectors awaiting discovery

**Objectives**

To characterise the total secretome of *B. pseudomallei* in standard laboratory media and the repertoire of Bsa-secreted effector proteins.

**Methods**

We have determined the effector secretome of the Bsa T3SS using hyper-secreting mutants of coupled with iTRAQ, a gel free quantitative proteomics technique.

**Conclusions**

Our study provides one of the most comprehensive core secretomes of *B. pseudomallei* described to date and identified 26 putative Bsa-dependent secreted proteins that may be considered candidate effectors.

**THE EXCRETORY/SECRETORY PROTEOME OF TRICHOMONAS VAGINALIS  
INDUCED BY NEUTROPHIL**

P. Tang<sup>1</sup>, R.M. Chen<sup>1</sup>

<sup>1</sup>Dept. of Parasitology, Chang Gung University, Taoyuan, Taiwan

**Background**

The protist parasite *Trichomonas vaginalis* causes one of the most common non-viral sexually transmitted disease in humans, trichomoniasis. Previous studies indicate that neutrophils, leukotriene B<sub>4</sub> (LTB<sub>4</sub>) and interleukin-8 (IL-8) are found in the vaginal discharges and vaginal smears of patients infected with *T. vaginalis*.

**Objectives**

IL-8 is often associated with inflammation, also known as neutrophil major chemotactic factor, causing them to migrate toward the site of infection by *T. vaginalis* and start innate immune response to defense. Previous studies focused on the profiling of chemoattractants from neutrophils stimulated by *T. vaginalis* or *T. vaginalis* ESPs, but very little is known about the cell-cell interaction between *T. vaginalis* and neutrophil. We hypothesize that both *T. vaginalis* ESPs and direct contact with neutrophil can induce the release of chemoattractants in the vagina.

**Methods**

In this study, we confirmed that both *T. vaginalis* and ESPs can induce neutrophil to release IL-8. We also used 2-Dimensional SDS-PAGE to investigate the differentially expressed ESPs from *T. vaginalis* before and after contact with neutrophil. A total of 16 differentially expressed protein spots were identified by MALDI-TOF-MS, and discussed the possible roles of identified proteins in the biology of host-parasite interactions.

**Conclusions**

We established a representative 2-DE map of ESPs of *T. vaginalis* induced by neutrophil and identified differentially expressed protein that may promote cytoadherence and long-term colonization while ESPs from neutrophil may be related to implicate in the first line of host defense.

**COMPARATIVE PROTEOMICS ANALYSIS FOR THE IDENTIFICATION OF TARGETS OF THE TMK1 MAP KINASE IN THE MYCOPARASITIC FUNGUS TRICHODERMA ATROVIRIDE**

S. Zeilinger<sup>1,4</sup>, A. Nemes<sup>1</sup>, M. Marchetti-Deschmann<sup>2</sup>, D.P. Kreil<sup>3</sup>, S. Gruber<sup>1</sup>

<sup>1</sup>Biotechnology and Microbiology,

Vienna University of Technology Institute of Chemical Engineering, Vienna, Austria

<sup>2</sup>Institute of Chemical Technologies and Analytics, Vienna University of Technology, Vienna, Austria

<sup>3</sup>Chair of Bioinformatics, University of Natural Resources and Life Sciences, Vienna, Austria

<sup>4</sup>Institute of Microbiology, University of Innsbruck, Innsbruck, Austria

**Background**

Mycoparasitic species of the filamentous fungus *Trichoderma* are commercially applied as biological control agents against fungal plant pathogens. The mycoparasitic interaction of *Trichoderma* with the host fungus comprises specific recognition events leading to activation of "molecular weapons" in the mycoparasite which are involved in host attack and lysis and result in utilization of the host fungus as a nutrient source for the mycoparasite.

Investigations on the underlying intracellular signal transduction pathways of *Trichoderma atroviride* revealed the involvement of a Mitogen-activated protein kinase (MAPK) which is essential for triggering the mycoparasitic Response. Mutants missing the *tmk1* gene show reduced mycoparasitic activity against host fungi.

**Objectives**

The aim of the presented study was the identification of target proteins being regulated by the Tmk1 MAPK pathway upon host recognition. To this end, *T. atroviride* wild-type and the delta-*tmk1* mutant were co-cultivated with the host fungus *Rhizoctonia solani* and *Trichoderma* mycelia were harvested from the confrontation zone upon direct interaction between the two fungi and from respective un-induced (self-confrontation instead of confrontation with the host) controls.

**Methods**

Two-dimensional Difference Gel Electrophoresis (2-D DIGE) was applied for comparatively analysing the proteomes of the four samples with the aim to find mycoparasitism-relevant targets of the Tmk1 MAPK.

## Conclusions

Bioinformatic analyses revealed 60 proteins being regulated in the wild-type response (WT vs. *R. solani* minus WT vs. WT) and 126 proteins being host-induced Tmk1 targets (WT vs. *R. solani* minus delta-*tmk1* vs. *R. solani*), of which 30 and 60 proteins, respectively, were identified by mass spectrometry.

#### **PROTEOMICS ANALYSIS OF THE *B. SUBTILIS* INNER SPORE MEMBRANE**

L. Zheng<sup>1</sup>, W. Abhyankar<sup>1</sup>, N. Ouwerling<sup>1</sup>, H.L. Dekker<sup>2</sup>, W. Roseboom<sup>2</sup>,  
L.J. de Koning<sup>2</sup>, S. Brul<sup>1</sup>, C.G. de Koster<sup>2</sup>

<sup>1</sup>Molecular Biology & Microbial Food Safety, University of Amsterdam, Amsterdam, Netherlands

<sup>2</sup>Mass Spectrometry of Biomacromolecules, University of Amsterdam, Amsterdam, Netherlands

### **Background**

The endospore is the dormant form of *Bacillus subtilis* and many other Firmicutes. By sporulation these spore formers can survive very harsh physical and chemical conditions. Yet they need to go through germination to return to their growing form. The spore inner membrane (IM) has been shown to play an essential role in triggering the initiation of germination; however, its protein composition was not comprehensively characterized yet.

### **Objectives**

To isolate IM from *B. subtilis* spores and to characterize the *B. subtilis* spore IM proteome.

### **Methods**

The spores were chemically decoated and enzymatically deprived of the cortex. Subsequently the core was mechanically disrupted and the IM fraction was collected by differential centrifugation. Tryptic peptides, acquired from in-gel digestion, were analyzed using Ion trap LC-MS/MS, which led to identification of the spore IM proteins.

### **Conclusions**

We have adapted the spore IM isolation protocol to proteomics studies. Over 900 proteins could be identified from the *B. subtilis* spore IM preparations, in which ca. one-third were predicted to be membrane proteins. In addition to the previously known IM proteins, a number of novel IM proteins were identified which are likely to provide new insights into the IM protein composition, its functions and in particular into the spore germination machinery.

**PARTIAL NUCLEOTIDE SEQUENCE OF THREE RESISTANCE PLASMIDS OF PSYCHROTOLERANT ENTEROBACTERIA ISOLATED FROM FILDES PENINSULA, KING GEORGE ISLAND (MARITIME ANTARCTICA)**

V. ANTELO<sup>1</sup>, D. MAZEL<sup>2</sup>, S. BATISTA<sup>1</sup>

<sup>1</sup>Unidad de Microbiología Molecular,  
Instituto de Investigaciones Biológicas Clemente Estable, Montevideo, Uruguay

<sup>2</sup>Unité Plasticité du Génome Bactérien Département Génomes et Génétique,  
Institut Pasteur, Paris, France

**Background**

The presence of plasmids carrying class 1 integrons in a collection of psychrotolerant enterobacteria isolated from Fildes Peninsula was previously established. In these plasmids, we could identify a DNA region with three ORFs (*intl1*, *dfrA14* and *hyp*, encoding a hypothetical protein) highly similar to a fragment originally identified in plasmid pKOX105 from *Klebsiella oxytoca* (HM\_126016).

**Objectives**

DNA sequence analysis of plasmids purified from some of these enterobacterial isolates.

**Methods**

Plasmid DNA from isolates CDTR5, CN11 and HP19 were purified with Gene Plasmid Midprep Elute® HP (Sigma-Aldrich Co, MO) and sequenced in a Ion 314™ Chip on a Ion PGMTM System (Life Technologies,) at the IIBCE. The reads were assembled using CLC Genomics Workbench v6.5 (CLC bio). Annotation of pHP19 contigs and comparison with plasmids pECL\_A and pKOX105 were done using RAST server (<http://rast.nmpdr.org/rast.cgi>).

**Conclusions**

Sequence analysis of pHP19 showed a region of 7181 nts highly similar (99% identity by Blastn) with a region of pKOX105 (54641pb). This contig includes the *intl1* gene and other ORFs encoding a DNA-cytosine methyltransferase and a probable membrane protein.

The sequences of other plasmidic regions were similar to those of *Enterobacter cloacae* ATCC 13047 plasmid pECL\_A (IncFII) (199562pb) (NC\_014107), including genes for replication, stability and conjugation. Other cluster genes related with mercury, arsenic, tellurite, nickel and copper resistance identified were identical to those found in pECL\_A. Thus this plasmid is likely a mosaic of portions of plasmids

that have been characterized in mesophilic enterobacteria, showing that HGT between these bacteria and the Antarctic microbiota is rather common.

**Mobile genetic elements**

## **C-DI-GMP CONTROL MODULES CONFINED WITHIN MOBILE ELEMENTS: THE CASE OF ICEAca<sub>TY.2</sub>**

M. Castro<sup>1</sup>, L. Acuña<sup>1</sup>, M.I. von Unger<sup>2</sup>, N. Guilian<sup>3</sup>, R. Quatrini<sup>1</sup>

<sup>1</sup>*Microbial Ecophysiology Laboratory, Fundación Ciencia & Vida, Santiago, Chile*

<sup>2</sup>*Facultad de Ciencias Biológicas, Universidad Andres Bello, Santiago, Chile*

<sup>3</sup>*Department of Biology Laboratory of Bacterial Communication, Faculty of Sciences University of Chile, Santiago, Chile*

### **Background**

The intracellular nucleotide c-di-GMP has recently emerged as one of the central elements of the signal transduction network linking perception of environmental or intracellular cues to specific alterations in cellular function. In response to different input signals, the opposing activities of diguanylatecyclases (DGCs) and phosphodiesterases (PDEs) control the cellular concentration of c-di-GMP. Inside the cell, c-di-GMP binds a currently unknown number of effector molecules that subsequently interact with cognate target components to produce a variety of output phenotypes (e.g. transition from planktonic to biofilm). Given the multiplicity of c-di-GMP related genes in most bacterial genomes and their scattered distribution within the genomes, the elements that belong to the same c-di-GMP control module are difficult to uncover.

Recently, an integrative conjugative element -ICEAca<sub>TY.2</sub>- has been characterized in the extreme acidophile *Acidithiobacillus caldus* ATCC 51756. ICEAca<sub>TY.2</sub> is an actively excising element of widespread occurrence in a collection of *At. caldus* strains, that behaves as a cohesive heritable unit. Bioinformatic analysis of ICE.2-type elements has revealed that c-di-GMP synthesis/degradation functions and putative c-di-GMP binding effectors and targets co-occur within the element.

### **Objectives**

To gain insight into the participation of c-di-GMP genes encoded by ICEAca<sub>TY.2</sub> as a functional control module.

### **Methods**

To test this hypothesis the expression of the c-di-GMP genes encoded by ICEAca<sub>TY.2</sub> was quantified by real-time PCR under different growth conditions (e.g. planktonic, attached, stressed).

### **Conclusions**

Transcriptional behavior of key c-di-GMP module components in attached cells and upon DNA damaging conditions support the hypothesis and further suggest that this control module could be critical for biofilm development and DNA exchange.

## **ENVIRONMENTAL ISOLATES OF *V. PARAHAEMOLYTICUS* CARRY SXT/R391 INTEGRATIVE CONJUGATIVE ELEMENTS**

D. Ceccarelli<sup>1</sup>, M. Spagnoletti<sup>2</sup>, A. Huq<sup>1</sup>, R.R. Colwell<sup>1</sup>

<sup>1</sup>Maryland Pathogen Research Institute, University of Maryland, College Park, USA

<sup>2</sup>Department of Genetics Evolution & Environment, University College London, London, United Kingdom

### **Background**

SXT/R391 Integrative conjugative elements (ICEs) are self-transmissible mobile genetic elements able to confer adaptive features to bacterial hosts, including *Vibrionaceae*. They share a conserved genetic scaffold encoding their own conjugation, integration, excision, and regulatory machinery, interspersed with variable DNA clusters located in conserved hotspots.

### **Objectives**

*In silico* analysis of 96 *V. parahaemolyticus* genomes was performed to identify Integrative Conjugative Elements (ICEs) of the SXT/R391 family.

### **Methods**

Four novel ICEs were detected in environmental non-pandemic *V. parahaemolyticus* strains isolated in China, Spain, and Malaysia (2002-2008). ICE sequences were annotated using the RAST annotation pipeline and comparative analysis was performed with the Artemis Comparative Tool, BLASTN and BLAST-PSI. Given their unique genetic contents they were named: ICE *VpaSpa1* (~111 kb), ICE *VpaMal1* (~70 kb), ICE *VpaChn4* (~66 kb), ICE *VpaChn5* (~86 kb). We identified gene sequences from other ICEs as well as unique genetic features such as a set of heat-shock proteins and chaperones likely to respond to environmental stress (ICE *VpaSpa1*); genes with transpeptidase domains belonging to the beta-lactamase TEM family (ICE *VpaSpa1*); putative type 1 restriction/modification systems (ICE *VpaChn5*, ICE *VpaSpa1*); type III restriction-modification systems (ICE *VpaMal1*); *ars* operon encoding an efflux system mediating arsenic resistance (ICE *VpaMal1*, ICE *VpaChn4*); and an antibiotic resistance cluster carrying *floR*, *strAB* and *sul2* genes (ICE *VpaChn5*).

### **Conclusions**

*V. parahaemolyticus* ICEs exhibit significant genetic polymorphisms, sign that the structure of each ICE has been shaped by frequent recombination, with genetic

content likely dependent on the specific locale in the environment from which it was originally isolated.

## **OBTENTION OF HYPERACTIVE INTEGRASES BY EVOLVING SYNONYMOUS GENES**

J. Escudero<sup>1</sup>, A. Nivina<sup>1</sup>, A. Babic<sup>1</sup>, C. Loot<sup>1</sup>, D. Mazel<sup>1</sup>

<sup>1</sup>*Genomes et Genetique, Institut Pasteur, Paris, France*

### **Background**

Integrans are gene recruitment platforms that allow for rapid bacterial evolution, playing a major role in the acquisition of antimicrobial resistance genes. The integrase catalyzes the reaction between *attC* and *attI* sites. However, its activity is finely tuned to preferentially process *attI* x *attC* and *attC* x *attC* reactions, as they allow for the acquisition and rearrangement of cassettes, rather than the *attI* x *attI* reaction. Being a less frequent phenomenon, the structural basis of *attI* recognition has yet remained elusive.

### **Objectives**

We have conducted directed evolution experiments on the integrase to obtain hyperactive mutants for the *attI* x *attI* reaction. In order to explore a broader evolutionary landscape of the integrase we have recoded the protein into two alternative, yet synonymous, alleles of the *intI1* gene.

### **Methods**

In a first round of experiments we obtained among the three alleles 8 mutations conferring an increase in recombination rates. We reinserted all mutations into the three wt alleles, obtaining a 100-fold increase in recombination efficiency. Re-evolving these alleles yielded new mutants with recombination rates for *attI* x *attI* comparable to those of the wild type protein for the *attI* x *attC* reaction. Along these experiments we obtained landscape-specific mutations and the re-evolution of a codon to a residue beyond its evolutionary landscape in any of the three starting alleles.

### **Conclusions**

We have successfully explored an enlarged evolutionary landscape of the integrase allowing us to obtain hyperactive molecules, while shedding light on the structural features that are important for the recognition of the *attI* site.

**CONJUGATIVE TYPE IVB PILUS RECOGNIZES LIPOPOLYSACCHARIDE  
STRUCTURE OF RECIPIENT CELLS TO INITIATE PAPI-1 PATHOGENICITY  
ISLAND TRANSFER IN PSEUDOMONAS AERUGINOSA**

P.T. Hong<sup>1</sup>, S. Casonato<sup>1</sup>, S. Lory<sup>2</sup>, O. Jousson<sup>1</sup>

<sup>1</sup>*Centre for Integrative Biology, University of Trento, Trento, Italy*

<sup>2</sup>*Department of Microbiology and Immunobiology, Harvard Medical School, Boston, USA*

**Background**

Horizontal gene transfer is an important mechanism in *Pseudomonas aeruginosa* for adapting to a wide range of environments and, in particular, for acquiring virulence determinants which are mostly carried on pathogenicity islands. One of the largest pathogenicity island of *P. aeruginosa* is PAPI-1, a 108-kb island which is known to be transferred from a donor to a recipient strain through a type IVb pilus. However, the PAPI-1 acquisition mechanism has not been elucidated to date.

**Objectives**

We aimed at investigating the mechanism of PAPI-1 acquisition in recipient cells.

**Methods**

To determine the receptor for conjugative type IVb pilus, a standard PAPI-1 transfer assay described by Carter et al. (2010) was carried out using PA14TnC2 as a donor and 38 PAO1 mutants with an altered lipopolysaccharide (LPS) biosynthesis pathway as recipients. The loss of receptor for conjugative type IVb pilus in PAO1 mutants can result in a significant decrease of PAPI-1 transfer. The conjugative pilus receptor was then confirmed with a competition assay by adding outer-membrane and LPS preparations into the standard mating assay.

**Conclusions**

Transfer efficiency of PAPI-1 to the *AlgC* mutant producing a truncated LPS core was reduced by three orders of magnitude compared to that of wild-type PAO1, indicating that LPS acts as a receptor for conjugative type IVb pilus. The homopolymer of D-rhamnose, or rhamnan structure was confirmed as a specific receptor for conjugative type IVb pilus. Further investigation will define if *P.aeruginosa* that have acquired

PAPI-1 specify a surface exclusion mechanism by LPS modification preventing further recognition by conjugative pilus.

<sup>1</sup>*Biologie des bactéries intracellulaires (BBI), Institut Pasteur CNRS UMR3525,  
PARIS Cedex 15, France*

<sup>2</sup>*Unité de Biologie des Bactéries pathogènes à Gram-positif, Institut Pasteur,  
PARIS Cedex 15, France*

<sup>3</sup>*Legionella Pathogenesis Team, Université de Lyon, Lyon, France*

**Background**

Horizontal gene transfer (HGT) and mobile genetic elements (MGEs) are major generators of genome plasticity and diversity. Certain of these elements can exist in the *Legionella pneumophila* (*Lp*) genome in an excised or integrated form and encode for type IV secretion systems (T4SS) and/or conjugation systems. Intriguingly, each of these elements encodes a homologue of CsrA (carbon storage regulator). CsrA is a global regulator of virulence in *L.p*. The Lvh-region is one of these MGEs encoding a T4ASS and a CsrA homologue.

**Objectives**

Deciphering the mechanisms of mobility of the Lvh

**Methods**

Distribution of the Lvh was analyzed by comparative genomics of 50 *L.p* strains, the mobility and regulation of transfer were analyzed by mutagenesis, conjugation experiments, Q-PCR, RNA-Seq and whole genome sequencing of the transconjugants

**Conclusions**

The Lvh mobility is mediated by a phage-like integrase. It is transferable at a rate of  $10^{-4}$  and inserts specifically in the *tmRNA* gene in all analysed transconjugants. Using a  $\Delta dotA$  strain we show that the Dot/Icm T4SS is implicated in the conjugation of the *lvh*-region, as the transfer rate drops to  $10^{-7}$ . Conjugation experiments in a  $\Delta ihf$  mutant (Integration host factor), a nucleoid-associated protein revealed its role in the mobility of the Lvh. Most interestingly the putative RNA-binding protein LvrC (CsrA homologue) affects the mobility of Lvh by conjugation in specific growth conditions. Thus, The mobility of the predicted self-transmissible Lvh-genomic island is regulated by a complex network of global (IHF) and specific regulatory proteins (LvrC) and depends largely on the Dot/Icm T4SS

#### **STRUCTURE AND PROPERTIES OF PLASMIDS ISOLATED FROM ANCIENT ACINETOBACTER LWOFFII STRAINS, THEIR ROLE IN HORIZONTAL GENE TRANSFER OF ANTIBIOTIC AND HEAVY METAL RESISTANCE GENES**

A. Kurakov<sup>1</sup>, M.A. Petrova<sup>1</sup>, N.A. Scherbatova<sup>1</sup>, A. Mardanov<sup>2</sup>, A.V. Beletsky<sup>2</sup>, S.Z. Mindlin<sup>1</sup>

<sup>1</sup>*Molecular Genetics of the Cell,*

*Institute of Molecular Genetics Russian Academy of Sciences, Moscow, Russia*

<sup>2</sup>*Systems Biology, Centre 'Bioengineering' Russian Academy of Sciences, Moscow, Russia*

### **Background**

Three ancient *Acinetobacter lwoffii* strains were aseptically isolated from East-Siberian permafrost sediments and carbon-14-dated to 15.000-30.000 years and 2-3 million years before present.

### **Objectives**

Investigate the structure and properties of plasmids from ancient *Acinetobacter lwoffii* strains, and the presence of various heavy metal and antibiotic resistance genes on those plasmids.

### **Methods**

Complete genomic sequences (average coverage >30) of three strains were obtained using pyrosequencing method. 13 plasmid sequences were assembled and manually analysed using bioinformatics software and public databases and verified with PCR amplification of regions where ambiguous results occurred.

### **Conclusions**

Each strain carried at least two plasmids with their sizes varied between 6 kb and 287 kb. Three largest plasmids designated pKLH208 (287 kb), pKLH211 (190 kb) and pKLH220 (130 kb) belonged to ED23-35, ED45-23 and VS15 strains respectively. Each of these plasmids encoded similar replication and segregation systems and 12 to 18 IS-elements of IS1, IS4, IS5, IS6 and IS66 families with almost twice as many IS-elements with interrupted *tnp* genes, suggesting frequent transposition processes. Apart from two different mercury resistance operons found only on pKLH208 and pKLH211, large plasmids encoded operons conferring resistance to cobalt, zinc, cadmium, chrome and arsenical compounds, several copies of copper and iron intake regulating operons, urea degrading operons, *aadA* (streptomycin/spectinomycin) and *tetA-tetR* (tetracycline) antibiotic resistance genes. We found that 11 of 13 identified plasmids, including two large plasmids pKLH208 and pKLH220, encoded either

mobilisation or conjugation and type IV secretion systems and are potentially capable of transferring horizontally.

**COMPARISON OF INTEGRON ATT<sub>C</sub> SITES: THEIR STRUCTURAL FEATURES DIFFERENTIALLY INFLUENCE THE FREQUENCY AND ORIENTATION OF CASSETTE INTEGRATION**

A. Nivina<sup>1</sup>, J.A. Escudero<sup>1</sup>, D. Mazel<sup>1</sup>, C. Loot<sup>1</sup>

<sup>1</sup>*Bacterial Genome Plasticity Unit, Institut Pasteur, Paris, France*

**Background**

The integron is a bacterial recombination system for capturing and rearranging gene cassettes through site-specific recombination, which plays a role in the rise of antibiotic multiresistance in Gram-negative bacteria. The distinctive property of integron recombination sites flanking the cassettes (*attC*) is that they have almost no sequence conservation. Instead, their single-stranded DNA possesses conserved structural features, and *attC* sites are recombined as a folded form of the bottom DNA strand. Contrary to the bottom strand, the recombination of the top strand would integrate the cassette in the opposite orientation, preventing the expression of its gene from the promoter provided by the integron platform.

**Objectives**

## The integron

## Schematic representation of an attC site

In order to understand the basis of this specificity, we tested the recombination of several *attC* sites, and selected 3 of them for further analysis.

## Methods

For these sites, we mutated their structural features and quantified the changes in frequency and orientation of cassette integration for the corresponding bottom and top strands.

## **Conclusions**

We observed that some of the structural features, such as the extrahelical bases (EHBs), play similar roles for all of the tested sites, but the extent to which they influence the frequency and the orientation of cassette integration differs among *attC* sites. Yet other structural features, such as the unpaired central spacer (UCS), have very different, sometimes even opposing effects depending on the *attC* site. Our study suggests that the structural requirements for *attC* site recognition are rather relaxed, and that the control of cassette integration might be governed by more complex mechanisms than previously assumed.

<sup>6</sup>Laboratory of prokaryotic small RNA,  
Max Planck Institute of Terrestrial Microbiology, Marburg, Germany

### **Background**

A consortium of microorganisms adapted to grow in acidic environments participate in the bioleaching of minerals. The facultative aerobic bacterium *Acidithiobacillus ferrooxidans* is a Gram negative, chemolithotrophic, autotroph that utilizes either Fe<sup>2+</sup> or sulfur reduced compounds as electron donors.

### **Objectives**

We are interested in the role of non-coding RNAs (sRNAs and tRNAs) and RNases encoded in a mobile genetic element in translation control.

### **Methods**

By means of bioinformatic analyses 37 genes encoding tRNAs were detected in the mobile element ICEAfe1 from *A. ferrooxidans* strain ATCC 23270. Encoded tRNAs are aminoacylated *in vivo* in *A. ferrooxidans*, although they are transcribed at low levels.

Two strategies were used for their identification of sRNAs: 1. Bioinformatic prediction of transcription units in intergenic regions (IGR) of *A. ferrooxidans* genome and comparison to RNA deep sequencing data. 2. The identification of sRNAs that bind to the RNA chaperone Hfq were identified by RNA deep sequencing. Currently we are working in the validation of target mRNAs of the identified sRNAs. At least two sRNAs encoded in the ICEAfe1 were validated.

Four type II toxin-antitoxins systems specific for strain ATCC 23270 were identified in the ICEAfe1. All four toxins encoded an RNase that is counteracted by the

antitoxin

### **Conclusions**

Different genes encoding possible factors that modulate translation have been identified in the integrative conjugative element ICE *Afe1* from *Acidithiobacillus ferrooxidans*. Whether these systems effectively modulate translation in this organisms is currently under investigation.

## **A NEW SHUTTLE-EXPRESSION SYSTEM TO GENERATE POLYHISTIDINE-TAGGED FUSION PROTEINS IN STAPHYLOCOCCUS AUREUS AND ESCHERICHIA COLI**

S. Schwendener<sup>1</sup>, V. Perreten<sup>1</sup>

<sup>1</sup>University of Bern, Institute of Veterinary Bacteriology, Bern, Switzerland

### **Background**

A better understanding of the metabolism of *S. aureus* is needed. However, only few tools are available for production of tagged fusion proteins.

### **Objectives**

To develop *S. aureus*-*E. coli* shuttle vectors for the expression of target genes and *rgs-his<sub>6</sub>* codon fusions.

### **Methods**

The strong constitutive promoter of *S. aureus* type 1 capsule biosynthetic gene 1A (*P<sub>cap</sub>*) upstream of a multiple cloning site (MCS) and codons for *rgs-his<sub>6</sub>* were synthesized and inserted into pBUS1 background. The MCS contained a BclI site to generate C-terminal RGS-His<sub>6</sub> translational fusions of cloned genes through a simple cut-religation method. Using PCR-based techniques, two vectors were constructed that contain the *P<sub>cap</sub>*-MCS-*rgs-his<sub>6</sub>* sequence (pBUS1-*P<sub>cap</sub>*-HC and pTSSCm-*P<sub>cap</sub>*) and two promoter-less variants suitable for cloning genes including their own promoter (pBUS1-HC and pTSSCm). The plasmids contained the *E. coli* origin ColE1, the terminator sequence *rrnB*(T1)<sub>5</sub> and the tetracycline resistance marker *tet*(L) for *S. aureus* and *E. coli*. Gram-positive replicon was improved through either complementation of the minimum pAMα1 replicon from pBUS1 with the single strand origin *oriL* from pUB110 or substitution with a pT181-family replicon. Plasmid stability, copy numbers and recombinant protein synthesis was analyzed in *S. aureus* and *E. coli*.

### **Conclusions**

The new shuttle vectors displayed increased copy numbers and segregational stability in *S. aureus*. Feasibility of *rgs-his<sub>6</sub>* codon-fusion, gene expression and protein purification were demonstrated in *S. aureus* and *E. coli* using the macrolide, lincosamide, streptogramin B resistance gene *erm*(44). The new His-tag expression

system represents a helpful tool for the direct analysis of target gene function in staphylococci.

## THE PRESENCE OF TEMPERATE BACTERIOPHAGES IN UROPATHOGENIC ESCHERICHIA COLI STRAINS

M. Rumpret<sup>1</sup>, D. Žgur-Bertok<sup>1</sup>, M. Starcic Erjavec<sup>1</sup>

<sup>1</sup>Department of Biology, University of Ljubljana - Biotechnical Faculty, Ljubljana, Slovenia

### Background

Horizontal gene transfer vectors, including bacteriophages, promote the spread of a broad spectrum of genes, among them some encoding medically relevant traits such as virulence factors. In *Escherichia coli* (*E. coli*), temperate bacteriophages have been shown to promote the spread of shiga toxin genes across shigatoxigenic strains of the species<sup>1</sup>.

### Objectives

Here we aim to assess the presence of lysogenic bacteriophages in uropathogenic *E. coli* (UPEC) strains, and to investigate a possible correlation with the virulence factor profiles of the examined strains.

### Methods

Twenty UPEC strains were screened for the presence of 15 different virulence-associated traits (*fimH*, *papC*, *papGII*, *sfaDE\_focIC*, *afaBC\_draBC*, *hlyA*, *cnf1*, *usp*, *ibeA*, *iucD*, *iroCD*, *iroN*, *fyuA* and *ireA*) by PCR amplification of target genes, and were subsequently assigned virulence scores by counting possession of these genes. Additionally, strains were screened for the presence of lysogenic bacteriophages by induction with UV light. Data were analysed using Student's *t*-test.

### Conclusions

We have found that out of the 20 screened strains, nine possessed UV-inducible lysogenic bacteriophages. Furthermore, data analysis has shown that the strains harbouring UV-inducible lysogenic bacteriophages also possessed a significantly higher virulence score than the strains lacking UV-inducible bacteriophages ( $p < 0.01$ ). The results of this preliminary study imply that temperate bacteriophages might have a potential role in virulence factor transfer across UPEC strains.

**THE IMPACT OF Tn3-FAMILY TRANSPOSONS ON DIVERSITY AND EVOLUTION OF BACTERIAL MOBILE GENETIC ELEMENTS**

M. Szuplewska<sup>1</sup>, D. Bartosik<sup>1</sup>

<sup>1</sup>*Department of Bacterial Genetics, University of Warsaw Faculty of Biology, Warsaw, Poland*

**Background**

Transposable elements (TEs) are components of nearly all bacterial genomes. They promote structural changes in DNA, which may result in different phenotypes. We focused on the elements of the Tn3 family – the most abundant group of bacterial transposons.

**Objectives**

Our studies shed a new light on Tn3 family, which is much more diverse than previously thought. We showed that Tn3 elements comprise (i) a composite transposon generated by two copies of a non-composite cryptic transposon, as well as (ii) simple non-autonomous elements (TIMes - Tn3-derived inverted-repeat miniature elements) and (iii) their derivatives. We have provided for the first time evidence **that some of the non-autonomous transposons may contain, in their core regions, functional plasmid replication and stabilizations systems, which can be transferred among replicons co-residing in a bacterial cell.** The transposition events may therefore significantly influence structures of bacterial plasmids leading to generation of molecules exhibiting novel properties. Bioinformatic analyses of the nucleotide sequences of several bacterial genomes revealed the presence of large elements originating from the Tn3-family non-composite transposons, which acquired additional genetic information, thus forming a kind of transposable genomic islands.

**Methods**

Standard methods of molecular biology were used.

**Conclusions**

The obtained results indicate the powerful role of the Tn3-family TEs in the mobilization to transposition of segments of genomic DNA. Such shuffling of genetic information, may significantly influence the structures of bacterial genomes. Huge diversity of the identified elements allows to draw conclusions concerning the high dynamics of evolution of this group of TEs.

## **CULTURE-INDEPENDENT RECOVERY OF IS1216 COMPOSITE TRANSPOSONS FROM ORAL METAGENOMIC DNA.**

S. Tansirichaiya<sup>1</sup>, P. Mullany<sup>1</sup>, A. Roberts<sup>1</sup>

<sup>1</sup>*Microbial Disease, UCL Eastman Dental Institute, London, United Kingdom*

### **Background**

A composite transposon is a transposon consisting of two insertion sequences (ISs) flanking a DNA segment which often carries antibiotic resistance (AR) genes. If both IS elements are the same then it is possible that one copy of the IS element plus the intervening DNA segment can excise as a circular form. This circular molecule has been called an "Unconventional Circularizable Structure" (UCS) or "Translocatable Unit" (TU). IS 1216 composite transposons have been shown to carry various AR genes. In addition UCSs have also been found containing IS 1216.

### **Objectives**

To screen for IS 1216 composite transposons and IS 1216 containing UCSs in human oral metagenomic DNA.

### **Methods**

PCR primers were designed to amplify in the outward direction from IS 1216. The IS 1216 PCR products were then cloned and analysed.

As our PCR strategy would also detect UCSs, PCR primers were designed to amplify outward from the intervening DNA region to determine if each IS 1216 amplicon was derived from a UCS circular structure.

### **Conclusions**

We found four different IS 1216 composite transposons and confirmed the presence of two novel UCSs in the oral metagenomic DNA. One of them contains an antiseptic resistance gene and one contains a universal stress response protein encoding gene.

This is the first report of a PCR strategy to amplify the DNA segment on the composite transposons in metagenomic DNA, and is also the first time that UCSs have been found in metagenomic DNA. This PCR strategy can be used to identify

novel AR genes associated with mobile genetic elements in metagenomes from any environment.

## **DETECTION AND CHARACTERISATION OF INTEGRON GENE CASSETTES IN HUMAN ORAL METAGENOMIC DNA.**

S. Tansirichaiya<sup>1</sup>, M.A. Rahman<sup>1</sup>, A. Antepowicz<sup>1</sup>, P. Mullany<sup>1</sup>, A. Roberts<sup>1</sup>

<sup>1</sup>*Microbial Disease, UCL Eastman Dental Institute, London, United Kingdom*

### **Background**

An integron is a genetic element, which is able to capture gene cassettes and direct the expression of open reading frames (ORFs) contained within them. They are involved in the dissemination of antibiotic resistance genes (ARGs) in many pathogens. The oral cavity is a reservoir of ARGs; however, these have not been shown previously to be present on an integron cassette.

### **Objectives**

To investigate the presence of integrons and associated gene cassettes in the human oral cavity by using a PCR-based approach.

### **Methods**

Different primer sets were tested on oral metagenomic DNA obtained from both the UK and Bangladesh, including novel primers based on the *Treponema denticola* integrase and *attC* sequences, and previously published primers targeting various conserved regions on different integrons. The resulting metagenomic amplicon libraries were then sequenced and analysed.

### **Conclusions**

A diverse array of ORFs presents on gene cassettes and associated with integron integrases have been identified. The cassettes contain ORFs predicted to confer antibiotic resistance and adaption to environmental stresses including a putative chloramphenicol acetyltransferase, bleomycin binding protein, multidrug transporter, cof-like hydrolase, competence and motility related proteins.

This is the first study confirming the presence of integron gene cassettes in oral metagenomic DNA. The predicted proteins are likely to carry out a multitude of functions however the function of the majority is as yet unknown. We hypothesise that the oral cavity may be a rich source of diverse integron cassettes because it is such a variable physicochemical and stressful environment for its bacterial inhabitants.

#### **HUH TRANSPOSASES AND GENOME DYNAMICS**

B. Ton-Hoang<sup>1</sup>, M. Chandler<sup>1</sup>, S. He<sup>2</sup>, A. Sarcos<sup>1</sup>, A. Corneloup<sup>1</sup>, L. Lavatine<sup>1</sup>,  
B. Marty<sup>1</sup>, C. Guynet<sup>1</sup>, P. Siguier<sup>1</sup>, G. Fichant<sup>1</sup>, Y. Quentin<sup>1</sup>, F. Dyda<sup>2</sup>

<sup>1</sup>CNRS, Laboratoire de Microbiologie et Génétique Moléculaire, Toulouse, France

<sup>2</sup>Laboratory of Molecular Biology, NIH, Bethesda MD 20892-0560, USA

#### **Background**

We address the central role of a functionally related group of transposable elements called “HuH elements” in structuring and shaping bacterial genomes. We have identified and characterised a widespread class of IS (IS200/IS605 family) fundamentally different from classical TEs: they use obligatory single strand DNA intermediates and have ends with subterminal imperfect palindromes (IP) which are recognised and bound by their transposases. These transposases are members of a larger “HuH” endonuclease superfamily. The protein binds the subterminal IP located some distance from the cleavage sites. Remarkably, cleavage sites are not recognised directly by the protein but by short “guide” sequences 5' to the IP foot. Recognition involves a network of canonical and non-canonical base interactions similar to those found in RNA structures.

#### **Objectives**

We have demonstrated the importance of the lagging strand template for activity of some members and our *in silico* genomic analysis suggests that all IS200/IS605 family members have evolved a mode of transposition that exploits ssDNA at the replication fork.

#### **Methods**

Some members of this group appear to have been domesticated to perform important roles in the prokaryotic cell: such as homing endonucleases in some group I prokaryotic introns and as enzymes responsible for proliferation of short intergenic multicopy palindromic regulatory sequences called REPs.

#### **Conclusions**

The results provide an overview of the role of “HuH” transposases and their associated mobile elements in shaping the prokaryotic genome.

**FUNCTIONAL CHARACTERIZATION OF AN INOSITOL METABOLISM  
ENCODING GENE CLUSTER CONTAINED IN ICEEFM1 OF ENTEROCOCCUS  
FAECIUM**

J. Top<sup>1</sup>, A. Bisschop<sup>1</sup>, M.M.A. Sleur<sup>1</sup>, M.J.M. Bonten<sup>1</sup>, R.J.L. Willems<sup>1</sup>

<sup>1</sup>Medical microbiology, University Medical Center Utrecht, Utrecht, Netherlands

**Background**

Whole genome sequencing revealed the presence of an integrative conjugative element, *ICEEfm1* in a clinical *Enterococcus faecium* (Efm) isolate (E1504) with an insertion of a cluster of 10 genes putatively involved in inositol metabolism.

**Objectives**

Functional characterization of the inositol metabolism (*iol*) gene cluster.

**Methods**

A cre-lox recombination system was used to construct a markerless *iolD* deletion mutant in strain E1504. The phenotype was determined by growth on minimal medium with inositol as carbon source (M-ino). The genetic organization of the gene cluster was determined by operon and promoter mapping and expression was determined after growth in rich and minimal medium in the presence and absence of myo-inositol. An *in vivo* mouse gut-colonization model was used to compare colonization abilities of E1504-wildtype and *iolD* mutant.

**Results.** The *iolD* deletion resulted in abolished growth in M-ino. The gene cluster is organized as an operon of 10 genes with its own promoter. Expression was only observed in the presence of myo-inositol and absence of other carbon sources. No difference was observed in gut-colonization abilities between wild-type and mutant.

**Conclusions**

The 10 gene insertion in *ICEfm1* confers Efm the ability to grow when only inositol is available as carbon source. Due to the availability of additional other sugars the *iol* gene cluster did not provide a selective advantage in the *in vivo* mouse model. Possibly the gene cluster was acquired in an environment where carbon sources were limited and only inositol was present like e.g. plants and soil.

## **GENETIC AND LIFE-HISTORY TRAITS DETERMINING LYSOGENY AND THE DISTRIBUTION OF PROPHAGES**

M. Touchon<sup>1</sup>, A.U.D.E. Bernheim<sup>1</sup>, E. Rocha<sup>1</sup>

<sup>1</sup>*Genomes and Genetics, Institut Pasteur, PARIS Cedex 15, France*

### **Background**

Bacterial viruses (phages) are ubiquitous and have a strong impact on microbial population dynamics. Temperate phages may become prophages upon cell infection, producing lysogenic hosts and thus contributing to the evolution of bacterial gene repertoires.

### **Objectives**

We identified and studied 2246 prophages among the genomes of 1196 bacterial species to pinpoint the genetic and life-history traits associated with lysogeny and how they shape the distribution of prophages among bacteria.

### **Methods**

Surprisingly, whereas lysogens have larger genomes and are more often pathogens, they are not different in terms of cell volume or defense systems, like CRISPR-Cas. Importantly, growth-related trade-offs seem to be key to the decision of lysogeny. We propose that lysogeny is more adaptive when hosts show large variations in the resources they can provide. Accordingly, bacteria with low minimal doubling times, which are associated with strong variations in growth rates and cell volume, show remarkably high rates of lysogeny. This fits theory suggesting that lysogeny is a strategy of slow vertical reproduction in waiting for future more efficient horizontal reproduction. This strategy has important consequences for bacterial evolution: we find that lysogens have much more diverse gene repertoires, after controlling for other factors, showing the key role of lysogeny in bacterial adaptation.

### **Conclusions**

Our work shows a complex dependency of bacterial genetic diversification on host-parasite interactions and the life-history traits of both bacteria and phage. It allows establishing coarse-grained predictions of the abundance and distribution of prophages and explains the paucity of prophages in certain bacterial clades.

**CONTRIBUTION OF INSERTION SEQUENCE ELEMENTS TO THE GENOME PLASTICITY OF CUPRIAVIDUS METALLIDURANS AE126**

J. Vandecraen<sup>1</sup>, P. Monsieurs<sup>1</sup>, N. Leys<sup>1</sup>, M. Mergeay<sup>2</sup>, R. Van Houdt<sup>1</sup>, A. Aertsen<sup>2</sup>

<sup>1</sup>Unit of Microbiology, SCK•CEN, Mol, Belgium

<sup>2</sup>Microbial and Molecular Systems, KU Leuven, Leuven, Belgium

**Background**

Mobile genetic elements play a significant role in bacterial evolution. Insertion Sequence (IS) elements are of specific interest as they constitute an importing driving force for genome plasticity. *Cupriavidus metallidurans* AE126 (type strain CH34 cured of pMOL30) harbors 19 distinct IS elements from nine IS families, reaching a total of 52 intact IS copies. *C. metallidurans* AE126 displays in the presence of toxic zinc concentrations spontaneous mutations resulting in an increased zinc resistance.

**Objectives**

The objective of this study is: (i) to determine the contribution of IS elements to genome adaptation of AE126 after zinc stress and (ii) to examine the putative stress-specific inducible transposition of IS elements.

**Methods**

Zinc resistant AE126 derivatives were screened by PCR and mutations were identified by sequencing. Promoter transcription of IS elements was analyzed with the promoter probe vector pGLR1.

**Conclusions**

All derivatives had a base substitution/indel (45%) or an insertion of an IS element (55%) in the regulatory locus of *cnr* (cobalt-nickel resistance). Seven IS elements were identified to be transposed into the regulatory locus of *cnr*. Three elements were found more often with respect to their copy number and transcription of their promoters were induced by supplementing zinc or cadmium to the growth medium but not nickel or cobalt. Some AE126 derivatives, e.g. with an *ISRme5* element inserted in the same orientation as *cnrYXH*, are pre-adapted as they evolved to ameliorate resistance to other stress challenges. Pre-adaptation could putatively be explained by the increased transcription of the mutated *cnr*-operon and concomitant co-transcription of *ISRme5*.

**DISTRIBUTION AND VARIANT CHARACTERISTICS OF VSP-I ISLAND IN VIBRIO CHOLERAЕ**

D. Wang<sup>1</sup>

<sup>1</sup>*Dept. of Diarrhoeal Diseases,*

*National Institute for Communicable Disease Control & Prevention China CDC,  
Beijing, China*

Objective To investigate the distribution and characteristics of vibrio seventh pandemic island-I (VSP-I) in *Vibrio cholerae*. Method All *V. cholerae* genome sequences in GenBank were downloaded and screened for VSP-I island using VSP-I (VC0175~VC0185) of strain N16961 as the reference sequence. MUMmer software was used to analyze single nucleotide polymorphism (SNP); OrthMCL software was used for homologous gene analysis; finally the BLAST software was used to search sequence variation and functional annotation. Conclusions VSP-I widely exists in the genomes of all the seventh epidemic *V. cholerae* O1 strains and its sequence is highly conserved; Among the 105 *V. cholerae* O1 strains, the VSP-1 sequences of 94 strains were completely identical, the VSP-I sequences of 11 strains had 1~14 SNP loci, respectively. The VSP-I exists also in the genomes of two non-O1/O139 strains. However, their VSP-I sequences contain some insertion and deletion (INDEL) comparing to that of O1 strains. VSP-I had 9 conserved genes totally. Among them, VC0183 existed in all strains, but its length of the non-O1/O139 strains was different to the O1 strains. Five (VC0181~VC0185) of 9 genes were involved in its transfer and integration. And VC0178 encoding potato glycoprotein analogues and VC0180 encoding protein hydrolase may be related to virulence. As a specific genetic cluster within the seventh cholera pandemic strains, VSP-I has been transferred to the non-O1/O139 strains, and variation of its sequence has been occurred as well.

**DAMAGES CAUSED BY SILVER NANOPARTICLES AND SILVER NITRATE ON PSEUDOMONAS AERUGINOSA AND STAPHYLOCOCCUS AUREUS**

N.J. Andrade<sup>1</sup>, P.E. Fernandes<sup>1</sup>, M.P. Silveira<sup>1</sup>, D.S. Costa<sup>1</sup>, J.P.N. Sá<sup>1</sup>,  
H.C. Mantovan<sup>2</sup>

<sup>1</sup>Tecnologia de Alimentos, Universidade Federal de Viçosa - UFV, Viçosa, Brazil

<sup>2</sup>Microbiologia, Universidade Federal de Viçosa - UFV, Viçosa, Brazil

**Background**

The antimicrobial activity of silver is well documented, however its mechanism of action is not well understood. It is unclear whether the effects of silver nanoparticles (Ag-NPs) and Ag<sup>+</sup> ions are similar or have different antimicrobial mechanisms.

**Objectives**

The objective was to compare the damages caused by Ag-NPs and silver nitrate (AgNO<sub>3</sub>) on gram-positive and gram-negative bacteria by transmission electron microscopy.

**Methods**

Ag-NPs were synthesized by reduction of AgNO<sub>3</sub> with sodium citrate. *Pseudomonas aeruginosa* ATCC 15442 and *Staphylococcus aureus* ATCC 6538 were treated with Ag-NPs or AgNO<sub>3</sub> at 37 °C for 2 h. The cells were fixed with 2.5% glutaraldehyde for 24 h and post-fixed in 1% osmium tetroxide for 2 h at 25 °C, washed once in 0.1 M PBS and dehydrated by sequential transfer in a graded series of ethanol solutions. Fine sections were cut with diamond blades using ultramicrotome and double stained with uranyl acetate and lead citrate saturated and observed using the transmission electron microscope with EDX detector (FEI Tecnai-G2-20, 2006) available in microscopy center of Federal University of Minas Gerais.

**Conclusions**

The Ag-NPs affected severely *P. aeruginosa*, forming a condensation region in the center of the cell and a clear zone around. According to the EDX spectrum, the condensation region is composed mainly of silver, sulfur and phosphorus. However, these elements were not detected in the clear area. Damages to *S. aureus* were similar to those caused on *P. aeruginosa*, however, milder form. Damages caused by AgNO<sub>3</sub> were similar to those caused by Ag-NPs.

**New antimicrobial mechanisms**

**LIPID PEROXIDATION IS NOT RELATED TO THE ANTIMICROBIAL MECHANISM OF SILVER NANOPARTICLES AGAINST PSEUDOMONAS AERUGINOSA AND STAPHYLOCOCCUS AUREUS**

R. Barbosa Teodoro Alves<sup>1</sup>, P.E. Fernandes<sup>1</sup>, D.S. Costa<sup>1</sup>, P.C. Bernardes<sup>2</sup>, N.J. Andrade<sup>1</sup>

<sup>1</sup>Department of Food Technology, Federal University of Viçosa, Viçosa, Brazil

<sup>2</sup>Department of Food Engineering, Federal University of Espírito Santo, Alegre, Brazil

**Background**

The antimicrobial activity of silver nanoparticles (Ag-NPs) may be related to the formation of reactive oxygen species (ROS). A common feature among the different ROS is the ability to cause some oxidative damage in cells. The lipids are the main targets during oxidative stress.

**Objectives**

The objective was to determine whether the Ag-NPs cause oxidative stress in the lipids of membranes of *Pseudomonas aeruginosa* or *Staphylococcus aureus*.

**Methods**

The Ag-NPs were synthesized according Monteiro et al. (2009), with some modifications. The lipid peroxidation analysis was performed according to Becerra et al. (2006), with some adjustments. Samples containing 50 µg/ml Ag-NPs or AgNO<sub>3</sub> were inoculated with 1.0 x 10<sup>8</sup> CFU/ml of *P. aeruginosa* or *S. aureus* and incubated at 37°C for 1 h. Then was added 1 ml of 35% trichloroacetic acid (w/v). After 20 min, the samples were treated with 1 ml of 0.5% thiobarbituric acid (w/v) and heated at 80°C for 30 min, then cooled and centrifuged. The absorbance was determined at 535 nm. The controls with water and 2,2'-azobios (2-methyl-propionamide) dihydrochloride (AAPH) were made. A standard curve of malondialdehyde was obtained by hydrolysis of 1'1'3'3'-tetraetoxipropano.

**Conclusions**

The concentration of malonaldehyde, a product of lipid peroxidation, in *P. aeruginosa* and *S. aureus* cells treated with Ag-NPs and AgNO<sub>3</sub> was not different ( $p > 0.05$ ) from cells treated with water, however, was lower from the cells treated with AAPH, a ROS generator. This indicates that lipid peroxidation is not involved in the antimicrobial activity of Ag-NPC and AgNO<sub>3</sub>.

#### **ASSESSMENT OF E. COLI BIOFILM GROWTH ON DIFFERENTLY TERMINATED DIAMOND THIN FILMS**

*B. Jurková<sup>1</sup>, H. Kozák<sup>2</sup>, A. Artemenko<sup>2</sup>, O. Babchenko<sup>2</sup>, P. Matyska-Lišková<sup>1</sup>, J. Beranová<sup>1</sup>, I. Konopásek<sup>1</sup>, A. Kromka<sup>2</sup>*

<sup>1</sup>Dpt. of Genetics and Microbiology,

*Charles University in Prague - Faculty of Science, Prague 2, Czech Republic*

<sup>2</sup>Dpt. of Optical Materials,

*The Academy of Sciences of the Czech Republic - Institute of Physics, Prague 6, Czech Republic*

#### **Background**

Diamond is a material with interesting properties, such as chemical inertness, hardness, high transparency and good biocompatibility with eukaryotic cells. These qualities make this material very promising for various bio-medical applications such as biosensors, articular implant coatings, tissue-engineering and regenerative medicine. Several published works also indicate that diamond thin films, due to their tailored surface properties, could possess anti-adhesive or even antimicrobial properties.

#### **Objectives**

The objectives of our work is to develop and standardize the methods for diamond thin film deposition on glass substrate, to develop and optimize the methods for testing of antibacterial properties of diamond surfaces, to assess these properties and to compare the influence of diamond surface terminations on their possible antibacterial character.

#### **Methods**

We used diamond films CVD deposited by microwave plasma CVD process. *Escherichia coli* was chosen as the model bacterium. Bacterial biofilm was cultivated on diamond-coated glass in CDC biofilm reactor. Fluorescence microscopy and ATP assay was used to quantify bacterial growth on diamond surfaces.

#### **Conclusions**

We managed to deposit diamond thin films of standard properties on glass over large areas (1x3"). We successfully developed the continuous cultivation method for biofilm growth and testing of antibacterial properties of diamond thin films under different conditions. We compared the antibacterial potential of diamond films with different surface terminations (H, O and F).

**SUSCEPTIBILITY OF FOOD CONTAMINATING MICROBIAL COMMUNITIES TO ATMOSPHERIC COLD PLASMA AND IMPLICATIONS FOR RESISTANCE-PROOF ANTI-MICROBIAL TREATMENT**

D. Boehm<sup>1</sup>, L. Han<sup>1</sup>, C. Heslin<sup>1</sup>, A. Patange<sup>1</sup>, D. Ziuzina<sup>1</sup>, P.J. Cullen<sup>1</sup>, P. Bourke<sup>1</sup>

<sup>1</sup>Food Science and Environmental Health, Dublin Institute of Technology, Dublin, Ireland

**Background**

Atmospheric cold plasma (ACP) has received increasing attention as a novel anti-microbial treatment, which may be less prone to resistances. Containing ions, free electrons, UV light and reactive species, plasma can cause damage to microbial cell walls and/or intra-cellular components.

**Objectives**

To determine the anti-microbial efficacy of ACP on food-contaminating microorganisms and their ability to develop resistance to plasma treatment.

**Methods**

The inactivation of a range of common microbial food contaminants using di-electric barrier discharge ACP was investigated and cultures of *S.aureus* and *E.coli* were subjected to repeated sub-lethal plasma treatment. The background microflora of plasma-treated meat products was analysed over 2-4 week storage and community profiling was performed using PCR-amplification and denaturing gradient gel electrophoresis (DGGE) of 16s RNA.

**Conclusions**

Microorganisms displayed varying susceptibility to ACP, with *C.jejuni* and *B.thermosphacta* showing rapid inactivation whereas *E.coli*, *L.monocytogenes* and *S.aureus* required longer treatment times. Repeated selection of sub-lethally treated colonies did not increase resistance in short-term adaptation studies. The background microflora of meat products was reduced up to 1log over 2-4 week storage following treatment and PCR-DGGE revealed differences in plasma tolerance between microbial populations. In an era of growing anti-microbial resistances, resistance-proof alternative treatments are gaining significance. ACP has shown anti-microbial effects on a variety of microorganisms and acts through a range of physico-chemical effects that may prevent the development of resistances. Such novel anti-microbial strategies have implications not only in the food industry but also the medical sector but will require long-term adaptation studies to ensure resistance-proof.

N. KELLER<sup>2</sup>, P. ANDRE<sup>1</sup>

<sup>1</sup>*Faculté de Pharmacie Laboratoire de Biophotonique et de Pharmacologie,  
UMR CNRS 7213, STRASBOURG Cedex, France*

<sup>2</sup>*Institut de Chimie et Procédés pour l'Energie l'Environnement et la Santé,  
UMR CNRS 7515, STRASBOURG Cedex, France*

#### **Background**

Healthcare textiles are known to be able to transfer pathogens.

#### **Objectives**

To provide new antimicrobial textiles, we functionalized decontaminating photocatalytic textiles by the innovative LBL (Layer-by-Layer) technique. Photocatalysis deals with the activation of TiO<sub>2</sub> semiconductor particles by UVA, which produces highly Reactive Oxygen Species responsible for the microorganisms inactivation.

#### **Methods**

The LBL coating is based on successive application of positively charged layers and negatively charged layers. To improve the adhesion of the first layer on the fibers, the textile was first submitted to a hydrolysis using KOH solution. Negatively-charged TiO<sub>2</sub> particles with a polyethylenimine (PEI) polycation layer were alternatively spraying onto textiles. Another functionalization was also performed by adding an interfacial layer of PEI before building bilayers of alternatively positively-charged TiO<sub>2</sub> particles with a poly(styrene sulfonate) (PSS) polyanion. These sequence were repeated 1-5-10 times until (PEI/TiO<sub>2</sub>)<sub>n</sub> or PEI/(PSS/TiO<sub>2</sub>)<sub>n</sub> bilayers were achieved. The antibacterial properties of functionalized textiles against *E.coli* were determined after 15-30-60min of solar light radiation (226W/m<sup>2</sup> of visible light).

#### **Conclusions**

Whereas no antibacterial effect was observed for the textiles pretreated by KOH and kept in the dark, we respectively obtained a 2log reduction for the textiles functionalized with only one layer of PEI and a 6log reduction with addition of a single layer of TiO<sub>2</sub> (PEI/TiO<sub>2</sub>)<sub>1</sub>. For the PEI/(PSS/TiO<sub>2</sub>)<sub>n</sub> textiles, antibacterial activity is function to solar light duration and also depends of the number of bilayers. The best antibacterial activity (4log reductions) was obtained for PEI/(PSS/TiO<sub>2</sub>)<sub>10</sub> under 60min of solar light radiation.

#### **DETERMINING GROWTH INHIBITION MECHANISMS OF THE ANTIMICROBIAL AGENT FREE NITROUS ACID (FNA) FROM THE TRANSCRIPTOME RESPONSE OF PSEUDOMONAS AERUGINOSA PAO1**

S. Gao<sup>1</sup>, L. Fan<sup>1</sup>, L. Peng<sup>1</sup>, Z. Yuan<sup>1</sup>, P. Bond<sup>1</sup>

<sup>1</sup>The University of Queensland, Advanced Water Management Center, Brisbane, Australia

### **Background**

Free nitrous acid (FNA) has recently been demonstrated as an antimicrobial agent to a range of microorganisms. However, the antimicrobial mechanism of FNA is largely unknown.

### **Objectives**

Consequently, we aim to gain a systematic understanding of the bacteriostatic/bactericidal effects of FNA. This was examined on *Pseudomonas aeruginosa* PAO1, an organism with intrinsic resistance to various antibiotics and disinfectants.

### **Methods**

*P. aeruginosa* was grown under anaerobic denitrifying conditions and when FNA was added (0.05 mg N/L) growth temporarily stopped. From cultures either exposed or not exposed to added FNA, RNA was extracted and transcripts were detected by HiSeq-Illumina sequencing. Transcripts were quantified and those exhibiting  $\geq 2.5$  or  $\leq 2.5$  fold abundance change were designated as differentially expressed in response to FNA.

### **Conclusions**

In response to FNA 177 genes showed increased transcription while 471 genes exhibited decreased transcript levels. Genes coding ribosome proteins showed significantly decreased transcript levels, implicating that protein biosynthesis was severely inhibited by FNA. Respiration was likely inhibited, as lowered substrate utilization coincided with decreased transcript levels of genes coding for denitrification. In contrast, genes encoding nitric oxide reductase were up regulated, which possibly functioned to remove toxic NO derived from the added nitrite. In the response, genes of the tricarboxylic acid cycle were less expressed, while enzymes of the glyoxylate shunt had increased levels. Evidently the cells would generate less reducing power through these cycles. This first investigation elucidating the

mechanisms of FNA effect on *P. aeruginosa*, contributes underpinning knowledge for potential application of this novel antimicrobial agent.

**New antimicrobial mechanisms**

## **ELUCIDATION OF THE MODE OF ACTION OF A NEW ANTI-PSEUDOMONAL COMPOUND**

E. Gerits<sup>1</sup>, A. Fierro Gutiérrez<sup>1</sup>, M. Fauvart<sup>1</sup>, N. Verstraeten<sup>1</sup>, J. Michiels<sup>1</sup>

<sup>1</sup>Department of Microbial and Molecular Systems, KU Leuven, Heverlee, Belgium

### **Background**

*Pseudomonas aeruginosa* is a gram-negative pathogen that causes severe infections in immunocompromised patients and is responsible for 10 – 15% of the hospital-acquired infections worldwide. Due to the emergence of multidrug-resistant *P. aeruginosa* strains, there is an urgent need for the development of new antibiotics with activity against *P. aeruginosa*. We recently identified a new antibacterial compound, SPI003, which inhibits growth of various gram-positive and gram-negative pathogens, including *P. aeruginosa*.

### **Objectives**

In this study, we sought to unravel the mode of action of SPI003, using *P. aeruginosa* as a model organism.

### **Methods**

In order to unravel the mode of action of SPI003, different approaches were used. First, a library of *P. aeruginosa* mutants was screened to identify mutants that are sensitive or resistant to SPI003. Second, spontaneous resistant mutants were generated by plating *P. aeruginosa* cells on agar plates supplemented with SPI003 at a final concentration of 5 x MIC. Third, a transcriptome analysis was carried out on exponentially-growing cells of *P. aeruginosa* treated with the compound. Finally, the membrane permeability of *P. aeruginosa* was examined after exposure to SPI003 using established assays.

### **Conclusions**

Our study shows that SPI003 exhibits a fast membrane-damaging activity, which is likely to be the primary cause of its antibacterial activity.

**New antimicrobial mechanisms**

## **INVESTIGATION OF ATMOSPHERIC COLD PLASMA AGAINST ESCHERICHIA COLI MUTANTS**

L. Han<sup>1</sup>, D. Boehm<sup>1</sup>, P.J. Cullen<sup>2</sup>, P. Bourke<sup>1</sup>

<sup>1</sup>*Food Science and Environmental Health, Dublin Institute of Technology, Dublin, Ireland*

<sup>2</sup>*School of Chemical Engineering, University of New South Wales, Sydney, Australia*

### **Background**

Atmospheric cold plasma (ACP) is effective against a wide range of pathogenic microorganisms with promising application in food and medical industry. Generation of reactive oxygen species (ROS) plays a crucial role when air/oxygen containing gases are used. As a mixed group of oxidative reactive species generated by ACP, there are limited publications about the cellular regulation system under plasma pressure.

### **Objectives**

To investigate the effect of the plasma stress on the microbial inactivation, intracellular reactive oxygen species and genetic regulation.

### **Methods**

*Escherichia coli* BW 25113 and its isogenic mutants in *soxR*, *soxS*, *oxyR*, *rpoS* and *dnaK* genes were suspended in phosphate buffered saline (PBS) at  $10^8$  CFU/ml. Samples were then treated with high voltage plasma (80 kV<sub>RMS</sub>) in a sealed package for 1, 3 and 5 min following 0, 1 and 24 h post-treatment storage. Intracellular ROS were measured using fluorescence spectrophotometer (Biotek synergy, 480/530nm) with the probe 2', 7'- dichlorofluorescein diacetate immediately after storage.

### **Conclusions**

Without post-treatment storage time, the absence of RpoS and OxyR led to higher reduction after treatment. However, DnaK showed its repairing function correlated to cell survival with 24 h, while it has no effect on reducing intracellular ROS level. SoxS became important with both 1 and 24 h storage, which is not observed in SoxR. It implied their different characteristics as subunits. Overall, the cell response against plasma generated oxidative stress could be divided to short term and long term, which are dominated by oxidative stress deletion genes and damage repairing genes.

**New antimicrobial mechanisms**

## **NEW ENVIRONMENTAL-FRIENDLY COMPOUNDS TO COMBAT CITRUS CANKER**

M.M. Kopacz<sup>1</sup>, A. Glock Lorenzoni<sup>1</sup>, E. Krol<sup>1</sup>, A. de Sousa Borges<sup>1</sup>, I. da Silva<sup>2</sup>,  
C.R. Polaquini<sup>3</sup>, L.O. Regasini<sup>3</sup>, H. Ferreira<sup>2</sup>, D.J. Scheffers<sup>1</sup>

<sup>1</sup>Molecular Microbiology, GBB, Groningen, Netherlands

<sup>2</sup>Departamento de Bioquímica e Microbiologia, Instituto de Biociências, Rio Claro,  
Brazil

<sup>3</sup>Departamento de Química e Ciências Ambientais,  
Instituto de Biociências Letras e Ciências Exatas, Rio Claro, Brazil

### **Background**

The culture of citrus fruits is constantly under the threat of plant diseases. One of them is citrus canker, which is caused by the bacterial plant pathogen *Xanthomonas citri* subsp. *citri* (Xac). Current modes of prevention of Xac infection and spreading include spraying trees with copper containing bactericides and eradication of infected and healthy trees in a certain radius around. Despite these efforts, about 300 Million tons of fruit per year were lost during the last decade.

### **Objectives**

In addition to being inefficient, copper containing bactericides negatively impact soil quality since copper accumulates in the environment. Therefore, more sustainable ways to combat citrus canker are urgently needed. Recently, a class of plant-derived semi-synthetic compounds, the alkyl gallates, has shown promising activity against Xac [1] and the bacterial cell division protein FtsZ has been found to be their target (unpublished).

### **Methods**

Here, we present *in vitro* results on the activity of the alkyl gallates against FtsZ from different bacteria. We also discuss the ideal alkyl chain length of a lead gallate candidate as a platform for chemical synthesis of new compounds with enhanced antibacterial activity.

### **Conclusions**

Our initial results show that the development of novel environmental-friendly antibacterials to combat Xac is feasible. The efficacy of these compounds in the field will be evaluated and their toxicity to plants and animals will be determined. We expect that the compounds can be used as a sustainable alternative to prevent citrus canker and they will contribute to control the spread of Xac in citrus plants.

**New antimicrobial mechanisms**

## **MECHANISMS OF ANTIBACTERIAL ACTION OF CATIONIC PEPTIDE WARNERIN**

V. Korobov<sup>1</sup>, L. Lemkina<sup>1</sup>, T. Poludova<sup>1</sup>, L. Filatova<sup>1</sup>

<sup>1</sup>*Laboratory of microorganisms' biochemical development,  
Institute of Ecology and Genetics of Microorganisms UB RAS, Perm, Russia*

### **Background**

Rapid development of antibiotic resistance of bacteria necessitates the search for new natural compounds inhibiting the growth and functioning of pathogenic microflora.

### **Objectives**

To study the antibacterial mechanisms of warnerin, a new peptide from lantibiotic family that demonstrate the sequence of events causing the death of attacked bacterial cells.

### **Methods**

Outcomes of warnerin attack of *Staphylococcus epidermidis* 33 GISK (Moscow) were analyzed using the combination of different methods such as polarography (respiration), spectrography (intracellular potassium loss), fluorescence assay of membrane potential dynamics and hydroxyl radicals' formation, electron and atomic-force microscopy of cell structure damages

### **Conclusions**

Peptide introduction into the bacterial incubation medium results in the increase in their oxygen consumption followed by rapid cellular release of potassium ions and sharp decline of intracellular ATP concentration. Apparently, the disturbance of ATP-linked electron transport along the respiratory chain favors their accumulation on iron-sulfur centres. This results in increase of free Fe<sup>2+</sup> ions and as a consequence, to the elevation of hydroxyl radical concentrations. Peptide inhibition of ATP formation is accompanied by marked proton accumulation on the outer side of bacterial membrane, particularly in its adjacent layers of peptidoglycane. This facilitates the autolytic hydrolase extrusion from the binding sites and to uncontrolled total bacteriolysis that is revealed by microscopic data. Results of investigation evidence for the pluripotent antibacterial action of warnerin that point to expressed prospects for its practical use.

**The work was supported by RFBR grant No. 14-04-00687\_a.**

### New antimicrobial mechanisms

#### FUNCTIONALIZATION OF PROTOPORPHYRIN IX WITH ANTIMICROBIAL PEPTIDES TO ENHANCE PHOTOANTIMICROBIAL CHEMOTHERAPY (PACT).

M. Kossakowska-Zwierucho<sup>1</sup>, D. Grzywacz<sup>2</sup>, W. Kamysz<sup>3</sup>, K.P. Bielawski<sup>1</sup>, J. Nakonieczna<sup>1</sup>

<sup>1</sup>Laboratory of Molecular Diagnostics Department of Biotechnology, Intercollegiate Faculty of Biotechnology University of Gdansk and Medical University of Gdansk, Gdansk, Poland

<sup>2</sup>R&D Laboratory, Lipopharm.pl, Zblewo, Poland

<sup>3</sup>Department of Inorganic Chemistry, Faculty of Pharmacy Medical University of Gdansk, Gdansk, Poland

#### Background

Photodynamic antimicrobial chemotherapy (PACT) combines activities of light, photosensitizing compound (PS) and oxygen, to eradicate microorganisms through the oxidation- related mechanisms. To obtain more specific photodynamic action, PS can be functionalized with various types of adducts. Presented approach combines activity of a photosensitizer and antimicrobial peptides (AMPs).

#### Objectives

Protoporphyrin IX (PPIX) covalently conjugated with antimicrobial peptides: PEX or CAM, was analyzed for its spectral properties and antimicrobial action. Bacterial strains used in the study were *Staphylococcus aureus* Newman (MSSA) and COL (MRSA).

#### Methods

Peptides were synthesized using the methodology Fmoc/tBu on polystyrene resin and purified by HPLC. MIC values were determined by the broth dilution method in BHI medium in the darkness. Absorbance spectra screening was performed using the EnVision™ microplate reader (PerkinElmer) within 350-700 nm range. PACT was conducted using the LED lamp (SecureMedia, Poland) emitting incoherent red light ( $\lambda_{\max}$  627 nm). Viability of bacteria was calculated counting colony forming units (CFU).

#### Conclusions

Combination of pure compounds showed no influence on PPIX spectral properties and AMPs activity by means of MIC values and showed synergistic effect of PPIX and CAM in PACT experiments. PS-AMP conjugates reveal weaker antimicrobial activity by means of MIC values, as compared to pure peptides. Conjugation of peptides to PPIX changed its spectral properties, visualized by hypsochromic shift of absorbance spectra, hyperchromic effect in Soret band and hypochromic effect in Q bands. These observation implied weaker/no photodynamic activity induced by red light, which was confirmed experimentally, however indicated efficient activity induced by blue light.

**SILVER NANOPARTICLES INHIBIT MOTILITY, PYOVERDINE PRODUCTION AND BIOFILM FORMATION BY PSEUDOMONAS AERUGINOSA**

K. Markowska<sup>1</sup>, S. Nowotniak<sup>1</sup>, A.M. Grudniak<sup>1</sup>, K.I. Wolska<sup>1</sup>

<sup>1</sup>Department of Bacterial Genetics,

Institute of Microbiology Faculty of Biology University of Warsaw, Warsaw, Poland

**Background**

Antimicrobial efficacy of silver nanoparticles (AgNPs) was proved and broad applications were proposed so far. This study shows the potential mechanism of AgNPs action towards opportunistic pathogen *Pseudomonas aeruginosa*.

**Objectives**

Study of the AgNPs effect on selected *P. aeruginosa* virulence factors.

**Methods**

*P. aeruginosa* PAO1 was used in this study. Silver nanoparticles were obtained from Nano-Tech (Warsaw, Poland). Minimal inhibitory concentration of silver nanoparticles that inhibit biofilm formation (MBIC) was estimated by standard two-fold dilution method. Swimming motility was examined on 0.3% agar plates and swarming motility on 0.6% agar plates supplemented with 0.05–0.5xMBIC AgNPs. Twitching motility across the glass surface was analysed after staining with crystal violet. Pyoverdine production was estimated in 48-hour PAO1 biofilms grown in microtitre plates. Biofilm formation was studied after crystal violet staining and cell survival was determined in Live/Dead Assay (Promega). Statistical analysis of the results in comparison to control sample without AgNPs was performed.

**Conclusions**

Strong antibacterial effect of AgNPs was observed. MBIC was 4 microgram mL<sup>-1</sup>. There was significant decrease from 22% to 40% in swimming and from 22% to 29% in swarming motility in samples containing 0.1–0.5xMBIC of AgNPs in comparison to *P. aeruginosa* PAO1 incubated without nanoparticles. No influence of AgNPs on twitching motility was observed. Pyoverdine production was significantly inhibited by AgNPs in concentration of 0.5 MBIC. The inhibition of biofilm formation by 44% was also observed. **Hence, it was shown that** silver nanoparticles affect several virulence factors of *P. aeruginosa* including swarming, swimming motility, pyoverdine production and biofilm formation.

### **New antimicrobial mechanisms**

#### **ANTIBIOTIC ACTIVITY OF MICROBIAL STRAINS ISOLATED FROM MYTILUS EDULIS, KIEL FJORD, BALTIC SEA**

A. Motie<sup>1</sup>, J. Wiese<sup>2</sup>, J.F. Imhoff<sup>2</sup>, E. Gorokhova<sup>1</sup>

<sup>1</sup>*Applied Environmental Science and Analytical Chemistry, Stockholm University, Stockholm, Sweden*

<sup>2</sup>*Marine Microbiology, GEOMAR Helmholtz Centre for Ocean Research, Kiel, Germany*

### **Background**

Microorganisms associated with eukaryotic hosts are involved in various physiological functions, including chemical defense and immune responses. Production of bioactive molecules such as antibiotics and antifouling substances by associated bacteria, is one of the mechanisms to protect the host against pathogens, predation and surface colonization.

### **Objectives**

In this study, extracts from 10 bacterial strains isolated from the blue mussel, *Mytilus edulis* (Kiel Fjord, Baltic Sea, Germany), were screened for their antimicrobial activity against two panels of test microorganisms: a standard panel (*Escherchia coli*, *Bacillus subtilis* and *Candida albicans*) and environmental panel composed of strains isolated from the mussels (*Pseudomonas veronii*, *Bacillus pumilus* and *Shewanella baltica*).

### **Methods**

To identify isolated strains, PCR amplification of 16S rRNA was carried out and bioactivity tests were modified according to Schneemann et al. (2010) to evaluate the interaction of isolated strains with the test microorganisms.

### **Conclusions**

Inhibiting effects varied considerably among the test microorganisms, with *P. veronii* showing the most pronounced antibacterial activity against both the standard and the environmental panels. Moreover, the Gram-positive bacteria, and particularly *B. pumilus*, were generally more susceptible than Gram-negative strains, whereas no strain was found to inhibit growth of *E. coli*. These findings suggest that bacteria associated with the blue mussels may be involved in preventing pathogen invasions and that these hosts represent a promising source for the isolation of

antibiotic-active bacteria.

**Background** Cryptococcosis is a potentially fatal systemic mycosis, which is caused by *Cryptococcus neoformans*(Cn) and *C. gattii* (Cg). This disease is an opportunistic infection for AIDS. *Cryptococcus* is able to cause three types of infections, cutaneous cryptococcosis, pulmonar cryptococcosis and cryptococcal meningitis. The treatment recommended is the intravenous amphotericin B with flucytosine administered orally. This drug combination causes severe side effects and yeast-resistance, encouraging the search for innovative anti-*Cryptococcus* agents. **Objectives** The objectives of this work were synthesis of chalcone and hydroxychalcones, determination of antifungal activity against Cn and Cg strains, evaluation of cytotoxicity against mammalian cell lines, and evaluation of the inhibitory cell adhesion activity of Cn onto pneumocytes. **Methods** The chalcone and hydroxychalcones were synthesized by Claisen-Schmidt condensations. The anti-*Cryptococcus* activity was evaluated by microdilution test performed in 96-well plates, using CLSI-M27-A2 document. This assay demonstrated the values of Minimum Inhibitory Concentration (MIC) and Minimum Fungicidal Concentration (MFC) to five strains; Cn-ATCC90012, and four clinical isolates CnS, CnI, CnR and Cg118. The cytotoxicity was evaluated by MTT colorimetric assay, using five mamalian cell lines, A549, HepG2, MRC-5, U87-MG and NOK. **Conclusions** The hydroxychalcones exhibited potent antifungal activity, demonstrating MIC and MFC values ranging from 1.95 to 15.6µg/mL, which were related to high inhibition of Cn adhesion onto pneumocytes. In MTT assay, at 100µg/mL, these compounds were not toxic for all cell lines. We conclude that hydroxychalcones are antifungal hits, with relative selectivity for yeast, and their mode of action is related to inhibition of yeast adhesion onto host-cells.

**New antimicrobial mechanisms**

## **IN VIVO CLUSTER FORMATION OF NISIN AND LIPID II IS CORRELATED WITH MEMBRANE DEPOLARIZATION**

D. Scheffers<sup>1</sup>, M.B. Tol<sup>1</sup>, D. Morales-Angeles<sup>1</sup>

<sup>1</sup>Molecular Microbiology, University of Groningen, Groningen, Netherlands

### **Background**

Nisin and related lantibiotics can kill bacteria in two ways: by pore formation, which leads to membrane depolarization, or by sequestering Lipid II, which interferes with cell wall synthesis. Literature shows that during sequestration, nisin and Lipid II cluster into non-physiological domains, which are visible with fluorescence microscopy. Recently we observed that a reported 'non-pore' forming nisin mutant clusters LipidII, but also depolarizes the membrane (Lages *et al.*, 2013, Environm. Microbiol. 15, 3272).

### **Objectives**

To further investigate the relation between LipidII clustering and membrane depolarization.

### **Methods**

Microscopy, fluorescent assays to detect membrane integrity.

### **Conclusions**

We used *in vivo* assays to investigate how and when nisin forms pores, depolarizes the membrane, and segregates Lipid II into domains. By comparing the activity of pore-forming and pore-deficient mutants of nisin we show that clustering of nisin and Lipid II *only* occurs when (i) membrane integrity is reduced by pore formation and (ii) when the membrane is completely depolarized. Furthermore, pore-forming variants of nisin were also able to kill L-forms – which grow without a cell wall – whereas non-pore forming lantibiotics only kill bacteria with a cell wall. Our results have important implications for the mechanism-of-action of nisin. Because cluster formation never occurred with non-pore-forming lantibiotics, we suggest that lantibiotics either kill by pore-formation, or by occlusion of Lipid II for incorporation into the cell wall.

<sup>1</sup>Microbiology and Immunology,

Universidade Estadual Paulista "Júlio de Mesquita Filho"/UNESP, Botucatu, Brazil

### **Background**

Combinatory effect between conventional antimicrobial drugs and phytochemical products can be a new strategy to increase effectiveness of antibiotics.

### **Objectives**

We aimed to verify synergism between essential oils compounds from plants and antimicrobial drugs for methicillin-resistant *Staphylococcus aureus* (MRSA).

### **Methods**

Five essential oils compounds (citronellol, geraniol, eugenol, terpineol and cinnamaldehide) were tested against 10 strains of *S. aureus* MRSA. Mueller-Hinton agar (MHA) plus 0.5% Tween 80 was mixed with each compound ( $\frac{1}{4}$  of Minimal Inhibitory Concentration (MIC<sub>90%</sub>)). Nine antimicrobial drugs discs (oxacillin (1 µg), gentamicin (10 µg), erythromycin (15 µg), sulfazotrim (25 µg), vancomycin (30 µg), penicillin G (10 U) levofloxacin (5 µg), tetracycline (30 µg) and linezolid (30 µg)) were laid on culture medium inoculated with *S. aureus*. Assays were performed in duplicate. Mann-Whitney test was used as statistical. Time kill curves were performed between EOC and AD for positive cases. Treatments were incubated with 10<sup>5</sup> CFU/mL of MRSA strain in MH broth. Media without EOC and/or AD was used as control. Aliquots were removed at different time intervals between 0 and 24h. Viable colonies were counted after incubation (24 h/ 37°C) in order to obtain CFU/mL.

### **Conclusions**

The present study showed a promising way of treatment for diseases caused by MRSA as well as against other bacterial species, because time kill curves for EOC and AD demonstrated additive activity. Thereby, these compounds can be used in combination with conventional antimicrobials.

**SENSITIVITY OF MDR ACINETOBACTER BAUMANNII WOUND ISOLATES TO RUMEX SANGUINEUS, RUMEX CRISPUS AND URTICA DIOICA EXTRACTS**

V. Aleksic<sup>1</sup>, N. Mimica-Dukic<sup>2</sup>, E. Svircev<sup>2</sup>, M. Petrusic<sup>1</sup>, A. Petrovic<sup>1</sup>, P. Knezevic<sup>1</sup>

<sup>1</sup>Department of biology and ecology, Faculty of Sciences-University of Novi Sad, Novi Sad, Serbia

<sup>2</sup>Department of Chemistry Biochemistry and Environmental Protection, Faculty of Sciences-University of Novi Sad, Novi Sad, Serbia

**Background**

*Acinetobacter baumannii* is a pleomorphic, non-motile bacterium and etiological agent of various infections in immunocompromised patients. It has been characterized as a novel, drug resistant and rapidly emerging clinical pathogen with increasing prevalence. Regarding recent multi-drug resistant *A. baumannii* strains emergence, it is urgent to examine alternative antimicrobial agents, including various plant extracts.

**Objectives**

The aim of this study was to determine *in vitro* antimicrobial activity of *Rumex crispus*, *Rumex sanguineus* and *Urtica dioica* extracts against multi-drug resistant *A. baumannii* wound isolates.

**Methods**

The broth microdilution assay was used to determine minimal inhibitory concentrations (MIC) and minimal bactericidal concentrations (MBC) of 8 plant extracts obtained from different parts of the examined plants. For antibacterial activity testing 20 multiple resistant *A. baumannii* wound isolates and 2 reference strains (ATCC BAA-747 and ATCC 19606) were used.

**Conclusions**

*Urtica dioica* possessed no effect against *A. baumannii*, while *Rumex sanguineus* and *Rumex crispus* extracts showed significant antibacterial activity against all examined isolates. Bacteriostatic effect was obtained with concentrations 1 - 4 mg mL<sup>-1</sup> with median value 2 mg mL<sup>-1</sup>, while bactericidal activity was achieved with a slightly higher concentrations of *Rumex* extracts (1 to 8 mg mL<sup>-1</sup> with median 4 mg mL<sup>-1</sup>). The obtained result confirmed earlier detected antibacterial effect of *R. crispus* extracts against *A. baumannii*, while anti-*A. baumannii* activity of *R. sanguineus* extracts was detected for the first time. Accordingly, the plants from the genus *Rumex* are valuable source of bioactive compounds against this bacterium and antimicrobial activity of dominant extract components should be further examined.

<sup>4</sup>Host Microbes Interactomics Group, Wageningen University, Wageningen, Netherlands

<sup>5</sup>Veterinary Disease Biology, University of Copenhagen, Frederiksberg C, Denmark

#### Background

*Staphylococcus aureus* infections are becoming increasingly difficult to treat due to antibiotic resistance. Of particular concern are the community-associated methicillin-resistant *S. aureus* (CA-MRSA) strains such as USA300. Virulence of CA-MRSA is regulated by the *agr* quorum-sensing system, which in response to *agr*-encoded autoinducing peptides confines exotoxin production to the stationary growth phase with concomitant repression of surface-expressed adhesins. In need of novel treatment options, anti-virulence therapy, targeting virulence factors rather than viability, has been proposed. Solonamide B was recently isolated from a marine bacterium as a putative anti-virulence compound that markedly reduced expression of the toxins  $\alpha$ -hemolysin and the phenol-soluble modulins.

#### Objectives

To further strengthen the anti-virulence candidacy of Solonamide B and synthesized analogues.

#### Methods

Chemically synthesized solonamides and lactam analogues were validated for interference with *agr* virulence gene regulation, both quantitatively and qualitatively, using reporter fusion strains. The compounds' influence on biofilm formation and fibronectin binding of *S. aureus* were assessed as examples of complications related to *agr* negative strains; and lastly, toxicity of the compounds and the immune modulating capacity of solonamide-treated *S. aureus* were assessed on PBMCs, T-cell populations and DCs via flow cytometry.

#### Conclusions

We find that structural differences between solonamide analogues interfere differentially with *agr*, and that they do not display toxicity or influence immune cell activity and integrity. Importantly, our results also dismiss the major concern that application of compounds mimicking an *agr*-negative state may lead to adverse

interactions with host factors and immune cells.

**ANTIMICROBIAL EFFECT OF LIPOSOMES MODIFIED BY LYSOSOMAL MEMBRANE PROTEINS EXTRACTED FROM OVEREXPRESSED HSP70 IN *S. CEREVISIAE***

S. BANG<sup>1</sup>, Y. KIM<sup>2</sup>, J. MIN<sup>1</sup>

<sup>1</sup>*Division of Chemical Engineering, Chonbuk National University, Jeonju, Korea*

<sup>2</sup>*Department of Microbiology, Chungbuk National University, Cheongju, Korea*

**Background**

Preparation of liposome surface modified by various materials such as RNA, DNA or Proteins has been developed for several decades.

**Objectives**

We would like to investigate targeting ability of lysosomal membrane proteins related to killing bacteria through modifying the liposome surface to check the possibility of as antimicrobial agents whereby we tried to find specific membrane proteins.

**Methods**

Firstly, we used mixtures of lipid, cholesterol and lysosomal membrane protein isolated from lysosomes extracted from *S. cerevisiae* treated by H<sub>2</sub>O<sub>2</sub> and NH<sub>4</sub>Cl to modify liposome surface for antimicrobial activity after making liposomes prepared with hydration method. Liposomes were modified by lysosomal membrane proteins with two different methods in order to confirm the targeting ability.

**Conclusions**

The results showed that the antimicrobial activity was not shown without modification of liposome surface but it was better cell mortality in type 1 than type 2 method. Based on these results, we analyzed whole lysosomal membrane proteins by 2-DE assay to find specific proteins associated with antimicrobial activity and constructed recombinant *S. cerevisiae*. And then, we found the genes (HSP70) related to antimicrobial activity and prepared liposomes modified by lysosomal membrane proteins extracted from lysosomes isolated from recombinant *S. cerevisiae* tagged with GFP. The result showed that the antimicrobial activity of liposomes modified with Type1 method was better than control. Therefore, lysosomal membrane proteins for targeting bacteria will play an important a role.

**New antimicrobials for resistant organisms**

**DOUBLE LEADING: LANTIBIOTIC - MICROCIN HYBRIDS**

A. Buivydas<sup>1</sup>, M. Montalban-Lopez<sup>1</sup>, O.P. Kuipers<sup>1</sup>

<sup>1</sup>Molecular Genetics, University of Groningen, Groningen, Netherlands

**Background**

Lantibiotics and microcins form different groups of posttranslationally modified bacterial peptides mainly produced by Gram-positive and Gram-negative bacteria, respectively. Most of these peptides exhibit a potent antimicrobial activity, more active even than some antibiotics. Maturation of a peptide begins with a propeptide which is guided throughout specific modification events due to leader peptide (an amino acid sequence recognized by particular modification biomodule). The leader peptide is proteolitically removed in the last steps of peptide modification making the modified peptide active. Posttranslational modifications endorse lantibiotics and microcins with high target-specific activities and stability against proteolysis.

**Objectives**

To design plug-and-play biomodules for production of novel peptides containing both, lantibiotic- and microcin-specific posttranslational modifications.

**Methods**

We used a synthetic biology approach to design biomodules. We utilized peptide modification systems cloned under different controlled promoters to assure gradual and temporal activity of designed biomodules. Codon optimized synthetic genes of designed model peptides to be modified were employed together with modification machineries.

**Conclusions**

This is a unique case where posttranslational modifications from two different peptide classes are fused together into a single peptide chain *in vivo*. Here, we also show the possibilities of employing chimeric leader peptides for substrate recognition and procession by particular posttranslational modification machineries.

**New antimicrobials for resistant organisms**

**SILVER NANOPARTICLES WITH ANTIMICROBIAL ACTIVITY FOR BACTERIA  
GRAM POSITIVE, NEGATIVE AND YEAST**

A. Hamdan<sup>1</sup>, S. González<sup>1</sup>, T. López<sup>1</sup>, J. Bustos<sup>1</sup>

<sup>1</sup>Atención a la Salud, Universidad Autónoma Metropolitana - Xochimilco, Mexico City, Mexico

**Background**

Silver and its compounds have strong antimicrobial activities for bacteria, fungus, and viruses. Recent advances in researches made on metal nanoparticles appear to revive the use of silver nanoparticles (SNPs) for antimicrobial applications. It has been shown that SNPs prepared with a variety of synthetic methods have effective antimicrobial activity.

**Objectives**

In this work, silver nanoparticles (Ag NP) with 5% silver chloride (NanoRa<sup>2</sup>), were used to evaluate the antimicrobial activity against various bacteria Gram-positive, Gram-negative and yeasts.

**Methods**

Silver nanoparticles (NanoRa<sup>2</sup>) were synthesized with silver chloride to 5%, by the Sol-Gel method. Silver nanoparticles were characterized by SEM (Scanning Electron Microscope). Silver nanoparticles (NanoRa<sup>2</sup>) were tested for different Gram-positive bacteria as *Enterococcus faecalis*, *Staphylococcus aureus*, *Staphylococcus epidermidis*, and Gram-negative bacteria such as *Klebsiella pneumoniae*, *Escherichia coli*, *Pseudomonas aeruginosa*, *Proteus mirabilis* and *vulgaris*, as well as the yeast *Candida albicans*. The antibacterial activity of the silver nanoparticles was evaluated following the guidelines for the Kirby-Bauer diffusion method according to the CSLI.

**Conclusions**

Nanoparticles have a particle size of 100nm. The spectrophotometric profile showed characteristic IR peaks, links titanium dioxide that have the NanoRa<sup>2</sup>. The silver nanoparticles were able to inhibit the growth of Gram-positive, Gram-negative and yeasts from 10 ppm and 50 ppm. In the case of *Staphylococcus aureus* methicillin resistant as well as *Candida albicans*, the silver nanoparticles at a concentration of 50 ppm, larger zones of inhibition were showed.

#### **P113-DERIVED PEPTIDES AS NOVEL INHIBITORS FOR DRUG-RESISTANT CANDIDA SPP.**

G. Lin<sup>1</sup>, H. Chen<sup>1</sup>, M. Liu<sup>2</sup>, C. Lan<sup>1</sup>, W. Cheng<sup>2</sup>

<sup>1</sup>*Institute of Molecular and Cellular Biology and Department of Life Sciences, National Tsing Hua University, Hsinchu, Taiwan*

<sup>2</sup>*Department of Research & Development, General Biologicals Corporation, Hsinchu, Taiwan*

#### **Background**

*Candida* spp., major opportunistic pathogens, infects immunocompromised people and is responsible for life-threatening infections. The individuals commonly affected include those with oral candidiasis of HIV-positive patients, cancer patients undergoing radiotherapy, and xerostoma patients. *Candida* infections may further result in severe systemic infection and convert multiple organ failure (1). Moreover, *Candida* spp. can develop resistance to multiple antifungal drugs by over-expression of drug resistance-related targets.

#### **Objectives**

In this study, we developed a patented anti-fungal peptide P-113 to overcome the emerging issue of drug-resistance in *Candida* infections. We also modified P-113 by tandemly repeating sequences to improve the candidacidal efficiency.

#### **Methods**

The P-113, derived from human histatin-5 protein, retains a full antibacterial activity and exhibits a wide spectrum of activity in vitro against both bacteria and fungi (2). Several drug- (azoles-) resistant clinical strains including *C. albicans*, *C. krusei*, *C. glabrata*, and *C. tropicalis* were isolated from oral candidiasis patients. We investigated the susceptibility of these drug-resistant strains to P-113 by candidacidal assay (3).

#### **Conclusions**

The results showed that P-113 was able to kill these drug-resistant strains, suggesting a promising candidacidal activity of P-113 toward drug-resistant *Candida* spp. To improve the candidacidal activity, we designed P-113-derived dimeric and trimeric peptides which contain 2- and 3-time tandem repeats. The two tandem repeats improved the candidacidal potency of the peptides, and the dimer and trimer

have  $IC_{50}$  values against *C. albicans* of 0.5 and 0.4  $\mu M$ , respectively, compared with the monomer P-113 ( $IC_{50} = 2.3 \mu M$ ). P-113 and its derivatives show a potential for the development of novel therapeutics against *Candida* infections.

**SYNERGISM OF FLORFENICOL IN COMBINATION WITH ANALOG  
THIAMPHENICOL AGAINST STAPHYLOCOCCUS HYICUS, STREPTOCOCCUS  
SUIS, AND PASTEURELLA MULTOCIDA**

C.F. Wei<sup>1</sup>, J.H. Shien<sup>1</sup>, S.K. Chang<sup>2</sup>, H.C. Kuo<sup>3</sup>, C.C. Chou<sup>1</sup>

<sup>1</sup>Department of Veterinary Medicine, National Chung Hsing University, Taichung, Taiwan

<sup>2</sup>Graduate Institute of Veterinary Medicine, National Taiwan University, Taipei, Taiwan

<sup>3</sup>Department of Veterinary Medicine, National Chiayi University, Chiayi, Taiwan

**Background**

Florfenicol (FF) and thiamphenicol (TAP) are amphenicol antibiotics commonly used in veterinary and aquiculture practice with broad-spectrum antibacterial activity. Previous study found that FF and TAP exhibited synergistic effect against *Staphylococcus aureus* (including methicillin-resistant) clinical isolated strains.

**Objectives**

To further investigate the spectrum of synergistic activities of FF and TAP combination.

**Methods**

The antibacterial activities of FF and TAP combination against a total of 69 strains of *Salmonella enterica*, *Pasteurella multocida*, *Pseudomonas aeruginosa*, *Riemerella anatipestifer*, *Streptococcus suis*, and *S. hyicus* were evaluated by checkerboard assay and time-kill study. For protective effects of combination therapy on chicken, FF and TAP alone or in combination were administered intramuscularly 30 mins prior to the intramuscular infection of *P. multocida*.

**Conclusions**

The checkerboard assay showed additive effect ( $0.5 \leq$  fractional inhibitory concentration (FIC) index  $\leq 1$ ) of FF/TAP combination in 75% of *P. multocida*, 53% of *S. suis*, 50% of *S. hyicus*, 33% of *P. aeruginosa* and 11% of *S. enterica* isolates that also include FF and TAP-resistant strains. In addition, 8 strains of *P. multocida*, *S. suis*, and *S. hyicus* were further demonstrated in the time-kill study confirming synergism between these two drugs. It also appeared that the combination enhanced the bacteriostatic effect to bactericidal on the 3 bacteria. Most notably, the *P. multocida*-challenged chickens were effectively protected by FF /TAP combination at lower dosages. Present study demonstrated the potentiality of a novel combination regimen of the same class of antibiotics against *P. multocida* infections.

#### **DISCOVERY OF NEW ANTIMICROBIALS FROM ACTINOALLOMURUS**

J. Cruz<sup>1</sup>, M. Iorio<sup>2</sup>, S. Maffioli<sup>2</sup>, A. Bernasconi<sup>2</sup>, C. Brunati<sup>2</sup>, M. Sosio<sup>2</sup>, S. Donadio<sup>2</sup>

<sup>1</sup>Ktedogen, Ktedogen SRL, Milano, Italy

<sup>2</sup>NAICONs, NAICONs SRL, Milano, Italy

#### **Background**

These past few years have been changing dramatically the landscape of infectious diseases, showing that investment on drug discovery should not be disregarded as a steady emergence and spread of antibiotic resistance keeps occurring and giving origin to more multi-drug resistant strains. One possible source to enhance the antibacterial arsenal is to look on what Nature has been using to solve the very same problem. With the myriad of species waiting to be scrutinized, it is wise to give priority to those less exploited but phylogenetically related to known producers.

#### **Objectives**

This project is part of a screening program designed to assess the metabolic potential of the recently described genus *Actinoallomurus*, and to deliver new molecular structures.

#### **Methods**

The program includes small-scale fermentations followed by in vitro and in vivo bioactivity tests on fermentation broths extracts. Positive samples are then subjected to a combination of bioassays and chemical analysis (HPLC, MS and NMR and a query within ABL (a proprietary antibacterial database) to determine the novelty of active compounds and discard those already known.

#### **Conclusions**

Our study shows *Actinoallomurus* carries the biosynthetic machinery to create a vast range of different active molecules. The dereplication process of 200 *Actinoallomurus* microbial extracts revealed the potential to produce a broad range of chemical classes, from lantipeptides to new hyperhalogenated angucyclines or aromatic polyethers. The diversity of the clusters of secondary metabolism found in the sequenced genome of an *Actinoallomurus*, seems to corroborate the theory that this genus may become an important producer of new active molecules.

<sup>3</sup>Department of Microbiology,

School of Medicine Tehran University of Medical Sciences, Tehran, Iran

**Background**

The human pathogen *Staphylococcus aureus* is responsible for many hospital-associated and community-acquired infections. The emergence of methicillin-resistant *S. aureus* (MRSA) and vancomycin resistant *S. aureus* strains have prompted research into staphylococcal vaccines and preventive measures. Staphylococcal clumping factor A (ClfA), iron surface determinant B (IsdB) and gamma hemolysin B (HlgB) are key virulence factors and opsonic activity plays an important role in successful vaccine development against *S. aureus* infections.

**Objectives**

In this report, the BALB/c mice were immunized with a recombinant protein (CIH) composed of selected antigenic regions of ClfA, IsdB and HlgB of *S. aureus*. After the immunization, opsonophagocytic activity assay (OPK) was performed to all serum samples.

**Methods**

After exposing the opsonized bacteria with peritoneal macrophages, The phagocytic capacity of macrophages exposed with serum from mice immunized with recombinant protein CIH showed a significant increase as compared with macrophages exposed with serum from mice immunized with PBS ( $p=0.002$ ).

**Conclusions**

Our finding indicated, that immunization of BALB/c mice with recombinant protein CIH promotes the phagocytosis of *S. aureus* and enhances the clearance of the *in vivo* pathogen.

<sup>2</sup>Restorative Dentistry, Univ Estadual Paulista UNESP, São José dos Campos, Brazil

#### **Background**

Due to the resistance of microorganisms to antibiotics, studying alternative methods such as plant extracts becomes very important.

#### **Objectives**

Evaluating the *in vitro* antifungal activity of *Persea americana* extract on *C. albicans* biofilm and its cytotoxicity in macrophage culture (RAW 264.7).

#### **Methods**

For the determination of the minimum inhibitory concentration (MIC), microdilution in broth (M27-A2 standard) was performed. Thereafter, the concentrations of 12.5, 25, 50, 100 and 200 mg/mL (n=10) with 5 min exposure were analyzed on mature biofilm in microplate wells for 48 h. Saline was used as control (n=10). After treatment, biofilm cells were scraped off and dilutions were plated on Sabouraud dextrose agar. After incubation (37°C /48 h), the values of colony forming units per milliliter (CFU/mL) were converted to log10 and analyzed (ANOVA and Tukey Test, 5%). The cytotoxicity of the *P. americana* extract was evaluated on macrophages by MTT assay.

#### **Conclusions**

Results: The MIC of the extract was 6.25 mg/mL and with 12.5 mg/ml there was elimination of 100% of planktonic cultures. Regarding the biofilms, a significant reduction (p

Conclusion: *P. americana* extract showed antifungal activity against *C. albicans* biofilm, whereas the concentration of 50 mg/mL presented the best results.

D. masoud<sup>1</sup>, S. tarashi<sup>1</sup>

<sup>1</sup>depatment of microbiology, shahid beheshti university of medical siences, Tehran, Iran

**Background**

*Pseudomonas aeruginosa* is one of the leading nosocomial pathogens. In recent years, inappropriate use of antibiotics is the cause of untreatable 'superbugs' and high death rates in clinics worldwide. One of the mechanisms of resistance to carbapenem antibiotics in *P. aeruginosa* is metallo- $\beta$ -lactamases (MBLs) production that hydrolyzes all carbapenems that are the last generation of drugs for treatment of infections caused by MDR *P. aeruginosa*.

**Objectives**

The aim of this study is evaluating the effects of *Myrtus communis* leaves and *ziziphus* leaves methanolic extract on IMP-Type metallo-beta-lactamase producing *P. aeruginosa* strains.

**Methods**

This experimental study was carried out on hospitalized burn patients during 2012-2013. Antibiotics and extracts susceptibility tests were performed by disc diffusion and broth microdilution methods. MBL detection was performed by Combination Disk Diffusion Test (CDDT). The bla(VIM) and bla(IMP) genes were detected by PCR and sequencing methods.

**Conclusions**

It was found that among 83 imipenem resistant *P. aeruginosa* strains, 48 (57.9%) were MBL producers. PCR and sequencing methods proved that these isolates were positive for blaIMP-1 genes, whereas none were positive for bla(VIM) genes. All MBL-producing *P. aeruginosa* were resistant to Meropenem, Imipenem, Ceftazidime, Amikacin, Tobramycin, Ciprofloxacin, Aztreonam, Piperacillin/Tazobactam, Ceftriaxone, Cefepime and Carbenicillin. The result of MIC for imipenem was 128( $\mu$ g/ml) for all strains. The MIC (mg/ml) and MBC (mg/ml) results of *Myrtus*

*communis* was 6.25 and 12.5 (mg/ml) for all isolates, *respectively* Although the ziziphus leaves methanolic extract represent any significant result on this isolates.

<sup>4</sup>*Department of Pharmacy, University of Naples Federico II, Naples, Italy*

<sup>5</sup>*Institute of Bioimaging and Biostructures, National Research Council, Naples, Italy*

**Background**

The huge increasing of bacterial strains resistant to classical antibiotics is threatening the public health security, thus the need of developing new antimicrobials has become critical. Cationic Antimicrobial Peptides (CAMPs) represent suitable alternatives, since they do not lead to selection of resistant strains. Indeed, CAMPs act by disrupting the membrane integrity and/or by altering its potential, so that, to acquire resistance bacteria need to remodulate the membrane composition. Such modifications could be detrimental to bacterial cells, thus dramatically reducing the onset of resistant strains.

**Objectives**

Although proteins involved in the immune response of multicellular eukaryotes represent a natural source of CAMPs, new methodologies for their identification are required to encounter the rising demand of more active and stable CAMPs.

**Methods**

A powerful bioinformatics tool has been recently set up and used to predict the antibacterial activity of cryptic CAMPs (i.e. embedded in the primary structure of proteins). Given their hydrophobic/cationic nature, sequences of transcription factors were chosen as source of choice for the discovery of new cryptic CAMPs. In particular, our analysis focused on extremely stable proteins from thermophilic *Archaea*.

**Conclusions**

Among the identified CAMPs, one from the DNA-binding protein Stf76 (here named PepC) has been structurally and functionally characterized. This peptide has the capability of inducing both membrane fusion and pore formation. Interestingly, the DNA-binding activity was retained opening the way to speculate about novel mechanisms of action. Moreover, its antimicrobial activity has been proved on clinical strains isolated from patients affected by cystic fibrosis.

**New antimicrobials for resistant organisms**

**ANTAGONISTIC ACTIVITY OF MARINE SPONGE-ASSOCIATED BACTERIA  
COLLECTED AT WIMEREUX (FRANCE) AGAINST CLINICAL STRAINS**

L. Goetghebuer<sup>1</sup>, M.S. Laport<sup>2</sup>, M. Bauwens<sup>1</sup>, I.F. George<sup>1</sup>

<sup>1</sup>*Ecologie des Systèmes Aquatiques, Université Libre de Bruxelles, Brussels, Belgium*

<sup>2</sup>*Departamento de Microbiologia Médica Laboratório de Bacteriologia Molecular e Marinha, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil*

**Background**

Marine sponges are an important -and yet understudied- reservoir of new antimicrobials, a majority of which are produced by associated microbes.

**Objectives**

We tested the antibacterial activity of 110 bacterial strains isolated from two sponges (*Halichondria panicea* and *Hymeniacidon perelvis*) collected off rocky substrate in the low intertidal zone at Wimereux, France.

**Methods**

Strains were isolated on various media (R2A, Brain Heart Infusion (BHI)-agar and Marine agar) and tested against three target clinical strains : *Pseudomonas aeruginosa* ATCC 27853, *Escherichia coli* ATCC 25922 and *Staphylococcus aureus* ATCC 2913. Antagonistic activity was measured in double layer agar assays.

**Conclusions**

Fifty strains (45%) were able to inhibit the growth of at least one clinical strain (most often *S. aureus*). Antibacterial-producing strains belonged to Gamma-*Proteobacteria* (88%, mostly *Pseudomonas* spp.) and *Firmicutes* (12%, among which *Lactococcus* spp. and *Vagococcus* spp.). The production of antimicrobial substances turned out to be modulated by the medium formulation, its salinity (tested from 0.5 to 3.5%) and the temperature used in antagonism assays (tested from 8 to 25°C). The best results were obtained with BHI-agar, the lowest salinity and highest temperature tested. In all cases, antimicrobial substances were not soluble, as the antagonistic activity was lost when cultures were filtered on 0.2 mm-pore membranes. This study confirmed the potential of sponge-associated microbes for the production of antibacterial substances.

#### **ISOLATION AND CHARACTERIZATION OF NOVEL BACTERIOPHAGES WITH LYTIC ACTIVITY AGAINST MULTIDRUG RESISTANT PATHOGENS**

S. Latz<sup>1</sup>, A. Wahida<sup>1</sup>, A. Arif<sup>1</sup>, K. Ritter<sup>1</sup>, H. Horz<sup>1</sup>

<sup>1</sup>Department of Medical Microbiology, Medical Faculty RWTH Aachen, Aachen, Germany

#### **Background**

With the emerging threat of infections caused by multidrug-resistant bacteria and scarce prospects of newly introduced antibiotics in the future, bacteriophages (phages) are currently being reconsidered as alternative therapeutics. However, the full breath of phage diversity suitable for treatment of bacterial infections is still largely unexplored.

#### **Objectives**

This study aims at providing an overview of the general occurrence of bacteriophages (with therapeutic potential) in natural environments and at devising strategies for their rapid characterization and classification at molecular level.

#### **Methods**

Novel phages were isolated from various aquatic systems (e.g. from general and hospital wastewater, activated sludge samples from sewage plants, streams, rivers, ponds and lakes). Environmental samples were pre-incubated with clinical isolates of multidrug-resistant bacteria. Enriched bacteriophages were subsequently obtained with the double agar layer plaque assay. "PhiSigns"

(<http://www.phantome.org/phisigns/>) was used for phage identification based on the detection of signature genes. Genomic comparison of phages was performed based on digitized fluorescent restriction-fragment-length-polymorphism-analysis (fRFLP).

#### **Conclusions**

For roughly 50% of tested bacterial strains lytic bacteriophages were found against multidrug-resistant *Pseudomonas aeruginosa*, *Klebsiella pneumoniae* and *Enterobacter* sp. with waste water samples harbouring the highest phage diversity. By contrast no bacteriophages were isolated against multidrug-resistant *Staphylococcus aureus* and *Acinetobacter baumannii*. PhiSigns combined with fRFLP proofed to be a useful tool for rapid phage identification, which is the base for their proper selection for ultimate whole genome sequencing. *S. aureus* and *A. baumannii* phages require additional isolation steps such as FeCl<sub>3</sub>-precipitation and/or use of

subinhibitory antibiotic-concentrations for enhancing plaque visibility on agar plates.

**ANTIFUNGAL ACTIVITY OF ESSENTIAL OIL FROM ABIES HOLOPHYLLA  
MAXIM AGAINST DERMATOPHYTES**

S. Kim<sup>1</sup>, C. Hong<sup>1</sup>, S. Lee<sup>2</sup>, M. Park<sup>2</sup>, I. Choi<sup>1</sup>, I. Choi<sup>3</sup>

<sup>1</sup>Forest Sciences, Seoul National University, Seoul, Korea

<sup>2</sup>Forest Resources Utilization, Korea Forest Research Institute, Seoul, Korea

<sup>3</sup>Research Institute of Agriculture and Life Sciences, Seoul National University, Seoul, Korea

**Background**

Dermatophytes are well known for one of world-wide cause of diseases such as tinea pedis, tinea cruris, and tinea corporis. Dermatophytes infections are increasing of taking antifungal agents, accordingly increased side effects like toxicity and tolerance. That was why searches on natural antifungal medicine have motivated. Many kinds of woody essential oils have antifungal activity, especially essential oils of conifers. *Abies holophylla* Maxim (AH) is widespread in East Asia and its essential oil was known to have effective antifungal actions against *Aspergillus fumigatus*.

**Objectives**

Therefore, this study was to investigate the antifungal activity of AH essential oil against dermatophytes, such as *Epidermophyton floccosum*, *Trichophyton mentagrophytes* and *Trichophyton rubrum*, and to determine the potential effective compound as dermatitis treatment.

**Methods**

To evaluate the potential antifungal activities of AH essential oil and its fractions, Minimum Inhibitory Concentration (MIC) measurement and agar dilution method were used with morphological observation. Also, their major constituents were analyzed by GC/MS. The morphological changes of the dermatophytes exposed to the AH essential oil were observed by electron microscopes.

**Conclusions**

As the results, the highest activities were identified in the fraction containing borneol, limonene, 3-carene, and camphene. Also, morphological observation using electron microscopes (SEM and FEM) showed a dramatic changes of cell wall of dermatophytes exposed to the AH essential oil. In conclusion, AH essential oil and its constituents were expected to be used as antifungal agent or raw material for dermatitis therapy.

**IN VITRO ANTI-STAPHYLOCOCCAL ACTIVITY OF SECONDARY METABOLITES FROM DROSERA BINATA COMBINED WITH SILVER NANOPARTICLES**

M. Krychowiak<sup>1</sup>, M. Grinholc<sup>1</sup>, R. Banasiuk<sup>1</sup>, M. Krauze-Baranowska<sup>2</sup>, D. Głód<sup>2</sup>, A. Kawiak<sup>1</sup>, A. Królicka<sup>1</sup>

<sup>1</sup>Department of Biotechnology, Intercollegiate Faculty of Biotechnology UG-MUG, Gdansk, Poland

<sup>2</sup>Department of Pharmacognosy, Faculty of Pharmacy with Subfaculty of Laboratory Medicine, Gdansk, Poland

**Background**

Antibiotic resistant *Staphylococcus aureus* is a serious nosocomial pathogen and the major cause of life threatening infections, like burn wound infections. There is an urgent need to overcome antibiotic resistance by developing new antimicrobial treatment. The use of active plant secondary metabolites simultaneously with silver nanoparticles (AgNPs) against *S. aureus* is based on multi-target strategy.

**Objectives**

The aim was to find an alternative anti-staphylococcal treatment based on the combination of *Drosera binata* secondary metabolites and silver nanoparticles.

**Methods**

Plant extracts were obtained from *in vitro* cultured *D. binata* tissues. Antibacterial activity was determined by Broth Microdilutions Method. Checkerboard Titration technique was used to study interactions between AgNPs and extracts or secondary metabolites. Composition of the extract was established by the HPLC-MS analysis. The MTT Assay was used to evaluate cytotoxicity of antimicrobial agents towards *in vitro* cultured human keratinocytes.

**Conclusions**

Both silver nanoparticles and the *D. binata* extract possess antibacterial activity towards various *S. aureus* strains regardless of their antibiotic resistance. The synergistic bactericidal activity was observed when AgNPs and plant extracts were combined. This allowed to significantly reduce the bactericidal concentrations of AgNPs and the extract by 50% and 97%, respectively. Among all extract constituents only the chlorine derivative of plumbagin (ChPL) showed synergistic bactericidal activity with AgNPs. Moreover, reduced bactericidal concentrations of mixtures of

AgNPs with the extract or ChPL were observed to be non-cytotoxic towards human keratinocytes. Obtained results indicate that combination of AgNPs and secondary metabolites from *D. binata* tissues may provide an alternative antimicrobial treatment.

**New antimicrobials for resistant organisms**

**ANTIBACTERIAL AND ANTIFUNGAL ACTIVITY OF NEWLY SYNTHESISED  
BENZOXABORoles, BENZOSILOXABORoles AND PYRIDOXABORoles**

A.E. Laudy<sup>1</sup>, K. Stepień<sup>1</sup>, S. Lulinski<sup>2</sup>, K. Durka<sup>2</sup>, I. Steciuk<sup>2</sup>, S. Tyski<sup>1</sup>

<sup>1</sup>*Pharmaceutical Microbiology, Medical University of Warsaw, Warsaw, Poland*

<sup>2</sup>*Faculty of Chemistry, Warsaw University of Technology, Warsaw, Poland*

**Background**

Benzoxaboroles, and related compounds, are a particularly interesting group of synthetic agents. Their diverse biological activities and widespread applications in medicinal chemistry have undergone intense scientific investigation.

**Objectives**

We have examined whether new benzoxaborole-based derivatives and their analogues possess antimicrobial activity and are substrates for multi-drug-resistance efflux pumps.

**Methods**

The antibacterial and antifungal activities of newly synthesised compounds: 3 benzoxaborole-, 3 benzosiloxaborole- and 6 pyridoxaborole-based derivatives were evaluated. Antimicrobial activity was screened using the disc-diffusion test (0.4mg of the derivative was applied to a filter paper disc). The MIC and MBC values were estimated according to CLSI and EUCAST recommendations. During determination of MIC values  $\pm$  PAbN (80mg/L), the concentrations of tested compounds in the broth medium ranged: 0.39-400mg/L. The 19 reference ATCC strains of Gram-positive, Gram-negative bacteria and yeast were used in this study.

**Conclusion:**

Generally, the most potent antibacterial and antifungal activities were found for fluorine substituted benzosiloxaboroles – analogues of benzoxaboroles possessing a silicon atom for carbon substitution at the 3-position (MICs 25-400mg/L and 0.78-100mg/L, respectively). Interestingly, the B(OH)<sub>2</sub>-substituted 3-phenylbenzoxaboroles were found to be the most potent against Gram-positive cocci: *Staphylococcus* sp. (MICs 12.5-50mg/L), *Enterococcus* sp. (MIC 200mg/L) and yeasts (MIC 50mg/L). Furthermore, we demonstrated that benzoxaboroles were removed by efflux pumps present in Gram-negative bacteria. Of note, only two pyridoxaborole-based compounds were found to be weakly active against *Staphylococcus* sp.

These data demonstrate structure-activity relationships of the tested derivatives and

highlight the need need for futher investigations into the antimicrobial properties of new benzoxaboroles and related compounds.

#### APPLICATION OF A HIGH-THROUGHPUT ASPERGILLUS FUMIGATUS CELL WALL STRESS REPORTER SYSTEM: IDENTIFICATION OF SYNTHETIC PEPTIDES INCREASING THE SENSITIVITY FOR ANTIFUNGAL MEDICINES

B.C. Lokman<sup>1</sup>, E.L. Lagendijk<sup>2</sup>, S. Hakken<sup>3</sup>, A.F.J. Ram<sup>2</sup>, C. van den Hondel<sup>4</sup>

<sup>1</sup>HAN BioCentre, HAN University of Applied Science, Nijmegen, Netherlands

<sup>2</sup>Institute of Biology, Leiden University, Leiden, Netherlands

<sup>3</sup>HAN BioCentre, HAN University of applied science, Nijmegen, Netherlands

<sup>4</sup>HiTeXacoat, HiTeXacoat, Gouda, Netherlands

#### Background

Increased resistance to currently used antifungal compounds and the fact that these agents are often harmful to man and environment have resulted in a growing demand for new antifungals, which selectively act on cellular processes that are unique to fungi. To meet this demand, we have established in *A. niger* a luciferin/luciferase based reporter system for high-throughput screening of natural products for identification of potential new antifungal drugs.

#### Objectives

Our system allows us to identify compounds that specifically inhibited the fungal cell wall biosynthesis.

#### Methods

Recently the system has been developed for *A. fumigatus* and non-*Aspergillus* species. The system was validated by analyzing its performance with several antifungal drugs which are commonly used in the clinic like Caspofungin, Amphotericin B, Voriconazol (V fend) as well as Nikkomycin. A dose response behavior of the compounds could be demonstrated together with in time different types of stress responses. Importantly, whether the compound tested is fungistatic or fungicidal could be clearly indicated.

Subsequent analysis of different synthetic antimicrobial peptides, HTX1-4, revealed also a moderate effect on cell wall stress induction indicated by an increase in Lux activity.

#### Conclusions

Interestingly, incubation of these peptides at sublethal concentrations together with some of the antifungal medicines showed a considerable increase in lux activity

and a significant increase in sensitivity of *A.fumigatus* for these medicines. Growth test with sublethal concentrations of HTX-2 on EBV-LCL, K562 cells and PHA-blasten, and also cytotoxicity- and genotoxicity tests with NCTC2544 cells did not show any negative/toxic effects on these human cell lines.

### **New antimicrobials for resistant organisms**

#### **PRODUCTION OF NEW-TO-NATURE HYPERMODIFIED LANTIBIOTICS**

M. Montalban-Lopez<sup>1</sup>, D. Mu<sup>1</sup>, A.J. van Heel<sup>1</sup>, O.P. Kuipers<sup>1</sup>

<sup>1</sup>Molecular Genetics, University of Groningen, Groningen, Netherlands

#### **Background**

Lantibiotics are potent peptide antimicrobials active against Gram-positive bacteria, including multidrug resistant pathogens. They display various posttranslational modifications, with lanthionine rings and dehydroamino acids as key signatures of this family of antimicrobials. In addition, some lantibiotics contain other enzymatic modifications that have a role in their activity.

#### **Objectives**

Our purpose is to combine different enzymes from diverse lantibiotic production systems in order to hypermodify the model lantibiotic nisin as a proof-of-principle. This can set a methodology for the design and modification of other (antimicrobial) peptides.

#### **Methods**

We have combined, in either *Lactococcus lactis* or *Escherichia coli*, the modification machinery of nisin (the dehydratase NisB, the cyclase NisC) with the hydroxylases MibO and CinX from the microbisporicin and the cinnamycin machineries, respectively; the C-terminal decarboxylase GdmD from the gallidermin cluster; and the reductase LtnJ from the lactacin 3147 system.

#### **Conclusions**

We have generated nisin derivatives containing hydroxyproline, hydroxyaspartate, a C-terminal aminovinyl-cysteine, or D-alanine in their structure. Moreover we have confirmed that these additional enzymes do not require leader peptide recognition to modify their substrate.

Our results provide an insight for the application of Synthetic Biology for the design and *à la carte* modification of (antimicrobial) peptides.

**New antimicrobials for resistant organisms**

**THERAPEUTIC MONOCLONAL ANTIBODIES AGAINST THE GLOBALLY SPREAD MULTI-DRUG RESISTANT ESCHERICHIA COLI CLONE ST131-O25B:H4**

G. Nagy<sup>1</sup>, V. Szijártó<sup>1</sup>, L. Guachalla<sup>1</sup>, Z. Visram<sup>1</sup>, E. Nagy<sup>1</sup>

<sup>1</sup>*Microbiology and in vivo Models, Arsanis Biosciences GmbH, Vienna, Austria*

**Background**

The globally spread multi drug resistant *E. coli* clone ST131-O25b:H4 is responsible for a significant proportion of multi-drug resistant extraintestinal infections. By definition, isolates of this clone express the O25b antigen, whose unique structure has been resolved recently.

**Objectives**

We aimed to develop humanized monoclonal mAbs against the O25b antigen that may provide an alternative adjunct or stand-alone therapeutic option against this *E. coli* lineage.

**Methods**

Murine mAbs against the unique O25b antigen were generated by standard hybridoma technique. Following a primary screening, selected antibodies were subjected to humanization. Specificity and binding characteristics were assessed by immunoblots and ForteBio using purified antigens. Surface staining of ST131-O25b isolates irrespective of the capsular type expressed was shown by flow cytometry. Upon surface binding, the humanized antibodies induced complement mediated bactericidal activity *in vitro*. Passive immunization with the humanized mAbs elicited high level of protection at low mAb doses in a murine model of bacteremia. All whole cell assays were performed with bacteria grown in standard culture medium as well as in depleted pooled human serum in order to mimic *in vivo*-like conditions.

**Conclusions**

Humanized mAbs against *E. coli* O25b antigen were developed that elicited bactericidal activity *in vitro* and showed protection *in vivo*. Prophylactic passive immunization of colonized individuals or adjunct therapy of infected patients by mAbs may replace/substitute antibiotic therapy against this drug resistant clone. Relevant cases could be identified by the co-developed companion diagnostic tool.

**FREE AND IMMOBILIZED PHOTSENSITIZERS FOR ERADICATION OF PATHOGENIC BACTERIA**

*F. Nakonechny<sup>1</sup>, Y. Ilizirov<sup>1</sup>, Y. Mualem<sup>1</sup>, K.A. Raik<sup>1</sup>, M. Gutterman<sup>1</sup>, A. Valkov<sup>1</sup>*

*<sup>1</sup>Chemical Engineering Biotechnology and Materials, Ariel University, Ariel, Israel*

**Background.** The problem of controlling microbial infections remains one of the most serious challenges faced by mankind, despite the development of very effective antimicrobial agents. Bacterial resistance to antibiotics, which for decades were considered to be capable of combating any bacterial infection, actually destroyed hopes for combating pathogenic bacteria. One of alternatives to antibiotic treatment is photodynamic antimicrobial chemotherapy based on visible light-activation of dyes called photosensitizers. In the dark, these photosensitizers are non-toxic or have low toxicity. No bacterial resistance to photosensitizers has been reported to date.

**Objectives.** The present report is dedicated to the antibacterial activity of the photosensitizers Rose Bengal and Methylene Blue against Gram-positive *Staphylococcus aureus*. The antimicrobial activity of both free and immobilized photosensitizers was examined.

**Methods.** Rose Bengal and Methylene Blue were immobilized on polystyrene, polycarbonate and poly(methyl methacrylate) by dissolution in chloroform with further evaporation of the organic solvent and the formation of thin polymeric films. Immobilization of these photosensitizers on polyethylene and polypropylene was performed by dissolution in the melted polymers. The free and immobilized photosensitizers showed high efficiency in eradication of *S. aureus* as tested by the MIC, the colony-forming units count and measurement of the inhibition zone.

**Conclusions.** Photodynamic inactivation of *S. aureus* by Rose Bengal and Methylene Blue opens prospects for developing an alternative to antibiotic treatment of bacterial infections.

## **ANTIMICROBIAL PEPTIDES OF MARINE ORIGIN AND THEIR MOLECULAR CHARACTERIZATION**

R. PHILIP<sup>1</sup>, V.V. Afsal<sup>1</sup>, S.P. Antony<sup>2</sup>, N. Sathyan<sup>1</sup>, E.R. Chaithanya<sup>1</sup>,  
I.S. Bright Singh<sup>2</sup>

<sup>1</sup>Department of Marine Biology Microbiology and Biochemistry,  
Cochin university of Science and Technology, Cochin, India

<sup>2</sup>National Centre for Aquatic Animal Health,  
Cochin university of Science and Technology, Cochin, India

### **Background**

Marine organisms are continuously exposed to microbial population and are equipped with effective immune molecules to combat microbial invasion. Antimicrobial peptides are important components of innate defense mechanisms exhibited by animals. These organisms produce a range of AMPs varying greatly in size, structure and other physicochemical properties. Investigating novel antimicrobial peptides from marine organisms can provide new insight into the immune response of these organisms and a possibility of discovering new and effective drugs in medicine/aquaculture.

### **Objectives**

Screening marine organisms for discovering novel antimicrobial peptides

### **Methods**

Total RNA was extracted from haemocytes and cDNA was synthesized. PCR amplification was done using gene specific primers for AMPs. Amplicons were cloned and sequencing of the inserts were done at SciGenom, India. Homology search was performed by using BLASTn and BLASTp at NCBI and physio- chemical characterization by ProtParam Tool. Phylogenetic tree was constructed based on amino acid sequences by Neighbor joining method using MEGA 5.0

### **Conclusions**

Four novel ALF isoforms were characterized, among which two were identified from crabs (*Scylla serrata* and *Portunus pelagicus*) and two from shrimp (*Fenneropenaeus indicus*). Four novel isoforms of crustins were also identified and characterized from *Scylla serrata*, *Scylla tranquebarica*, *Portunus pelagicus* and *Fenneropenaeus indicus*. Two penaeidin isoforms were characterized from *Fenneropenaeus indicus* and *Penaeus monodon* and a hepcidin from *Chlorophthalmus bicornis*. The marine environment, with its enormous biodiversity remains a largely untapped reservoir of bioactive peptides. Recombinant expression and bioactivity testing of these peptides

will definitely contribute to the design and formulation of potential peptide drugs for application in medical/ aquaculture industry.

#### **RESEARCHANT HUB: THE FIRST ONLINE PLATFORM FOR EXPERIMENTAL COMPOUND SHARING**

M.L. Wu<sup>1</sup>, R.J.A. Rademakers<sup>1</sup>, P. de Jonge<sup>1</sup>, S. van der Zwart<sup>1</sup>, B. van Buuren<sup>1</sup>, M. Heeneman<sup>1</sup>

<sup>1</sup>ResearchAnt Hub, ResearchAnt Foundation, Rotterdam, Netherlands

#### **Background**

Today we witness the global health threat of antimicrobial resistance. This phenomenon relies largely on the erosion of the effective antimicrobials and has drawn the attention of researchers from the traditionally used antimicrobials to the so-called experimental compounds.

Experimental compounds are bioresearch compounds that have been subject to a certain degree of development, but have been put away either due to project deprioritization or lack of effectiveness against the application in question. They may, however, be very valuable in other applications; for instance, in diseases sharing similar biochemical pathways. These compounds are a rich source of new and, possibly, better antimicrobials. The question is: How can researchers gain access to them? We will discuss our efforts in developing a compound sharing facility and how we will collaborate with the community to facilitate open-innovation models for the antimicrobial compounds discovery.

#### **Objectives**

Our goal is to advance research in the field of antimicrobial resistance by re-purposing rare and one-of-the-kind experimental compounds to the whole of academic community. For that, we developed ResearchAnt Hub (RAH). RAH is powered by the ResearchAnt Foundation, which is a not-for-profit organization. RAH is a repository and a platform that fosters researchers worldwide to use and share their experimental compounds.

#### **Methods**

Our repository will contain thousands of experimental compounds that were developed or manufactured by privately- and academically-led researchers during the course of their work.

#### **Conclusions**

RAH is a unique not-for-profit open-innovation initiative. It represents a major step towards the discovery of new drugs to counteract today's ever-increasing antimicrobial resistance problem.

## **FEMS-1395**

### **New antimicrobials for resistant organisms**

#### **PSEUDOMONAS AERUGINOSA STRAINS PRODUCING ANTIMICROBIAL COMPOUNDS ISOLATED FROM HOSPITAL ENVIRONMENTS**

L.J. Reynolds<sup>1</sup>, S. Al<sup>2</sup>, S. Yu<sup>2</sup>, M. Muzslay<sup>2</sup>, P. Wilson<sup>2</sup>, M. Anjum<sup>3</sup>, A.P. Roberts<sup>1</sup>

<sup>1</sup>Microbial Diseases, UCL Eastman Dental Institute, London, United Kingdom

<sup>2</sup>Clinical Microbiology and Virology, UCLH NHS Foundation Trust, London, United Kingdom

<sup>3</sup>Department of Bacteriology, Animal and Plant Health Agency, London, United Kingdom

#### **Background**

Antibiotic resistant human pathogens are diminishing our ability to treat infections and novel antimicrobials are urgently needed to replace our current arsenal of antimicrobials. *Pseudomonas aeruginosa* strains have been shown to produce antimicrobial compounds including bacteriocins, pigments and secondary metabolites that show promise as novel antimicrobial therapeutic agents.

#### **Objectives**

To assess the antimicrobial activity of four environmental *P. aeruginosa* isolates from University College London, Hospital (UCLH).

#### **Methods**

Four *P. aeruginosa* isolates were obtained from various sites in UCLH. Cross streak assays using indicator organisms including *Escherichia coli*, *Staphylococcus aureus* and *Salmonella typhimurium* were conducted to determine the spectrum of inhibition of these *P. aeruginosa* strains. A spot-on lawn assay was used to compare the ability of each strain to inhibit the growth of *S. aureus*. To determine if the *P. aeruginosa* strains secreted compounds that were inhibiting *S. aureus*, this indicator strain was grown in cell free media that the *P. aeruginosa* strains were previously grown in.

#### **Conclusions**

Competitive hospital environments may be a rich source of bacteria producing novel antimicrobials. The results of the above experiments show that these four hospital environment acquired *P. aeruginosa* isolates are capable of inhibiting a wide range of bacteria. Some strains had a greater ability to inhibit *S. aureus* than others. All of the *P. aeruginosa* strains secreted inhibiting compounds into the media they were grown in. We are currently characterising the genetic and biochemical basis of these compounds.

**New antimicrobials for resistant organisms**

**EFFECT OF BACTERIOCIN PRODUCED BY STAPHYLOCOCCUS EPIDERMIDIS AGAINST MRSA**

*J. Kim<sup>1</sup>, J. Hong<sup>1</sup>, D. Lee<sup>1</sup>, J. Lim<sup>1</sup>, K. Jung<sup>1</sup>, S. Heu<sup>1</sup>, E. Roh<sup>1</sup>*

*<sup>1</sup>Microbial Safety Team, National Academy of Agricultural Science, Wanju-gun, Korea*

- Background: Staphylococcus aureus including methicillin-resistant S. aureus (MRSA) is recognized as a globally important pathogen in food-borne disease. Therefore bacteriocins have been focused on new weapon that are considered safe and effective substances as food additives to prevent food-borne pathogens.
- Objectives: To control MRSA of agricultural product, identify and characterize a antimicrobial peptide (bacteriocin) produced by Staphylococcus epidermidis.
- Methods: S. epidermidis were isolated from leafy green vegetables and identified by API Staph ID test and 16s rRNA sequence analysis. Antimicrobial activities of S. epidermidis against antibiotic resistant S. aureus and other Gram (+) bacteria were tested using agar diffusion assay. Purification of the active compound was achieved using a combination of ammonium sulfate precipitation, dialysis and reverse-phase high-performance liquid chromatography (RP-HPLC). The effects of heat, pH and enzymes on bacteriocin activity were determined using S. aureus CCARM3723 as indicator organism.
- Conclusions: S. epidermidis S-199 strain showed broad and strong antimicrobial activity. Purified antimicrobial peptide was heat-labile but stable in a wide range of pH. And the antimicrobial peptide showed resistance to  $\alpha$ -amylase, lipase, and RNase, and DNase. However, antimicrobial activity was lost after trypsin, pronase E, pepsin,  $\alpha$ -chymotrypsin, proteinase K, and papain treatment.

### **New antimicrobials for resistant organisms**

#### **ROLE OF PRODIGIOSIN AS A MICROBICIDE**

R. Suryawanshi<sup>1</sup>, C. Patil<sup>1</sup>, H. Borase<sup>1</sup>, G. Gonzalez<sup>2</sup>, S. Gonzalez<sup>2</sup>, D. Shukla<sup>3</sup>, S. Patil<sup>1</sup>

<sup>1</sup>*School of Ilfe Sciences, North Maharashtra University, Jalgaon, India*

<sup>2</sup>*Department of medicine, Centro de Investigaciones Biomedicas del Noreste, Monterrey, Mexico*

<sup>3</sup>*Department of Ophthalmology & Visual Sciences Microbiology & Immunology, College of Medicine University of Illinois at Chicago, Chicago, USA*

#### **Background**

Number of microbial species are metabolically wired to produce some pigments constitutively. Prodigiosin is such a pigment having prodigious biological activities in accord to its name. Microbicides are compounds that can be applied inside the vagina or rectum to protect against sexually transmitted infections (STIs). Discovery of drugs, targeting multiple steps in multiple diseases is of great interest.

#### **Objectives**

To evaluate prodigiosin for its microbicide potential and study its mechanism of actions in restricting sexually transmitted infections like *E. coli*, *C. albicans*, HSV, HIV, *Trichomonas vaginalis*. ii) To check cytotoxicity of prodigiosin against human cells.

#### **Methods**

96 well plate assay used for antibacterial assay followed by its biochemical investigations after treatment with prodigiosin at LC<sub>30</sub> concentration, cell associated and cell free assays were used to check anti HIV-1 (CXCR4 and CCR5) potential, while ONPG for HSV, cytotoxicity of prodigiosin was determined by MTT assay.

#### **Conclusions**

Prodigiosin induces leakage in bacterial cell membrane and simultaneously inhibits activity of few essential enzymes. Prodigiosin inhibits viral entry and cell fusion for HSV and HIV (IC<sub>50</sub>- 0.01 µg/ml). It also inhibited *T. vaginalis* (1.2 µg/ml). The use of pigment found on safer side against human cells (PBMC (78±3.1 µg/ml) and HeLa cells (70.2±5.3 µg/ml)). One compound having all these activities is a remarkable feature. Prodigiosin can be formulated as a microbicide (drug) and applied on the affected area with a cream base so as to treat the STIs. In conclusion prodigiosin can be used in treatment modality for protection from STIs.

**REGULATORY NETWORKS AND ECOLOGICAL CUES THAT CONTROL  
ANTIBIOTIC PRODUCTION BY ACTINOMYCETES**

G. van Wezel<sup>1</sup>, C. Wu<sup>1</sup>, Y.H. Cho<sup>2</sup>, J. Gubbens<sup>2</sup>

<sup>1</sup>*Molecular Biotechnology, Leiden University, LEIDEN, Netherlands*

<sup>2</sup>*Natural Product Laboratory, Leiden University, LEIDEN, Netherlands*

**Background**

Actinomycetes are prolific producers of natural products, including anticancer compounds, antifungals and antibiotics. The treasures that lie hidden in the actinomycete genomes may well be our final resource in the battle against the rapidly emerging infectious diseases associated with multi-drug resistance.

**Objectives**

We aim to understand the triggers and cues that elicit antibiotic production in the soil as well as in the laboratory. This knowledge is then translated into technologies for the activation and mining of silent pathways.

**Methods**

To uncover novel antimicrobials, we use a combination of ecological insights, systems biology, NMR-based metabolomics and genome mining to uncover the regulatory mechanisms that control antibiotic production. We then apply this for the discovery of novel antimicrobials.

**Conclusions**

One major control system revolves around the nutrient sensory protein DasR, which pleiotropically controls antibiotic production. Many other control systems are undoubtedly in place to allow actinomycetes to respond appropriately to challenges by competitors and fluctuations in nutrient composition in the habitat. Furthermore, once a bioactivity is elicited under specific growth conditions, novel approaches are needed to rapidly identify the bioactivity of interest and link it to a specific gene cluster. Molecular and ecological insights to elicit antibiotic production will be discussed, and examples of novel antibiotics identified by these approaches are presented.

## **ACTIVITY ANALYSIS OF LYSOSOMES AS A FUNCTIONAL CELL ORGANELLE IN *SACCHAROMYCES CEREVISIAE***

J. Yoon<sup>1</sup>, Y. Kim<sup>2</sup>, J. Min<sup>1</sup>

<sup>1</sup>Division of Chemical Engineering, Chonbuk National University, Jeonju, Korea

<sup>2</sup>Department of Microbiology, Chungbuk National University, Cheongju, Korea

### **Background**

Lysosomes are functional cell organelles which have antimicrobial and anticancerous activity. Lysosomal enzymes are easily integrated or released when exposed to some stimuli factors in all eukaryotic cells.

### **Objectives**

In order to verify features special function of lysosomes, several conditions were used to stimulate *in vitro* functions of lysosomes. In addition, we confirm lysosomal safety and activity *in vivo* for using antimicrobial and anticancerous materials.

### **Methods**

Proteomic analysis of lysosomal enzymes in response to the enhanced and repressed condition for *in vitro* activity using 2-DE. Among up-regulated protein dots response to oxidative stress, the dot with highest increase was chosen to overexpress in *Saccharomyces cerevisiae* and then confirm the lysosomal activity. In addition, we injected lysosomes into rat model infected with bacteremia, and then analysis bacterial growth in blood of rat according to the reaction time.

### **Conclusions**

The antimicrobial and anticancerous activity of lysosomes was enhanced in cloned *S. cerevisiae in vitro* assay. In addition, it is safe to inject lysosome into normal rat. Moreover, when being injected into rat model infected with bacteremia, lysosome showed its ability to inhibit bacterial growth in blood. Therefore, increases in endogenous levels of lysosomes may have various applications such as antimicrobial agents and apoptosis-inducing materials for cancer cells and it is very promising to use the organelles to improve *in vitro* and *in vivo* functions.

**New antimicrobials for resistant organisms**

**EFFECT OF ACID TREHALASE (ATH) ON IMPAIRED YEAST VACUOLAR ACTIVITY**

J. Yoon<sup>1</sup>, L.M. Tran<sup>1</sup>, Y. Kim<sup>2</sup>, J. Min<sup>1</sup>

<sup>1</sup>*Division of Chemical Engineering, Chonbuk National University, Jeonju, Korea*

<sup>2</sup>*Department of Microbiology, Chungbuk National University, Cheongju, Korea*

**Background**

Acid trehalase (ATH) has been suspected to have two different localizations, vacuolar lumen and cell surface, among which the localization at cell surface is believed to be responsible for extracellular trehalose utilization.

**Objectives**

A lot of efforts were made to confirm the exact localization of ATH in yeast cells. Along with this, the trafficking pathway responsible for the delivery of ATH into yeast vacuoles was also studied with the purpose to provide better control on the transportation of this protein in yeast cells.

**Methods**

ATH was overexpressed in yeast cells grown on trehalose-containing medium to observe the impact of this enzymes on yeast vacuolar activity. After that, 4 groups of typical proteins representing the 4 main trafficking pathways in yeast were also selected to analyze their expression pattern via 2DE.

**Conclusions**

The overexpression of ATH was observed to decrease vacuolar activity. Moreover, ATH was confirmed again to locate in both cell surface and vacuoles. Finally, it is interesting to discover that on medium containing trehalose, the ATH's localization at cell surface, but not vacuoles, is prioritized to utilize extracellular trehalose for cell growth. The mechanism behind that is suggested via the down regulation of MVB pathway that sorts ATH into vacuoles.

## **ANTIMICROBIAL AND ANTI-BIOFILM ACTIVITY OF SELENIUM AND TELLURIUM NANOPARTICLES OF BACTERIAL ORIGIN**

E. Zonaro<sup>1</sup>, S. Lampis<sup>1</sup>, R.J. Turner<sup>2</sup>, J.S. Qaz<sup>2</sup>, G. Vallini<sup>1</sup>

<sup>1</sup>Department of Biotechnology, University of Verona, Verona, Italy

<sup>2</sup>Department of Biological Sciences, University of Calgary, Calgary, Canada

### **Background**

In the last few decades, the emergence of bacterial resistance to antibiotics has become a common phenomenon. As a consequence, the effectiveness of antibiotic treatment of bacterial infection has progressively decreased. Therefore, it's necessary to develop and test new antimicrobial compounds against multidrug-resistant bacteria. Recently, the employment of metallic nanoparticles has emerged as an alternative to the use of organic compounds as antimicrobial agents: different metals and metalloids nanoparticles have indeed shown a promising bactericidal capability.

### **Objectives**

The aim of the present study was to evaluate the antimicrobial activity of selenium and tellurium nanoparticles of bacterial origin against both planktonic and biofilm culture of three pathogenic strains: *Escherichia coli* JM109, *Pseudomonas aeruginosa* PAO1 and *Staphylococcus aureus* ATCC 25923.

### **Methods**

To measure the antimicrobial activity of these nanoparticles we determined both the minimum biocidal concentration (MBC) and the minimum biofilm eradication concentration (MBEC) using the MBEC assay™. We also observed the effect of increasing concentrations of nanoparticles on biofilm structure using Confocal Microscopy (CLSM).

### **Conclusions**

Our results indicate that both Se<sup>0</sup> and Te<sup>0</sup> nanoparticles possess antimicrobial and biofilm eradication activity. In particular Se<sup>0</sup> nanoparticles exhibited antimicrobial activity at lower concentration. The activity seemed to be dependent on the dimension of the nanoparticles: indeed, the highest activity was shown by the nanoparticles smaller in size. The key observation is that bacteria grown in biofilm mode didn't exhibit a higher level of resistance against the nanoparticles antimicrobial action. Results described in this study suggest a possible application of these nanoparticles as an effective antimicrobial agent.

### **New approaches for typing**

#### **AN INTEGRATED PLATFORM FOR HIGH-THROUGHPUT WHOLE GENOME MLST AND WHOLE GENOME SNP ANALYSIS.**

S. De Graeve<sup>1</sup>, K. De Bruyne<sup>1</sup>, S. Valcke<sup>1</sup>, H. Pouseele<sup>1</sup>, K. Janssens<sup>2</sup>

<sup>1</sup>R&D, Applied Maths NV, Sint-Martens-Latem, Belgium

<sup>2</sup>CEO, Applied Maths NV, Sint-Martens-Latem, Belgium

### **Background**

With the increasing availability of next generation sequencing technology, whole genome sequencing (WGS) methods are increasingly being used for bacterial typing. Key challenge is the ability to rapidly extract the relevant information from large sequence data files.

### **Objectives**

We present two pipelines for high resolution WGS-based molecular typing: whole genome multilocus sequence typing (wgMLST) and whole genome single-nucleotide polymorphism analysis (wgSNP). Both strategies are compared using data from a *Staphylococcus aureus* outbreak.

### **Methods**

Using an in-house developed wgMLST schema that extends the core genome schema from Leopold *et al.* (2014), we apply two independent allele calling approaches, an assembly-free and a BLAST-based allele calling algorithm, to determine locus presence and detect allelic variants in a quality-controlled manner. The wgSNP pipeline, tuned to reduce false positives while maximizing resolution, detects SNP variants by mapping the WGS reads to a reference sequence internal or external to the data set.

For both methods, all calculation-intensive data processing steps are performed on the BioNumerics® Calculation Engine, deployed locally or in the cloud.

### **Conclusions**

The BioNumerics® 7.6 software and its integrated Calculation Engine offer a powerful platform where both wgMLST and wgSNP can be performed to provide a robust,

portable and high resolution picture of molecular typing data. The polyphasic approach allows for validation both between WGS analysis techniques and traditional techniques such as MLST or PFGE. We illustrate this by comparing core genome MLST (cgMLST), wgMLST and wgSNP, thus establishing a clear picture of the differences in resolution between those analysis techniques.

## **MOLECULAR INVERSION PROBES AND PYROSEQUENCING FOR SENSITIVE DETECTION OF MYCOBACTERIUM TUBERCULOSIS**

*R. Novais<sup>1</sup>, S. Borsuk<sup>2</sup>, O. Dellagostin<sup>2</sup>, Y. Thorstenson<sup>3</sup>*

<sup>1</sup>*Science, Rio de Janeiro State University, Sao Gonçalo, Brazil*

<sup>2</sup>*Biotechnology Center, Federal University of Pelotas, Pelotas, Brazil*

<sup>3</sup>*Stanford Genome Technology Center, Stanford University, Palo Alto, USA*

### **Background**

Tuberculosis is a treatable disease, yet remains a major worldwide health problem. In the last 10 years approximately 80 million people contracted the disease. The development of techniques for rapid diagnosis based in molecular technologies would greatly facilitate worldwide efforts to prevent further spread of the disease. One potential diagnostic sequence, the DR locus, is present in all isolates of *M. tuberculosis* complex bacteria. It is useful for molecular typing of *M. tuberculosis* because of its fortuitous absence in non-tuberculosis strains of mycobacteria.

### **Objectives**

In this study, we attempted to combine the specificity of molecular inversion probe (MIP) technology with the sensitivity of pyrosequencing in order to detect a short conserved 18 bp sequence included in DR locus in 25 isolates of *M. tuberculosis*.

### **Methods**

DNA from 25 *M. tuberculosis* isolates were extracted and submitted to the MIP reactions. A MIP was designed against the DR sequence of *M. tuberculosis* strain H37Rv and the MIP reactions were performed; the MIPs were then submitted to pyrosequencing reactions.

### **Conclusions**

We design a molecular inversion probe for a specific region of *M. tuberculosis* genome. Probing this MIP with 25 *M. tuberculosis* genomic DNA and determining their sequences by pyrosequencing, we detect a common sequence among all strains of *M. tuberculosis*. Also, we determine the minimal amount of DNA needed (50 ng) in order to obtain a good readout. By introducing a modification on pyrosequencing

methodology we were successful in detecting M.tuberculosis DNA even in presence of a very small amount of DNA (500fg).

**New approaches for typing**

**TYPING OF ENTEROBACTERIACEAE BY ERIC-PCR, REP-PCR AND MALDI-TOF MS METHODS**

S. Purkrtová<sup>1</sup>, A. Oliinyk<sup>1</sup>, E. Šviráková<sup>2</sup>, I. Němečková<sup>3</sup>, J. Pazlarová<sup>1</sup>, K. Demnerová<sup>1</sup>

<sup>1</sup>Department of Biochemistry and Microbiology,  
Faculty of Food and Biochemical Technology,  
University of Chemistry and Technology, Prague

<sup>2</sup>Department of Food Preservation, Faculty of Food and Biochemical Technology,  
University of Chemistry and Technology, Prague

<sup>3</sup>Department of Technology and Microbiology, Dairy Research Institute, Prague,  
Czech Republic

**Background:**The fast and reliable fingerprinting methods for typing of *Enterobacteriaceae* are widely required in food microbiology for tracking sources and ways of food contamination. ERIC-PCR and REP-PCR genotyping use as markers specific DNA sequences (enterobacterial repetitive intergenic consensus sequences or repetitive extragenic palindromic sequences, respectively) and the changes of their dispersal, detectable by methods. In comparison MALDI-TOF MS phenotyping uses the conformity of protein profiles. As used typing markers mirror the differences among strains only partially, also compared to other features as the antibiotics resistance and biofilm formation, their combination could propose more precise approach.

**Objectives:**The aim was to compare the discriminatory power of ERIC-PCR, REP-PCR and MALDI-TOF MS fingerprinting methods for different *Enterobacteriaceae* isolates, also with respect to their antibiotics resistance and biofilm formation.

**Methods:**Fifty six isolates of *Enterobacteriaceae*, including genera *Escherichia*, *Enterobacter*, *Klebsiella*, *Serratia* and *Raoultella*, isolated from food and clinical sources in Czech Republic in 2007-2014, were genotyped by the same ERIC-PCR and REP-PCR methods (maximal length of analysed fragments 3000 bp). MALDI-TOF MS typing was done by the ethanol-formic acid extraction in Bruker Autoflex Speed MALDI-TOF mass spectrometer. The resistance for 12 antibiotics and the ability to form biofilm in different media at 25 °C were tested.

**Conclusions:** REP-PCR is more discriminative than ERIC-PCR in most species. The discriminatory power of MALDI-TOF MS phenotyping depends on the range of used protein peaks (e.g. application of specific intensity criteria) and the used clustering methods, but never gives the false positive results in comparison to the genotyping methods.

**FEMS-0688**

**New approaches for typing**

**USE OF MATRIX-ASSISTED LASER DESORPTION/IONIZATION- TIME OF FLIGHT (MALDI-TOF) MASS SPECTROMETRY FOR ROUTINE ANALYSIS IN A DRINKING WATER TREATMENT PLANT**

L. Sala-Comorera<sup>1</sup>, C. García-Aljaro<sup>1</sup>, C. Vilaró<sup>2</sup>, B. Galofré<sup>2</sup>, A.R. Blanch<sup>1</sup>

<sup>1</sup>*Microbiology, University of Barcelona, Barcelona, Spain*

<sup>2</sup>*Microbiology, Aigües de Barcelona EMGCIA, Barcelona, Spain*

**Background**

Drinking water treatment plants employ different treatments depending on source water quality to assure adequate chemical and microbiological quality according to the Directive 98/83/EC. The study of bacterial communities throughout the treatment plant could provide a basic understanding of the effects of water processing that can be used to improve the management in drinking water treatment plants.

**Objectives**

To assess the use of MALDI-TOF MS for routine analysis in a drinking water treatment plant to study bacterial diversity throughout the different treatments in comparison with other methods such as the PhenePlate® system, the API 20E strip and 16S rRNA gene sequencing.

**Methods**

A total of 366 colonies isolated from different points and seasons throughout the water treatment process including feed water (40), sand filtration (36), ultrafiltration (44) and reverse osmosis (191) were used in the study. The colonies were analyzed by MALDI-TOF MS by direct colony inoculation on the plate. The colonies were also biochemically fingerprinted using the PhenePlate® system, clustered according to their similarity and a representative strain was selected for 16S rRNA gene sequencing and API based identification.

**Conclusions**

The diversity decreased along the different treatments, with a total of 20 genera being detected. The use of MALDI-TOF MS was reliable compared to the PhenePlate® system and has the advantage of being faster and relatively cheap compared to other technologies such as the 16S rRNA sequencing. The API web was not sufficiently reliable for water monitoring since the identification of the majority of the strains failed compared to the other methods used.

**MOLECULAR DIVERSITY OF CANDIDA ALBICANS ISOLATED FROM IMMUNOCOMPROMISED PATIENTS, BASED ON MLST METHOD**

M.H. Afsarian<sup>1</sup>, T. Shokohi<sup>1</sup>, H. Badali<sup>1</sup>, S. Najafipour<sup>2</sup>

<sup>1</sup>Department of Mycology and Parasitology / Invasive Fungi Research Center, Mazandaran University of Medical Sciences, Sari, Iran

<sup>2</sup>Department of Microbiology, Fasa University of Medical Sciences, Fasa, Iran

**Background**

Multilocus sequence typing (MLST) is used as a highly discriminatory method for tracing sources and routes of transmission, and the genetic relatedness of isolates.

**Objectives**

The aim of the study was to assess the genetic diversity among *C. albicans* strains isolated from oropharynx and bronchoalveolar lavage (BAL) of immunocompromised patients.

**Methods**

A total of fourteen epidemiologically unrelated clinical isolates of *C. albicans* from three hospitals in northern Iran were tested. Seven loci of housekeeping genes were sequenced for all fourteen isolates.

**Conclusions**

The fourteen isolates were placed in 10 clonal clusters (CC) while two isolates were singletons, by eBURST analysis. Most of the isolates were belong to CC461 of eBURST analysis from the clade 11 and two isolates assigned to CC172 from the clade 15.

In conclusion, Genetic diversity is variable among unrelated strains obtained from different patients at different times and places, and epidemiologically unrelated strains usually are not genetically closely related and classify in different clusters

**MULTILOCUS SEQUENCE TYPING STRAINS OF YERSINIA  
PSEUDOTUBERCULOSIS ISOLATED IN RUSSIA**

*N. Timchenko<sup>1</sup>, S. Ermolaeva<sup>2</sup>, E. Psareva<sup>1</sup>, R. Adgamov<sup>2</sup>, K. Sobyenin<sup>2</sup>*

*<sup>1</sup>Russian Academy of Medical Sciences,*

*Institute of Epidemiology and Microbiology of G.P. Somov Siberian Branch,  
Vladivostok, Russia*

*<sup>2</sup>Russian Academy of Medical Sciences,*

*Institute of Epidemiology and Microbiology of NF. Gamaleya, Moscow, Russia*

Background: The epidemic spread of a special clinical and epidemiological form of pseudotuberculosis, Far East Scarlet-Like Fever (FESLF) was firstly described in Russia (Far East, Vladivostok) in the late 1950s [1].

Objective: To characterize *Yersinia pseudotuberculosis* strains isolated in Russia (Far East, Siberia, Europe) in 1973-2014 years with the multilocus sequence typing (MLST) method to ascertain a position of the strains in a phylogenetic structure of the species.

Methods. Totally, 80 *Y. pseudotuberculosis* strains isolated from the stool of patients with clinical signs of FESLF (n=54), vegetables (n=11) and rodents (n=15) were included in the study. The MLST method developed by Achtman et al. (<http://www2.warwick.ac.uk/mlst>) was used. The MLST scheme is based on 7 house-keeping genes.

Conclusion. The majority of *Y. pseudotuberculosis* strains isolated from patients belonged to sequence type ST2 (85.2%, serotype 01b). Five and three clinical strains belonged to ST26 (9.3 %, serotype 01b) and ST32 (5.5%, serotype 03), respectively. *Y. pseudotuberculosis* serotype 01b strains isolated from vegetables belonged to ST2 (81.8%) and ST14 (18.2%). Strains isolated from rodents (01b serotype) belonged to ST2 (60%), ST42 (20%), ST64 (13,3%), ST32 (6,7%). Serotype O3 rodent isolates belonged to ST14 (5.3%). MLST results showed the *Y. pseudotuberculosis* ST2 serotype 01b clone prevails in Russia among all studied sources including patients, vegetables, and rodents.

**PHENOTYPIC AND GENOTYPIC IDENTIFICATION OF SALMONELLA USING ANTISENSE PEPTIDE NUCLEIC ACID PROBE - MULTITYPING.**

O. Adebawale<sup>1</sup>, K. Chindera<sup>1</sup>, S. Goh<sup>1</sup>, L. Good<sup>1</sup>

<sup>1</sup>PPB, Royal Veterinary College, London, United Kingdom

**Background**

Development of novel strategies for rapid and specific identification of bacteria pathogens is urgently needed to aid successful medical and epidemiological interventions in disease outbreaks.

**Objectives**

In this study we evaluated the feasibility of altering growth phenotypes by silencing specific essential genes with antisense probes as a rapid bacterial diagnostic tool.

**Methods**

Salmonella Typhimurium and *Escherichia coli* strains were treated with antisense Peptide Nucleic Acid (PNA) probe targeting *Salmonella ftsZ* at concentrations 0-3.0µM. Cultures were grown in non-selective Muller Hinton broth (MHB), selective Rappaport-Vassiliadis Soya Peptone (RVS), and modified Rappaport-Vassiliadis Soya Peptone-low salt (mRVSS) and cell morphologies were examined by microscopy.

**Results**

If *ftsZ* silencing is successful, cells are expected to elongate, and we here observed that treatment with the Salmonella anti-ftsZ PNA treatment elongated Salmonella grown in MHB and modified RVS low salt (mRVSS), but not in RVS. In contrast, *E. coli* did not elongate when treated under the same conditions. Likewise, untreated *Salmonella cells* did not elongate. Also, modified RVS low salt media retained Salmonella selectivity and enrichment qualities.

**Conclusions**

Anti-ftsZ PNA treatment can provide both phenotypic and genotypic identification of Salmonella, and the method can be combined with selective growth conditions. We are further testing this method using artificially contaminated water and milk.

## FEMS-2611

### New diagnostic approaches

#### DEVELOPMENT OF A QPCR TO DETECT PSEUDOMONAS AERUGINOSA IN CULTURE-NEGATIVE SAMPLES FROM CYSTIC FIBROSIS PATIENTS AND MONITOR THE EFFECTIVENESS OF ANTIBIOTIC TREATMENT

M. Amiri<sup>1</sup>, S. Pasquaroli<sup>1</sup>, G. Mangiaterra<sup>1</sup>, N. Cirilli<sup>2</sup>, E. Manso<sup>3</sup>, B. Citterio<sup>4</sup>, F. Biavasco<sup>1</sup>

<sup>1</sup>Department of Life and Environmental Sciences, Polytechnic University of Marche, Ancona, Italy

<sup>2</sup>Cystic Fibrosis Center, Salesi Children's Hospital, Ancona, Italy

<sup>3</sup>Biochemical and Microbiology Laboratory, Ospedali Riuniti, Ancona, Italy

<sup>4</sup>Department of Biomolecular Sciences sect. Toxicological Hygiene and Environmental Sciences, University of Urbino Carlo Bo, Urbino, Italy

### Background

Early detection of *Pseudomonas aeruginosa* in cystic fibrosis (CF) samples is pivotal for disease eradication by antibiotic treatment. However, standard cultural methods are hampered by slow growth and alginate overproduction of mucoid variants, and possibly by viable but non-culturable state induction.

### Objectives

This work aimed at developing a qPCR for improved *P. aeruginosa* infection diagnosis in sputum from CF patients and assessment of the effectiveness of antibiotic treatment.

### Methods

Thirty-three sputum samples that were negative by culture assays were collected from 28 CF patients. DNA was extracted by the QIAamp DNA kit after centrifugation to remove free DNA. Real-time PCR assays targeting the species-specific gene *ecfX* were performed.

### Conclusions

Six/33 samples were positive for *P. aeruginosa* by qualitative Real-time PCR (LOD: 60 cells/ml) and were analyzed by qPCR (LOQ:  $3 \times 10^2$  cells/ml). *P. aeruginosa* abundance exceeded the LOQ in three samples, which carried  $1 \times 10^3$ ,  $1.6 \times 10^4$  and  $2.8 \times 10^6$  cells/ml, respectively. Three successive samples from a culture-negative, symptomatic patient, showed bacterial counts <LOQ (May 7);  $1 \times 10^3$  (still culture-negative but now receiving inhaled antibiotic therapy; May 11), and <LOQ (at the end

of antibiotic therapy; May 28). Four months later the patient was positive by cultural assays.

The matching qPCR and clinical results highlight the value of molecular assays in *P. aeruginosa* detection and quantification in CF. Dead cells cannot account for the whole difference found between PCR and culture data. Dormant forms in the pulmonary biofilm, coupled with the greater sensitivity of PCR, are likely to account for a large part of this difference.

**FEMS-2133**

**New diagnostic approaches**

**AMPEROMETRIC DETECTION OF B-LACTAMASE ACTIVITY AND ITS APPLICATION TO THE IDENTIFICATION OF EXTENDED SPECTRUM B-LACTAMASE PRODUCING STRAINS IN BLOOD SAMPLES**

*L. Betelli<sup>1</sup>, C. Neuwirth<sup>2</sup>, A. Hartmann<sup>3</sup>, S. Solanas<sup>1</sup>, J. Claire<sup>3</sup>, M. Dequaire Rochelet<sup>1</sup>*

<sup>1</sup>UMR Agroécologie 1347, Université de Bourgogne, Dijon, France

<sup>2</sup>Laboratoire de Bactériologie, CHU Dijon, Dijon, France

<sup>3</sup>UMR Agroécologie 1347, INRA, Dijon, France

**Background**

With the ever-expanding role of extended-spectrum  $\beta$ -lactamase (ESBL) -harboring *Enterobacteraceae* in causing serious infections, rapid diagnostic assays of such resistant organisms are highly desired to improve patient screening and hospital infection control practices as well as to reduce inappropriate antibiotic use.

**Objectives**

To reach this goal, we developed an amperometric detection of the  $\beta$ -lactamase activity in blood culture samples using disposable carbon screen-printed sensors in the presence of a well-chosen cephalosporin substrate.

**Methods**

Using an ESBL enzyme isolated from a clinical strain, we showed that the intensity of a specific anodic peak current resulting from the catalytic hydrolysis of the  $\beta$ -lactam ring was proportional to the amount of ESBL. A novel susceptibility assay for the rapid and specific identification of ESBL-producing bacteria in blood culture samples was then proposed. This assay was based on a two-step protocol performed within 2 hours : (1) subculturing of blood culture samples in the presence or absence of cefotaxime and/or the potassium clavulanate (ESBL inhibitor) for a few hours followed by, (2) incubation of the subculture filtrates with the redox substrate which hydrolysis was monitored by amperometry. This assay allowed the reliable and specific identification of various types of  $\beta$ -lactamases-producing bacterial species (including ESBLs, penicillinases, cephalosporinases) in blood cultures.

**Conclusions**

Owing to its low cost, portability, simplicity and its ability to perform measurements in turbid media, the electrochemical approach, which did not require prior strain isolation, holds great promise for the rapid screening of  $\beta$ -lactamases in clinical and other complex samples.

FEMS-2135

New diagnostic approaches

## RAPID AMPEROMETRIC DETECTION OF ESCHERICHIA COLI IN WASTEWATER BY MEASURING B-D GLUCURONIDASE ACTIVITY WITH DISPOSABLE CARBON SENSORS

*M. Dequaire Rochelet<sup>1</sup>, S. Solanas<sup>1</sup>, F. Vienney<sup>1</sup>, A. Hartmann<sup>2</sup>*

<sup>1</sup>UMR Agroécologie 1347, Université de Bourgogne, Dijon, France

<sup>2</sup>UMR Agroécologie 1347, INRA, Dijon, France

### Background

Methods based on the direct measurement of  $\beta$ -D-glucuronidase (GLUase) activity in the presence of the 4-methylumbelliferyl- $\beta$ -D-glucuronide substrate are well-established to specifically monitor *Escherichia coli* (*E.coli*) in water samples without any cultivation step. However, because of the interferences from auto-fluorescence or light-quenching particle in complex samples, the fluorescence detection is often not suitable for the analysis of environmental samples.

### Objectives

To overcome this drawback, the amperometric quantification of GLUase activity was investigated and applied to the rapid and specific detection of *E. coli* in wastewater samples.

### Methods

For this purpose, the *p*-aminophenyl  $\beta$ -D-glucopyranoside (PAPG) was selected as electrochemical substrate for GLUase measurement and the *p*-aminophenol (PAP) released during the enzymatic hydrolysis was monitored by cyclic voltammetry with disposable carbon screen-printed sensors. The intensity of the measured anodic peak current was proportional to the amount of GLUase, thus providing a measurement of the number of *E.coli* in the sample (using a calibration curve).

Following an optimized protocol, we were able to detect *E. coli* cells in the range of  $5 \times 10^4$  to  $10^8$  per filter within 2 h. The amperometric assay was applied to the determination of fecal contamination in raw and treated wastewater samples and it successfully compared with conventional bacterial plating methods and *uidA* gene detection by quantitative PCR.

### Conclusions

Owing to its ability to perform cell density measurements in turbid media, the GLUase amperometric method is a reliable tool for the rapid and decentralized quantification of viable but also non-culturable *E.coli* in complex environmental samples.

### **New diagnostic approaches**

#### **RAPID DETECTION OF SALMONELLA SPP. USING AN ISOTHERMAL AMPLIFICATION BASED SYSTEM, DNABLE**

V. Dutta<sup>1</sup>, T. Guerrette<sup>1</sup>, L. Peters<sup>1</sup>, B. Parker<sup>1</sup>

<sup>1</sup>Pathogens and Veterinary Science, EnviroLogix Inc., Portland, USA

#### **Background**

The rapid, cost-effective, and robust detection of pathogens continues to be a major focus for the livestock industry. While PCR has filled the niche for a highly sensitive detection, PCR inherently burdens the end user with cumbersome sample preparation, complex and closed instrumentation with long time-to-result (TTR) (1.5-3h post-enrichment, excluding sample preparation). Other DNA amplification methods have shortened the TTR but have not been able to provide a robust and reliable alternative to PCR. The need for improved testing solutions continues to grow with growing intricacies of production logistics.

#### **Objectives**

Here we present an isothermal DNA amplification tool called DNABLE for *Salmonella* spp. detection. This system provides a distinctive advantage over other technologies as it combines high specificity and sensitivity with minimal sample preparation leading to a significantly reduced TTR (30-40 min post-enrichment, including sample preparation).

#### **Methods**

*Salmonella* detection was demonstrated with an analytical sensitivity of <50cp of genomic DNA per reaction or <10 cells post-enrichment in multiple test matrices. Inclusivity and exclusivity data indicate 100% accuracy across 34 *Salmonella* serotypes and 29 non-*Salmonella* tested strains.

#### **Conclusions**

DNABLE requires minimal sample preparation due to its robust chemistry and is compatible with a range of detection equipments. *Salmonella* spp. detection system also includes an internal amplification control, *Salmonella* selective media supplement that improves current enrichment, and a user-friendly sample preparation kit. Results are provided by a portable and simple DNABLE reader or user provided thermocycler. The inherent robustness, quick TTR, and broad range instrument compatibility support use of DNABLE for *Salmonella* detection.

**FABRICATION OF DNA ELECTROCHEMICAL BIOSENSOR BASED ON CARBON NANOTUBES FOR DETECTION OF FECAL CONTAMINATED WATER WITH ENTEROCOCCUS FAECALIS**

A.O. El-Gendy<sup>1</sup>, H.A.M. Hendawy<sup>2</sup>, A.M. Ibrahim<sup>2</sup>

<sup>1</sup>Microbiology and Immunology Department, Faculty of Pharmacy Beni-Suef university, Beni-Suef, Egypt

<sup>2</sup>Analytical Chemistry Department, National Organization for Drug Control and Research (NODCAR), Cairo, Egypt

**Background**

Fecal pollution of water can lead to health problems due to presence of infectious microorganisms especially *Enterococcus faecalis* (*E. faecalis*) which may be derived from human sewage or animal sources. Hence, detection of these microorganisms is of much interest using different methods. Electrochemical DNA biosensors, which employ an immobilized DNA as the biological recognition element, are currently under intense investigation in detection of several microorganisms relying on the conversion of the base-pair recognition event into a useful electrical signal.

**Objectives**

The aim of this study was to demonstrate a rapid and inexpensive method for accurately detection of *E. faecalis* in contaminated water via fabrication of a specific and selective DNA electrochemical biosensor.

**Methods**

A modified DNA oligonucleotide with 5' amino modifier C12 was designed based on a house keeping gene glucose 6-phosphate dehydrogenase of *E. faecalis*. The multi walled carbon nanotubes (MWCNT) were allowed to form amide bond between their carboxylic acid groups and amino groups of oligonucleotides. Hybridization was performed by incubating the DNA/self-assembled MWNTs with complementary DNA oligonucleotides, non-complementary DNA oligonucleotides, genomic DNA and artificial contaminated water under specific conditions for 30 min at room temperature. The hybrid-electrodes were successively transferred into hybridization indicator of methylene blue for 30 min without any potential followed by several washings and subsequently electrochemical measurements.

**Conclusions**

Such single-use electrochemical biosensors have great promise for decentralized water testing for presence of *E. faecalis* in an accurate and rapid approach.

University Clinic of Respiratory and Allergic Diseases Golnik, Golnik, Slovenia

<sup>2</sup>Department of Biotechnology and Systems Biology, National Institute of Biology, Ljubljana, Slovenia

<sup>3</sup>Molecular and Cell Biology, LGC, London, United Kingdom

### **Background**

Acute exacerbations of chronic obstructive pulmonary disease (AE COPD) are predominantly caused by microbial pathogens. Molecular techniques may improve the speed and sensitivity of respiratory infections diagnostics. Currently there is limited knowledge on the best method for DNA extraction from sputum samples.

### **Objectives**

This study is a part of the European JRP HLT08 INFECT-MET. The aim was to evaluate the DNA yield of two different extraction methods, manual and automated, in treated and untreated sputum samples from COPD patients.

### **Methods**

A total of 47 good-quality sputum samples from COPD patients between March 2014 and October 2014 were included in the study. Twenty samples were left untreated and 27 were treated with NALC-NaOH. All samples were split in two aliquotes and DNA was extracted with manual (QIAamp DNA Mini Kit, Qiagen GmbH, Germany) and automated (DNA Extraction Kit, DiaSorin, Italy/NorDiag Arrow) method. Concentration of DNA was quantified (Qubit Fluorometer, Invitrogen, USA).

### **Conclusions**

Out of 47 sputum samples 41 (87,2%) had higher DNA concentration with automated extraction method. Among 20 untreated sputum samples automated method had a higher DNA yield in 14 samples by 68,1%, lower in 5 by 43,1 % and equal in 1 sample. In 27 treated sputum samples automated extraction method had a higher DNA yield in all 27 samples by 60,9%.

Automated extraction method proved to be more efficient in extracting DNA from untreated and treated sputum samples. Automated extraction method is much easier to perform and less time consuming.

**New diagnostic approaches**

## **DEVELOPMENT OF DUAL-FUNCTION ELISA FOR EFFECTIVE ANTIGEN AND ANTIBODY DETECTION AGAINST H7 AVIAN INFLUENZA VIRUS**

F. He<sup>1</sup>, J. Kwang<sup>1</sup>

<sup>1</sup>*Animal Health Biotechnology, Temasek Life Sciences Laboratory, Singapore, Singapore*

### **Background**

Outbreaks in poultry involving influenza virus from H7 subtype have resulted in human infections, thus causing a major concern for public health, as well as for the poultry industry. Currently, no efficient rapid test is available for large-scale detection of either antigen or antibody of H7 avian influenza viruses.

### **Objectives**

In the present study, a dual function ELISA was developed for the effective detection of antigen and antibody against H7 AIVs.

### **Methods**

The test was established based on antigen-capture-ELISA and epitope blocking ELISA. The two Mabs 62 and 98 which were exploited in the assay were identified to recognize two conformational neutralizing epitopes on H7 HA1. Both of the epitopes exist in all of the human H7 strains, including the recent H7N9 strain from China and > 96.6% of avian H7 strains. The dual ELISA was able to detect all of the five H7 antigens tested without any cross reaction to other influenza subtypes. The antigen detection limit was less than 1 HA unit of H7. For antibody detection, the sensitivity and specificity of the dual ELISA was evaluated and compared to HI and microneutralization using immunized animal sera to different H7 strains and different subtypes of AIVs. Results indicated that antibodies to H7 were readily detected in immunized animal sera by the dual ELISA whereas specimens with antibodies to other AIVs yielded negative results.

### **Conclusions**

This is the first dual-function ELISA reported for either antigen or antibody detection against H7 AIVs. The assay was highly sensitive and 100% specific in both functions rendering it effective for H7 diagnosis.

<sup>2</sup>Microbiology, Istanbul University Institute of Forensic Sciences, ISTANBUL, Turkey

<sup>3</sup>Microbiology, Istanbul University Cerrahpasa Medical Faculty, ISTANBUL, Turkey

<sup>4</sup>Microbiology, Public Health Institution of Turkey, ISTANBUL, Turkey

<sup>5</sup>Microbiology, Turkish Red Crescent, ISTANBUL, Turkey

#### Background

HIV-1/2 testing algorithms are currently controversial. The most important problem and difficulty about this debate is undeterminate HIV-1 infections (UHIV-1). Studies for an optimised algorithm for UHIV-1 are under research.

#### Objectives

In this study, we aimed to determine neopterin and sCD-14 levels in cases with UHIV-1 and confirmed HIV-1 (CHIV-1) infections and evaluate the relationship between UHIV-1 and real HIV-1 infection and also aimed to evaluate the diagnostic values of two markers, especially in situations when PCR were not available and western blot were undeterminate after ELISA.

#### Methods

Eighty-eight cases with UHIV-1, 100 patients with CHIV-1 and 100 healthy control group (HCG) were included. Neopterin and sCD-14 levels were determined by competitive and sandwich ELISA (nmol/mL, µg/mL, quantitatively) methods, respectively. Statistical tests were performed using SPSS 21.0 and  $p < 0.05$  was considered significant.

#### Conclusions

##### Results:

Table 1. Neopterin and sCD-14 levels of UHIV-1 and CHIV-1 cases and healthy control group

Markers (n:100)	Undeterminate HIV-1 <sup>1</sup> (n:88) HCG <sup>3</sup> (n:100)	Confirmed-HIV-1 <sup>2</sup>
--------------------	---	------------------------------

Neopterin, mean (min-max)	5.73 (1.58-38.71)	15.77 (1.19-127.19)	7.95 (3.16-41.08)
sCD14, mean (min-max)	3.65 (1.86-6.17)	4.20 (1.53-7.59)	3.51 (0.97-3.97)

P value: Neopterin: 1x2; p:0.004, 1x3; p:0.754

sCD14: 1x2; p:0.034, 1x3; p:0.787

Table 2. Diagnostic test performances of neopterin and sCD14 in CHIV-1 infections

Markers	Sensitivity	Specificity	PPV	NPV	Kappa coefficient
Neopterin (%)	38	82	76	57	20
sCD14 (%)	50	100	100	67	50

As conclusion,, we couldn't suggest UHIV-1 pattern as real HIV-1 infection and we concluded that two markers were useless as surrogate markers for real HIV-1 infections.

<sup>5</sup>Microbiology, Istanbul University Institute of Experimental Medicine Cerrahpasa Medical Faculty, ISTANBUL, Turkey

<sup>6</sup>Primary care, Erenköy Psychiatric hospital, ISTANBUL, Turkey

#### Background

Isolated Anti-HBc pattern (IAH) positivity causes diagnostic difficulty in laboratory diagnosis of HBV infections. In addition, this pattern is a big problem for clinical diagnosis and blood transfusion.

#### Objectives

In this study, we aimed to determine neopterin and sCD-14 levels in cases with IAH and chronic active hepatitis (CAH) and to evaluate the relationship between IAH and real HBV infection and also aimed to evaluate the diagnostic values of two less sophisticated and cheaper surrogate markers in situations when the molecular methods were not available.

#### Methods

IAH (n:102), KAH (n:70) and healthy control group (HCG), (n:100) cases were included in the study. Neopterin and sCD-14 levels were determined by competitive and sandwich ELISA (nmol/mL, µg/mL, quantitatively) methods, respectively. Statistical tests were performed using SPSS 21.0 and p < 0.05 was considered significant.

#### Conclusions

Table 1. Neopterin and sCD-14 levels in IAH, KAH and HCG cases .

Markers	IAH <sup>1</sup>	KAH <sup>2</sup>	HCG <sup>3</sup>

	(n:102)	(n:70)	(n:100)
Neopterin, mean (min-max) (3.16-41.08)	8.67 (3.56-67.15)	15.43 (4.75-43.27)	7.95
sCD14, mean (min-max) (0.97-3.97)	3.61 (1.82-6.17)	4.20 (1.96-6.78)	3.51

p value: Neopterin: 1x2; p:0.002, 1x3; p:0.915

sCD14 : 1x2; p:0.006, 1x3; p:0.821

Table 2. Diagnostic test performances of neopterin and sCD14 in real HBV infections

Markers coefficient	Sensitivity	Specificity	PPV	NPV	Kappa
Neopterin (%)	59	82	69	75	42
sCD14 (%)	51	90	78	73	44

As conclusion, we couldn't suggest IAH pattern as a real HBV infection and we concluded that two markers were useless as surrogate markers for the diagnosis of HBV infections.

**DETECTION OF THE OOMYCETE PYTHIUM INSIDIOSUM BY REAL-TIME PCR OF THE EXO-1,3-B-GLUCANASE GENE**

T. Krajaeju<sup>1</sup>, A. Keeratijarut<sup>1</sup>, T. Lowhnoo<sup>2</sup>, W. Yingyong<sup>2</sup>, T. Rujirawat<sup>2</sup>,  
C. Srichunrusami<sup>1</sup>, P. Onpeaw<sup>1</sup>, P. Choungtrakool<sup>1</sup>

<sup>1</sup>Pathology, Faculty of Medicine Ramathibodi Hospital Mahidol University, Bangkok, Thailand

<sup>2</sup>Research center, Faculty of Medicine Ramathibodi Hospital Mahidol University, Bangkok, Thailand

**Background**

Pythiosis is a life-threatening infectious disease caused by the pathogenic oomycete *Pythium insidiosum*. The disease has high rates of morbidity and mortality. Timely diagnosis permits prompt treatment and a better prognosis. *PinsEXO1*, encoding an exo-1,3- $\beta$ -glucanase, is a novel and efficient target for identification of *P. insidiosum* by conventional PCR.

**Objectives**

In this study, we aimed to develop a real-time PCR approach targeting *PinsEXO1* and compare its performance to conventional PCR for the detection of *P. insidiosum*.

**Methods**

Genomic DNA samples were prepared from 35 culture-proven *P. insidiosum* isolates and 58 culture-proven fungi (served as the control), for PCR analyses. Both conventional and real-time PCR assays were positive for all *P. insidiosum* strains tested, while all control fungi were negative. Turnaround time for conventional PCR was 4 hr, while that of real-time PCR was 1.5 hr. The minimum DNA template required for successful PCR amplification by conventional and real-time PCR were 1 ng and  $1 \times 10^{-4}$  ng, respectively.

**Conclusions**

The real-time assay retained high detection sensitivity and specificity. It showed a substantially improved analytical sensitivity and turnaround time that could improve diagnoses of pythiosis.

**FEMS-2304**

**New diagnostic approaches**

**DEVELOPMENT OF A NOVEL MALARIA ANTIBODY ASSAY UTILIZING ANTIGENS FROM ALL 5 HUMAN PATHOGENIC PLASMODIUM SPECIES**

A. Latz<sup>1</sup>

<sup>1</sup>R+D, NovaTec Immundiagnostica GmbH, Dietzenbach, Germany

**Background**

The proper diagnosis of Malaria disease is essential to provide early treatment and improve the prognosis of patients. Transfusion-transmitted Malaria is rare, but it may produce severe problems in the safety of blood Transfusion and blood related products due to the lack of reliable procedure to evaluate donors potentially exposed to malaria.

**Objectives**

Microscopy, still considered the gold standard for diagnosing malaria. It is time consuming and requires trained expertise. ELISAs are known to be ideal for high throughput screening with high sensitivity and specificity, but it also requires trained personal and an equipped laboratory. Line Blots are often used as confirmatory tests since they provide high sensitivity and specificity. There is nearly no lab equipment needed to perform this kind of assay. In addition, blots can also be used in automated processes for high throughput screening.

**Methods**

Here we show an improved diagnostic performance of the new antibody detection Systems (ELISA and Lineblot) utilizing early and late antigens of all 5 human pathogenic Plasmodium species (*P. falciparum*, *P. vivax*, *P. ovale*, *P. malariae*, *P. knowlesi*) compared to test systems only relying on antigens derived from one or two Plasmodium species. Assays with a limited number of antigens often fail to detect antibodies from certain regions of the world. For evaluation purpose, we collected samples from all over the world, including samples from newborns.

**Conclusions**

We evaluated the performance of ELISA and Lineblot directly in endemic countries with samples of patients who presented symptoms akin to malaria infection in local hospitals.

**INVESTIGATION OF ORTHOPAEDIC IMPLANT ASSOCIATED INFECTIONS:  
ALTERNATIVE APPROACHES TO LABORATORY PROCESSING AND CULTURE**

A. Lual<sup>1</sup>, R. Siddiqui<sup>1</sup>,

*. UK Standards for Microbiology Investigations Working Group for Clinical Bacteriolog*

*y*<sup>1</sup>

<sup>1</sup>*Standards Unit, Public Health England, London, United Kingdom*

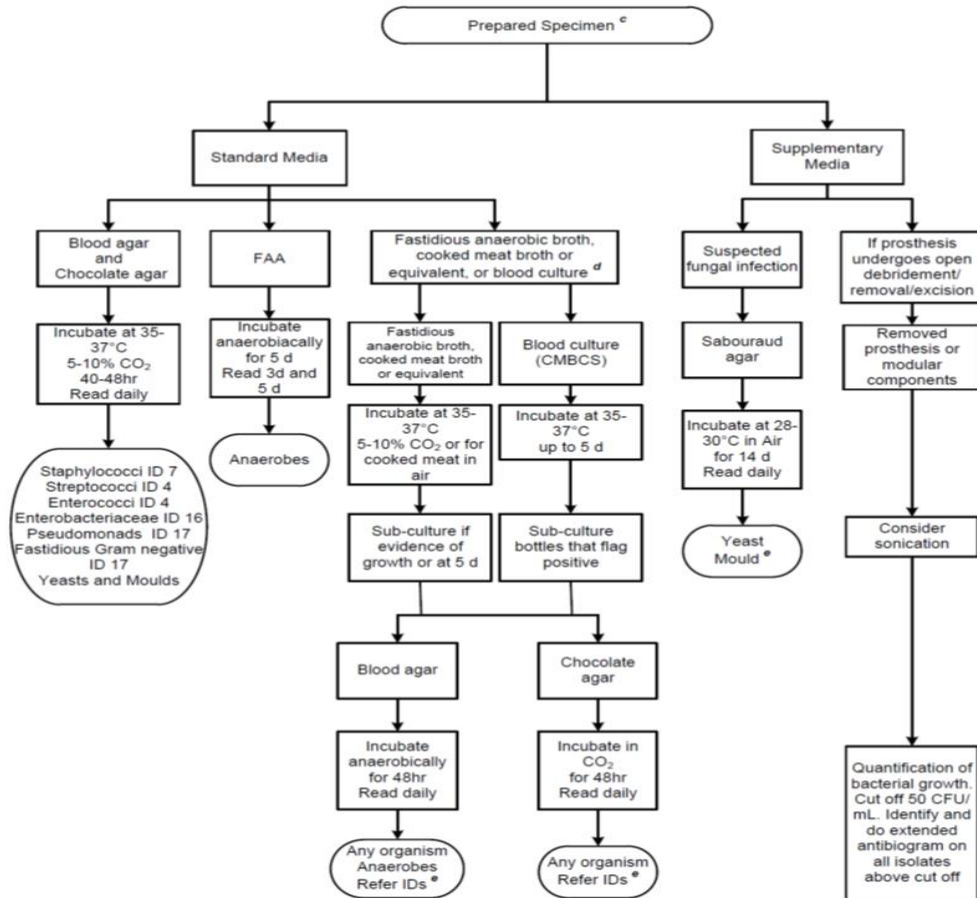

**Background**

Since its introduction in the 1960s, joint replacement (arthroplasty) has become a common procedure. Around 15% of revisions are due to 'septic' loosening caused by biofilm formation on the implant. Infection rates are now much lower; however, there is still a risk associated with each procedure. UK SMI B44: is a diagnostic tool aimed at practising professionals in the field of microbiology. It describes and recommends methods for the microbiological investigation of orthopaedic implant associated infection.

**Objectives**

The aim of this poster is raise awareness of the various methods of sample preparation (including the use of glass beads and sonication) and culture. Timely diagnosis and treatment can help reduce the likelihood of systemic dissemination of infection. Therefore, in most cases, this UK SMI recommends up to 5 days culture using either cooked meat broth or continuous monitoring blood culture system

methods.

## Methods

Produced by the Standards Unit, UK SMIs are developed, reviewed and updated through a wide consultation process with users and other stakeholders. The process follows the AGREE tool and resulting documents reflect best evidence based practice. Where evidence is not available, the documents are based on national working group consensus decisions.

## Conclusions

B44 provides guidance on the best minimum practice when investigating orthopaedic implant associated infection. It is a useful resource for laboratories which aims to help drive pathology modernization by recommending alternative technologies for timely laboratory diagnosis of infection.

<sup>2</sup>Department of Infectious Diseases, Sahlgrenska Academy at the University of Gothenburg, Gothenburg, Sweden

<sup>3</sup>Department of Mathematical Sciences, Chalmers University of Technology, Gothenburg, Sweden

<sup>4</sup>Department of Infectious Diseases, Sahlgrenska Academy of the University of Gothenburg, Gothenburg, Sweden

<sup>5</sup>Department of Analytical Chemistry, Nanoxis Consulting AB, Gothenburg, Sweden

### Background

Diagnosing infectious diseases requires a range of methodologies for the comprehensive detection, characterisation and identification of infectious bacteria. Proteomics-based approaches represent an alternative to traditional methods of characterising microorganisms, elucidating expressed biomarkers of genome information, applied to 'proteotyping' microorganisms at all taxonomic levels.

### Objectives

Apply state-of-the-art and novel techniques of tandem mass spectrometry (MS) analyses of expressed proteins for species- and strain-level identification and detection of antibiotic resistance and virulence, with the focus on optimizing MS-based proteomics analyses for 'proteotyping' infectious bacteria.

### Methods

Intact bacteria or cell fractions were immobilised, via membrane-gold interactions within a flow-cell. Within the flow-cell, proteins were subjected to enzymatic digestion to generate peptides, which were identified, using LC-MS/MS. Following database matching, peptides were used for bacterial species-level identification, and for detection of antibiotic resistance and sub-species typing. To demonstrate proteotyping capability and differentiate closely related species, mixtures of different *Streptococcus* spp. were analysed. Results of *Streptococcus* spp. identifications from clinical samples were confirmed by standard microbiology, including cultivation of bacteria in selective media, PCR, DNA sequencing and MALDI-TOF MS analyses.

### Conclusions

Proteotyping of infectious bacteria, using LC-MS/MS enabled the differentiation and identification of *Streptococcus* spp. by ranking identified expressed proteins, according to the number of peptide matches to genome sequence information available in databases, and was applied to detection in clinical samples. The methods

have been shown to enable reproducible, sensitive, rapid and cost-effective typing of bacteria for diagnostics of infectious diseases.

<sup>4</sup>HIV LABORATORY,

INSTITUTO DE DIAGNOSTICO Y REFERENCIA EPIDEMIOLOGICOS,  
MEXICO D.F., Mexico

#### **Background**

Western Blot (WB) is the gold standard as HIV-1 confirmatory test, which has high cost and complexity in processing, our setting send the reactive samples to a national reference center for confirmation and reporting of results takes at least 15 days.

#### **Objectives**

The aim of this work was to standardize a technique multiplex PCR as a complementary test for the detection and confirmation of HIV-1 infection in Oaxaca, Mexico.

#### **Methods**

Standardization of the multiplex PCR was perform using primers designed to amplify the *gag*, *pol* and *env* genes of M, N, O groups and other specific to Subtype B. For the standardization, we use DNA of three patients that was previously characterized as HIV positive and samples sequenced for HIV-1 (*pol*, *gag*, *env*). We used this multiplex PCR in DNA samples from PMBC of 600 patients. All patients were screening by HIV rapid test. To confirm HIV infection, both WB and multiplex PCR were perform.

#### **Conclusions**

We obtain concordant results with multiplex PCR and those of WB. The implementation of a multiplex PCR as a supplemental test for confirmation of HIV-1 infection is reliable and safe. Its implementation has the possibility of decreasing the time of detection and reporting of confirmatory results to a day, which is essential, for example, in cases of pregnant women the confirmation or discard of HIV must be timely, with the aim to start prophylaxis on time.

<sup>2</sup>*Centro VISAVET, Universidad Complutense de Madrid, Madrid, Spain*

**Background**

Although direct smear technique is an excellent approach for the preparation of samples for MALDI-TOF MS identification, the usefulness of this approach is limited to BSL-1/BSL-2 bacteria, it is not recommended for MSP creation and it requires fresh material for an optimal performance. Formic acid extraction is proposed as a more precise method for MALDI Biotyper identification that includes a step in which bacteria are suspended in 70% ethanol which could potentially be used for the storage of bacterial suspensions in their optimal growth phase. However, there is a lack of information regarding the impact of storage of bacterial suspensions in ethanol on the the reliability of the MALDI-Biotyper identification.

**Objectives**

A study was carried out aiming to assess the influence of time (90 days) and temperature (room temperature and 4°C) on the identification by MALDI Biotyper.

**Methods**

Two bacterial suspensions (*E. coli* and *S. aureus*) stored in ethanol 70% were included. Half of the aliquots (n=27) were conserved at room temperature and the other half at refrigeration until the day of analysis (0, 5, 8, 12, 19, 26, 42, 71 and 90 days).

**Conclusions**

Our data suggest that *E. coli* and *S. aureus* ethanol suspensions can be stored up to 90 days for MALDI Biotyper identification in laboratory conditions. Although it has to be validated, it may apply to other bacteria and could greatly facilitate laboratory work-flow and shipment of bacterial suspensions

<sup>3</sup>Unit of Helicobacter Pathogenicity Department of Microbiology, Institute Pasteur, Paris, France

<sup>4</sup>Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy

**Background**

To elucidate the molecular mechanisms involved in persistency/latency of the *H.pylori* infection or in its progression towards serious diseases, it is necessary to analyze the host pathogen interaction in vivo. The circulating antibody repertoire represents an important source of diagnostic information, serving as biomarker to provide a 'disease signature'.

**Objectives**

The aim of this work is the identification of *H.pylori* epitopes responsible for host immunoresponse modulation through a discovery-driven approach that couples 'phage display' and deep sequencing.

**Methods**

We used an approach for identifying novel antigens by screening gDNA libraries created from the pathogen genome, directly with sera from infected patients. Three phage display libraries from three *H.pylori* strains (HP26695, HPB128, HPSS1) have been constructed by using  $\beta$ -lactamase ORF selection vectors (Di Niro et al., 2010). Genomic DNA was sonicated, fragments cloned into the filtering vector, after transformation libraries of  $1 \times 10^6$  clones were obtained and sequenced by 454 technology.

**Conclusions**

More than 93% of HP CDSs were represented in the phage genomic library therefore being representative of the whole *H.pylori* antigenic ORFeome. Putative antigens were selected from libraries using sera from patients affected by *H. pylori* presenting increasing degrees of infection: i) autoimmune gastritis and pernicious anemia; ii) gastric adenocarcinoma; iii) MALT lymphoma. The results show that the diversity of the libraries obtained after selection is significantly reduced. Furthermore, individual ranks, for each infection condition, have been compared highlighting the pattern of putative antigens, shared by all the conditions, and some that can distinguish the different stages of infection.

**New diagnostic approaches**

**DETECTION OF CRYPTOSPORIDIUM OOCYST RNA BY SURFACTANT EXTRACTION TREATMENT AND RT-PCR: INHIBITION OF REVERSE TRANSCRIPTION BY SDS AND ITS SUPPRESSION USING NONIONIC SURFACTANTS**

T. Sekikawa<sup>1</sup>, K. Toshiki<sup>1</sup>

<sup>1</sup>Graduate Division of Nutritional and Environmental Sciences, University of Shizuoka, Shizuoka, Japan

**Background**

*Cryptosporidium* causes the symptoms of cryptosporidiosis including watery diarrhea, vomiting and fever. *Cryptosporidium* oocysts possess a robust wall, which is extremely resistant to chlorine used for potable water disinfection. Successful DNA detection from the robust oocyst usually requires complicated procedures including DNA extraction such as freeze-thaw cycling and enzyme treatment. Therefore, we previously developed a surfactant extraction treatment (SET) method for extracting DNA from the oocysts with only sodium dodecyl sulfate (SDS).

**Objectives**

We examined the inhibition of reverse transcription-PCR (RT-PCR) by SDS and its suppression using four kinds of nonionic surfactants in order to develop a new method for detecting 18S rRNA from the oocyst by SET and RT-PCR.

**Methods**

The template DNA/RNA was amplified in the presence of SDS and/or the nonionic surfactants; Tween 20, Tween 80, Triton X-100, Triton X-114 by RT-PCR to evaluate the inhibition of reverse transcriptase and DNA polymerase. The oocysts were incubated in a 0.1% SDS solution to extract DNA/RNA.

**Conclusions**

DNA/RNA amplification was inhibited at 0.01% SDS but its inhibition was suppressed by adding any of the nonionic surfactants at 5%. There was a difference in the suppression efficacy of the nonionic surfactants in tests that used 0.1% SDS. 18S rRNA molecules are present in high copy numbers in viable cells, which increases detection sensitivity. Therefore, we succeeded to detect 18S rRNA equivalent to 10<sup>-4</sup> oocysts by SET and RT-PCR. This work was supported in part by JSPS KAKENHI Grant Number 25420559 and the Kurita Water and Environment Foundation.

**Background**

Quick and proper wound diagnostics could avoid wound infections of currently 5-10% of post-surgical - and 25% of chronic wound patients. Apart from standard methods, this study focusses on the wound fluid, harboring enzymes of the human immune system and reflecting a critical wound status upon increasing activity.

**Objectives**

The determination of the enzyme levels of the neutrophil derived enzymes human neutrophil elastase (HNE), myeloperoxidase (MPO) and lysozyme (LYS) was assessed and correlated to the bacterial burden of the wounds [1]. New diagnostic approaches were based on these enzymes and include electrochemical and optical sensor systems for fast diagnosis of infections in chronic wounds [2].

**Methods**

The enzyme activities of HNE, LYS and MPO were directly monitored in wound fluid of affected patients via biochemical investigations. Both electrochemical sensors such as measuring the hydrogen peroxide consumption by MPO as current decrease and lateral flow devices based on release of dyes were developed.

**Conclusions**

Determination of the enzyme activities showed more than 6 to 10 fold higher substrate conversion in infected wound fluids when compared to non-infected wound fluids and clearly correlated with the elevated bacterial burden (Fig1). Consequently, both the electrochemical sensor as well as lateral flow devices were able to differentiate between infected and non-infected wounds.

<sup>4</sup>., Regional Laboratory of Public Health, Haarlem, Netherlands

#### Background

As a commensal of the upper respiratory tract, *Streptococcus pneumoniae* is a potential pathogen causing respiratory and invasive diseases. Following implementation of pneumococcal conjugate vaccination (PCV) for infants, surveillance studies have proven essential for monitoring direct (carriage of serotypes targeted by vaccine, VTs) and indirect effects (changes in carriage of non-vaccine serotypes, NVTs).

#### Objectives

To compare the detection of pneumococcal carriage and serotypes in a unique study setting using both conventional culture and molecular methods, in nasopharyngeal samples from healthy PCV-vaccinated infants in two large, cross-sectional surveillance studies on PCV-effects in the Netherlands.

#### Methods

Nasopharyngeal samples were collected from 1182 11- and 24-month old children (n=591 each) during autumn/winter 2010/11 (n=584) and 2012/2013 (n=598). Following conventional culture on plates selective for *S. pneumoniae*, DNA extracted from all bacterial growth was tested by quantitative-PCR (qPCR) for the presence of pneumococci and a panel of serotypes, including serotypes targeted by the thirteen-valent PCV (PCV13).

#### Conclusions

There was a correlation (Spearman's rho=0.980;  $p<0.001$ ) between the frequency of serotypes detected using qPCR and prevalence according to conventional culture. Moreover, we observed a trend ( $p=0.056$ ) for an underestimation of carriage detection for serotypes not targeted by PCV7 or PCV10 (in use in the Netherlands) compared to PCV10-serotypes when detected using the culture-method alone. We found no evidence of a hidden circulation of serotypes rarely detected by culture or those targeted by vaccination. This suggests that surveillances based on the culture method alone do not underestimate carriage of VTs in immunised children.

**Background**

In the field of natural product research, finding new sources of bioactive compounds is of primary importance. In this respect, microorganisms have provided a large number of biologically active molecules.

**Objectives**

Recently, the use of fungal co-cultures for the induction of new natural products has emerged as a promising field in drug discovery.

For the success of such studies, a key element is the development of a co-culture methodology that provides high reproducibility of metabolite induction patterns and that is compatible with high throughput analytical procedures.

**Methods**

To tackle this issue, a method based on 12-well-plate miniaturized Petri dishes compatible with high throughput UHPLC-TOF-MS metabolomics [3] has been developed. This strategy was used to screen for metabolite induction in co-cultures of various fungal species. This approach provided a satisfactory reproducibility and was used for the identification of induced biomarkers.

**Conclusions**

This study demonstrates the consistent induction of new metabolites through co-culture. Moreover, the developed strategy is generic and can be applied to other types of microorganisms that can grow on solid media and that are part of the myco- or microbiome. This 12 well-plate approach and the adapted data mining strategy were validated by the untargeted metabolomic study of a model co-culture (*Eutypa lata* versus *Botryosphaeria obtusa* responsible for confrontation zone lines in *Vitis* wood). This procedure is currently used for screening novel metabolite induction in various fungal co-cultures.

### **Background**

Cyclodipeptide synthases (CDPSs) constitute a novel family of enzymes that use charged tRNAs to synthesize cyclodipeptides in biosynthetic pathways dedicated to the synthesis of diketopiperazines, a large class of secondary metabolites with noteworthy biological activities. To date, 11 CDPSs have been biochemically characterized, showing the incorporation of hydrophobic amino acids in cyclodipeptides (essentially Phe, Leu, Tyr and Trp). Biochemical and structural characterizations of three CDPSs identified catalytic residues and allowed to propose a ping-pong mechanism for cyclodipeptide formation. However, bioinformatic searches in databases identified in microbial genomes numerous putative CDPS whose activities are not predictable. Furthermore, some of these CDPSs showed differences in predicted catalytic residues.

### **Objectives**

Our objective was to provide a better characterization of the CDPS family of enzymes notably by determining the cyclodipeptide-synthesizing activity of a large set of unrelated putative CDPSs identified in databases.

### **Methods**

We used bioinformatic tools to select the CDPS candidates for biochemical characterization and to analyze their amino acid sequences. As previous work showed the recovery of cyclodipeptides in culture supernatants upon CDPS expression in *Escherichia coli*, CDPSs were produced in this host and cyclodipeptides were searched in culture supernatants by HPLC coupled to mass spectrometry.

### **Conclusions**

The determination of the activities of 41 novel CDPSs enlarged the chemical diversity synthesized by these enzymes, as they were shown to incorporate 17 of the 20 proteinogenic amino acids. CDPSs can be classified into several phylogenetically distinct subfamilies characterized by specific functional subsequence signatures, suggesting differences in catalysis by members of the two subfamilies.

<sup>3</sup>*Biochemistry and Molecular Biology, Faculty of Biology University of Belgrade, Belgrade, Serbia*

### **Background**

*Bacillus* cyclic lipopeptides of surfactin, iturin, fengycin, and recently discovered kurstakin families have well-recognized potential in biotechnology and biopharmacies. Analytical method such as matrix-assisted laser desorption ionization-time of flight mass (MALDI-TOF) spectrometry proved very effective for detection and identification of various antimicrobial substances.

### **Objectives**

The present study was aimed at investigating how different mode of extraction of crude lipopeptides produced by different *Bacillus* strains influence the amount of crude lipopeptide and highlights the best extraction mode for further use.

### **Methods**

Five proven lipopeptide producers were grown under previously determined conditions and consequently extracts were obtained by ethyl acetate extraction and by combination of acid precipitation and methanol extraction. Also, cell-free supernatants in the form of aqueous extracts were examined. Extracts were subjected to MALDI-TOF-MS analysis in the acquisition mass range 800-1700 Da.

### **Conclusions**

Mass spectra obtained from all extracts tested, showed clearly three peak clusters corresponding to different lipopeptide families. Cluster of peaks, corresponding to iturin and surfactin families, with similar intensities and points to the dominant presence of these compounds in all strains and extracts, was observed. However, for peaks within the mass range of 1450-1540, corresponding to fengycin family, the best detection was achieved for ethyl acetate extracts. The peaks in the mass range of kurstakin family, for most cases, were more pronounced in the aqueous extract, while the lowest detection was obtained for methanolic extraction. In conclusion, the most efficient was ethyl acetate extraction, which gives the most prominent peaks together with the aqueous extract as a positive control.

<sup>3</sup>*Division of Gastroenterology and Hepatology, Medical University of Graz, Graz, Austria*

### **Background**

Antibiotic-associated hemorrhagic colitis (AAHC) develops during antibiotic-driven intestinal dysbiosis and is caused by production of the bacterial pyrrolobenzodiazepine tilivalline.

### **Objectives**

To understand the function of this secondary metabolite during health and disease we study the regulation of tilivalline biosynthesis and degradation.

### **Methods**

Genes involved in tilivalline biosynthesis were identified via transposon mutagenesis of the clinical isolate AHC-6. Genes encoding a 3-deoxy-D-arabino-heptulosonate-7-phosphate (DAHP) synthase (*aroX*), a dehydroquinate-synthase (*aroB*) and two non-ribosomal peptide synthases (*npsA* and *npsB*) were identified as essential genes for tilivalline production. Adjacent genes *npsA*, *npsB* and *aroX* are located on a pathogenicity island present in all toxin positive *Klebsiella* isolates.

Under laboratory conditions tilivalline is detected in conditioned medium of bacterial cultures. Cytotoxicity towards human epithelial HeLa cells appears at the end of the exponential phase (8 h), reaches a maximum during stationary phase and decreases after 40 h to undetectable levels at 48 h. The loss of cytotoxicity can indicate a growth-dependent regulation of biosynthesis and/or inactivation of tilivalline. Emergence of degradation products in tilivalline-depleted supernatant was analyzed by HPLC-MS and NMR. Regulation of tilivalline biosynthesis genes in vitro was monitored via qRT-PCR.

### **Conclusions**

We find that transcription of *npsA* and *npsB* is regulated in a growth dependent

manner. Current studies focus on effects of host and microbial factors on tilivalline biosynthesis and cytotoxicity.

<sup>2</sup>LIFL UMR CNRS 8020 Université Lille 1- Sciences et Technologies, Inria-Lille Nord Europe, villeneuve d'ascq, France

<sup>3</sup>Laboratory of Phytopathology, Faculty of Bioscience Engineering, Ghent, Belgium

**Background**

Many of natural compounds produced by microorganisms, are synthesized by non ribosomal peptides synthetases (NRPS), working as assembly lines. Among them, lipopeptides as those produced by *Bacillus* and *Pseudomonas*, may play an important role in sustainable agriculture, used as biopesticides to kill plant pathogens.

**Objectives**

As lipopeptides are synthesized by NRPS, we have decided to screen and identify *in silico* all NRPS gene clusters of *burkholderia*, especially those producing siderophores and lipopeptides, potentially implicated in biocontrol of phytopathogens.

**Methods**

We performed *in silico* detection and analyses of NRPS genes present in 48 gapless complete genomes of *Burkholderia* available in the NCBI, by following Florine, a workflow we have developed especially with this aim.

**Conclusions**

Genome analyses revealed 161 clusters containing NRPSs, with the potential to synthesize at least 11 novel products. Although most strains produce the main siderophore ornibactin or malleobactin, a cluster corresponding to a new siderophore, called phymabactin, was identified in *Burkholderia phymatum* STM815 and the cluster for cepaciachelin biosynthesis was, for the first time, identified in *Burkholderia ambifaria* AMMD. Elsewhere, the cluster for the antifungal burkholdin was detected in both the genomes of *B. ambifaria* AMMD and *Burkholderia* sp. KJ006. We also

identified a novel lipopeptide called burkhomycin specifically produced by *Burkholderia pseudomallei* strains. This study revealed the significance of the genus *Burkholderia* as a promising source of bioactive compounds. It also gave new insights on the non-ribosomal synthesis exemplified by the identification of dual C/E domains in lipopeptide NRPSs, as frequently found in *Pseudomonas* strains.

<sup>1</sup>LGBM, CEA-IG UMR8030 CEA/UEVE/CNRS, Evry Cedex, France

**Background**

Trigonelline (N-methylnicotinate), a pyridine alkaloid, is produced by plants to resist draught stress. Its catabolism by soil bacteria is presumed to proceed through methylamine and succinate but no pathway is described until now.

**Objectives**

Our model organism is *Acinetobacter baylyi* ADP1, a strictly aerobic, nutritionally versatile soil bacterium which is easily amenable to genetic manipulations. Biological tools and ressources have been developed in the laboratory to enable the integrative analysis of its metabolism. Since it grows well on trigonelline, we wanted to elucidate this pathway at the finest level.

**Methods**

By comparative genomics, we could identify a conserved cluster of 10 genes involved in trigonelline breakdown. We dissected the pathway by combining bacterial physiology with mutant strains, classical enzymology with recombinant enzymes and untargeted LC/MS based metabolomic approaches.

**Conclusions**

In reaction mixtures with trigonelline, we could detect succinate semialdehyde and succinate along with three new metabolites, which were produced on a preparative scale, purified and structurally characterized by 1D- and 2-D NMR. Unexpectedly, the first intermediate exhibited a rare 5-hydroxy-butyrolactone structure in equilibrium with an open form, which resulted from a successive reduction-oxidation and cleavage of the pyridine ring followed by a recyclization. This reaction scheme remains unprecedented for a natural pyridine compound and may have valuable spin-off effects in the field of bioremediation since pesticide derivatives or pyridine itself may also be catabolized by this way.

In addition, we showed that trigonelline metabolism is connected with the metabolism of compatible solutes in the cell, extending its physiological function in bacteria beyond nutrition.

#### **MICROBIAL VOLATILES – SMALL COMPOUNDS WITH POWERFUL ACTIVITIES**

*P. Garbeva<sup>1</sup>, R. Schmidt<sup>1</sup>, K. Schulz<sup>1</sup>, O. Tyc<sup>1</sup>*

*<sup>1</sup>Microbial Ecology, NIOO-KNAW, Wageningen, Netherlands*

#### **Background**

Soil microorganisms produce a range of secondary metabolites like antibiotics, toxins, biosurfactants, siderophores. Beside these metabolites soil microorganisms are capable of emitting another class of secondary metabolites so called volatile organic compounds (VOCs). Volatiles are low molecular mass compounds (100-300 Da) with high vapor pressures, low boiling points and lipophilic character. These properties facilitate evaporation and diffusion through both water- and gas-filled pores in soil and rhizosphere environments. As compare to other microbial secondary metabolites volatiles are relatively less studied.

#### **Objectives**

The major aim of our study was to obtain more insight in the role of volatiles in microbial interactions.

#### **Methods**

In order to obtain insight in the importance of volatiles in the inter-specific interactions between soil microorganisms we performed several experiments in glass Petri dishes plates, which were designed as such that growth of different microorganisms occurred in physically separated areas within a common atmosphere. In this way we studied the role of volatiles in fungal-bacterial and bacterial-bacterial interactions. The volatiles were analysed by using thermal desorption GSMS.

#### **Conclusions**

The obtained results revealed that volatiles play important role in the interaction between soil microorganisms. Here we will report on bacterial volatiles with (1) antimicrobial activity and (2) on volatiles acting as infochemicals affecting the behavior, growth and gene expression in responding bacteria. Furthermore we will report on the effect of fungal volatiles on bacteria and on the importance of interspecific interactions for the production of volatile.

## **ANALYSIS OF THE DRAFT WHOLE GENOME SEQUENCE OF THE HUMIDIMYCIN PRODUCER STREPTOMYCES HUMIDUS F-100.629**

O. Genilloud<sup>1</sup>, M. Sánchez<sup>1</sup>, J. Pascual<sup>1</sup>

<sup>1</sup>Microbiology, Fundación MEDINA, Granada, Spain

### **Background**

Characterization of new secondary metabolite biosynthetic clusters is gaining increased attention because of their potential to produce new molecules with medical and biotechnological application. Most biosynthetic pathways in actinobacteria are cryptic or silenced in standard laboratory conditions, requiring alternative approaches to identify and these new clusters.

Humidimycin (MDN-0010) is a peptide structurally related to the antiviral siamycins that potentiates the antifungal activity of caspofungin against *Aspergillus fumigatus* and *Candida albicans* (1). Humidimycin is produced by the strain *Streptomyces humidus* F-100.629.

### **Objectives**

This study has been focused on a gene mining of *S. humidus* F-100.629 to identify the humidimycin biosynthetic pathway and other potential cryptic biosynthetic gene clusters.

### **Methods**

Whole genome sequence was obtained with Illumina. Assembly and annotation were performed using standard bioinformatics tools.

### **Conclusions**

The draft genome size of *S. humidus* F-100.629 was estimated in 8.4 Mb. The biosynthetic cluster of humidimycin was identified and 50 putative secondary metabolite clusters were predicted using the antiSMASH application (2), including PKS-I, PKS-II, NRPS, terpenes, siderophores and bacteriocin, suggesting the genomic potential of the strain as producer of diverse natural products.

## **MICROEVOLUTION OF THE BIOACTIVE PEPTIDE ANABAENOPEPTIN IN CYANOBACTERIA**

E. Holzweber<sup>1</sup>, G. Christiansen<sup>1</sup>, J.F. Blom<sup>2</sup>, J. Pernthaler<sup>2</sup>, R. Kurmayer<sup>1</sup>

<sup>1</sup>University of Innsbruck, Research Institute for Limnology, Mondsee, Austria

<sup>2</sup>University of Zürich, Institute of Plant Biology, Kilchberg, Switzerland

### **Background**

Bloom-forming cyanobacteria such as the genus *Planktothrix* sp. form a large number of bioactive peptides, e.g. the family of the Anabaenopeptins (AP) through nonribosomal peptide synthesis (NRPS).

### **Objectives**

In total 140 *Planktothrix* strains, isolated from various climatic zones, were phylogenetically assigned into three major lineages that differed in ecosystem type colonization. We analyzed the distribution and recombinations of the AP synthesis gene cluster (*apn*).

### **Methods**

The presence or absence of the *apn* gene cluster was determined by polymerase chain reaction (PCR) and sequencing of PCR products.

### **Conclusions**

We found that the majority of strains of lineage 1, occurring in shallow lakes, carried specific *apn* remnants in parallel to the full gene cluster. The recombinations occurred within adenylation domains resulting in rare structural variants as well as a fusion of part of the ABC transporter domain from another NRPS gene cluster. In contrast, strains of lineage 2, isolated from deep lakes, did not contain *apn* remnants but always contained the full gene cluster. Strains of lineage 3, isolated from tropical regions, did not carry any sequence related to *apn*. Overall evolutionary diversification of *apn* genes was congruent with ecological diversification. Because of the occurrence of *apn* remnants and recombination events within the *apn* in lineage 1 we hypothesize that its ancestor lost the *apn* genes but some of the genotypes regained it through horizontal transfer.

**A NEW GENE CLUSTER FOR MYCOSPORINE-LIKE AMINO ACID BIOSYNTHESIS IN CYANOBACTERIUM: HETEROLOGOUS EXPRESSION, PURIFICATION, AND CHARACTERIZATION**

M. KATOCH<sup>1</sup>, R. Mazmouz<sup>1</sup>, R. Chau<sup>1</sup>, N. Brett<sup>1</sup>

<sup>1</sup>Microbiology and Molecular Diversity,  
School of Biotechnology and Biomolecular Sciences University of New South Wales  
Sydney Australia, Sydney, Australia

**Background**

Mycosporine-like Amino Acids (MAAs) are an important class of secondary metabolites known for their protection against ultra violet (UV) radiation and other cellular functions, such as scavenging of free oxygen radicals, regulation of osmotic balance, and resistance to thermal and salt stress and desiccation. Cyanobacteria are microorganisms that colonize diverse ecological niches exposed to the UV light and produce MAAs. Because of its efficient sunscreen role, the MAA shinorine from cyanobacteria is utilized commercially in sunscreen creams.

**Objectives**

The biosynthesis of MAA was recently solved and showed that the structural diversity is directly encoded by the gene cluster. Bioinformatic analysis of the genome of the soil strain *Cylindrospermum stagnale* revealed a new gene cluster homolog to the MAAs biosynthetic gene cluster. Analysis of this gene cluster presents five genes instead of three/four common biosynthetic genes in other cyanobacteria.

**Methods**

The gene cluster was successfully cloned and heterologously expressed in *E. coli*. The MAA was extracted from recombinant *E.coli* cultures and identified through HPLC and a UV absorption maxima of 310 nm. Structural characterization is underway, combining the data from mass spectrometry and NMR.

**Conclusions**

The characterization of MAA gene cluster from *Cylindrospermum stagnale* shows a new gene organization suggesting that it codes for a novel biosynthesis pathway. The new MAA, potentially produced by this terrestrial strain, might play a role for combating the terrestrial environmental stress(s).

Korea Research Institute of Bioscience & Biotechnology (KRIBB), Daejeon, Korea*

<sup>3</sup>*Sustainable Bioresource Research Center,  
Korea Research Institute of Bioscience & Biotechnology (KRIBB), Daejeon, Korea*

### **Background**

Phycocyanin (PC) is the major pigment of the phycobiliproteins in cyanobacteria. The commercial applications of PC could be divided into two sections; the first is an ingredient for nutrient elements, natural dyes for food and cosmetics, and the second is a potential remedy in oxidative stress-induced diseases.

### **Objectives**

The aim of this study was to increase the PC content in the isolated cyanobacterium (*Nostoc* sp.) with nitrogen-free medium and chromatic acclimation.

### **Methods**

*Nostoc* sp. was cultured for 10 days in 1-L cylinder flasks containing 800 ml nitrogen-free BG11 medium. For chromatic acclimation, two types of light sources were compared, i.e. plant-fluorescent lamp (only blue and red wavelengths are provided) and white fluorescent lamp.

### **Conclusions**

Under fluorescent lamp condition, the maximum biomass production was 2.24 g DCW/L (dry cell weight g/L). High biomass production could be achieved by nitrogen fixation of *Nostoc* sp., even without nitrogen supply. The maximum biomass concentration was higher at 2.65 g DCW/L under plant lamp condition. It means that blue and red lights in plant lamp are more critical in promoting cell growth. Cell color also changed from brown to green through chromatic acclimation by plant lamp. Higher PC content (15%) in cells was obtained and maintained throughout the cultivation. By changing light source from white to plant lamp, biomass production and PC content have been increased. Cost-effective PC production was possible,

due to its nitrogen fixation ability. More simplified PC extraction process was also devised for more efficient PC production.

<sup>3</sup>Post-graduate Program in Chemistry, Amazonas Federal University, Manaus, Brazil

<sup>4</sup>Faculty of Agricultural Sciences, Amazonas Federal University, Manaus, Brazil

### **Background**

The endophytic microorganisms (EM) of the Amazon are potential producers of secondary metabolites with biological activity that can be used on infected wounds.

### **Objectives**

This research investigated the antibiotic action of ME from the Amazon front of pathogenic microorganisms present in the in wound healing process.

FIG 01.

FIG 02.

### Methods

The antibiotic activity of 171 secondary metabolites of endophytic microorganisms (MSME) were analyzed against *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *Escherichia coli* and *Candida albicans* by diffusion in agar. In the test were used 50 $\mu$ L of each MSME extract; ampicillin, tetracycline, ciprofloxacin and fluconazole, all in 2% as positive control according to the test microorganism and DMSO as a negative control. The readings of the zones inhibition were carried out in 24 and 48 hours. The mean, standard deviation, ANOVA and Tukey's test ( $p < 0.05$ ) were performed for analysis.

### Conclusions

The largest zone of inhibition with significant differences for *C. albicans* were MSME DfGa2 1.2 G4 ( $2.88 \pm 0,71\text{cm}$ ) and DfGa2 1.2 G5 ( $2.72 \pm 0,69\text{cm}$ ), for *S. aureus* were MSME DfGa2 1.2 G4 ( $2,52 \pm 0,83\text{cm}$ ) and DfGa2 1.2 G5 ( $2,32 \pm 0,45\text{cm}$ ), for *P. aeruginosa* were MSME DfGa2 1.2 G5 ( $2,24 \pm 0,30\text{cm}$ ). For *E. coli* there was no significant difference between the means of the zones of inhibition. The authors concluded that the samples DfGa 2 1.2 G4 and DfGa 2 1.2 G5 had better antibiotic action for the tested pathogens, suggesting a formulation of a gel and, subsequently, its evaluation *in vivo* of the activity of healing wounds in rats.

**ANTIFUNGAL ACTIVITY OF METABOLITES FROM STREPTOMYCES  
DIASTATOCHROMOGENES (NO.1628) AND ITS ACTIVE PRINCIPLE**

X. Shentu<sup>1</sup>, N. Liu<sup>1</sup>, Z. Ma<sup>1</sup>, X. Yu<sup>1</sup>

<sup>1</sup>College of Life Sciences, China Jiliang University, Hangzhou, China

**Background**

The fermentation broth by *Streptomyces diastatochromogenes* (No.1628), isolated from a soil sample collected in Mountain Tianmu, Hangzhou, China, had strong antifungal activity against *Alternaria solani*, *Botrytis cinerea*, *Fusarium oxysporum* and *Rhizoctonia solani*.

**Objectives**

The aim of this research is to isolation and identification of active compounds from *S. diastatochromogenes* 1628.

**Methods**

A bioactivity-guided approach was employed to isolate and determine the chemical identity of bioactive constituents with antifungal activity from *S. diastatochromogenes* 1628.

**Conclusions**

By the mycelium growth rate assay, it was showed that the n-butanol extract dosedependently inhibited growth of above tested phytopathogenic fungi with a potency at the concentration of 175 mg/L that was equal to that of commonly used antifungal agents at the concentrations tested. Furthermore, n-butanol extract of *S. diastatochromogenes* (No.1628) could effectively suppress and control cucumber rhizoctonia rot caused by *R. solani*. Through bioassay-guided fractionation, the n-butanol extract from *S. diastatochromogenes* (No.1628) afforded a new tetraene macrolide, (7E, 12Z,13E,15E,17E,19E) -21 -((4-amino-3,5-dihydroxy -6-methyltetrahydro -2H -pyran-2-yl)oxy) -12-ethylidene- 1,5,6,25 -tetrahydroxy -11 -methyl-9-oxo-10,27-dioxabi-cyclo[21.3.1]heptacos-7,13,15,17,19-pentaene-24-carboxylic acid (1), together with tetrin B (2), tetramycin A (3), toyocamycin(4) and anisomycin (5). The structures of compounds were established on the basis of spectroscopic analyses. This new compound strongly inhibited hyphal growth of *R. solani* and *B. cinerea* with IC<sub>50</sub> of 0.20 and 1.53 µg/mL, respectively. Our study demonstrated that *S. diastatochromogenes* (No.1628) is a promising source of natural bioactive and novel metabolites and has wide application prospect in biocontrol field.

**PANCREATIC LIPASE INHIBITORY ACTIVITY OF ENDOPHYTIC FUNGUS ASSOCIATED WITH AEGLE MARMELOS: A BIORESOURCE FOR NOVEL ANTI-OBESITY DRUG**

S. SAXENA<sup>1</sup>, M. GUPTA<sup>1</sup>, D. GOYAL<sup>1</sup>

<sup>1</sup>Department of Biotechnology, Thapar University, Patiala, India

**Background**

Obesity is a disease resulting from improper balance between energy intake and expenditure and is increasingly becoming a major cause of preventable mortality. Pancreatic lipase (PL) is considered as one of the safest target for diet-induced anti-obesity drug development.

**Objectives**

In the process of exploration of new PL inhibitors, we have screened culture filtrates of 200 endophytic fungi from different medicinal plants using qualitative and quantitative assays. The organism was identified and partial purification of the bioactive moiety was carried out using analytical techniques.

**Methods**

**Rhodamine olive oil plate assay** and PNPL (p-nitrophenyl laurate) as substrate was used for quantitative assessment of PL activity inhibition.

**Conclusions**

The qualitative assays indicated potential PL inhibition in 27 isolates. Further, only organic extract of these culture filtrates exhibited PL inhibition in range between 30-100%. #6 AMLWLS exhibited complete inhibition of PL with an IC<sub>50</sub> of 2.12 µg/ml which was comparable to the Orlistat exhibiting an IC<sub>50</sub> value of 2.73 µg/ml. Purification of the extract by column chromatography led to isolation of the pure compound which was identified as a tetra peptide molecule on the basis of C<sup>13</sup> NMR, HR/MS and biochemical analysis. Further molecular phylogenetic tools and morphological studies were used to identify the isolate #6 AMLWLS as *Fusarium incarnatum* species.

Hence endophytic fungal isolate #6 AMLWLS stands out as a potential candidate for anti-obesity therapy

**Background**

Bioprospecting using endophytic fungi is a promising source for the detection of novel compounds with biological activities of interest in health care, especially for diseases such as leishmaniasis (neglected tropical diseases) and cancer.

**Objectives**

The objective was to evaluate the cytotoxicity and the leishmanicide activity of endophytic fungi extracts isolated from *H. suaveolens* (L) Poit and *C. lanceolatum* Pohl against tumor cell lines MCF-7 and MDA-MB-231e *Leishmania amazonensis*.

**Methods**

We have evaluated 25 fungal culture extracts obtained by maceration of the mycelium in ethyl acetate (EtOAc). The fungi have isolated from *H. suaveolens* and *C. lanceolatum*. The extracts were tested against tumor cell lines MCF-7 and MDA-MB-231 and promastigotes forms of *L. amazonensis*. The test used was a colorimetric method with tetrazolium salt 3- [4,5-dimethylthiazol-2-yl] -2,5-diphenyltetrazolium bromide (MTT). The concentration of the extracts ranged from 100 to 12.50 µg/mL.

**Conclusions**

Extracts of 5 fungal isolates (*Taifanglania curticaenata*-F27; *Marasmius* sp.-21C, *Fusarium oxysporum*-33C; *Macrophomina phaseolina*-46C and *Trichoderma spirale*-66C) inhibited the proliferation of promastigotes at a low IC(50) of between 25.61 and 52.60 µg/ml. Six extracts (*M. phaseolina*- F1/46C; *T. curticaenata*-F27; *Cladosporium flabelliforme*- F29; *Neosartorya pseudofischeri*-F36, and *Corynespora cassiicola*-72C) were cytotoxic to both cell lines at a low IC(50) of between 23 and 48.72 µg/ml. Our results indicate that the medicinal plants living in wetlands Brazilian shelter an interesting bioactive fungal community that is able to produce leishmanicidal and antitumoral molecules. These molecules may be used to develop new leishmanicidal and anticancer drugs.

**Background**

Filamentous fungi are producers of a large number of valuable secondary metabolites due to their promising biological effects. Identification of these compounds and characterization of their biological activities are the important goals of research working at the interface of chemical and biological sciences.

**Objectives**

We aimed to verify the peptaibol production of a *Trichoderma* strain selected from the Szeged Microbiological Collection by a *Micrococcus luteus*-based agar plate screening method.

**Methods**

Mass spectrometric analysis of putative peptaibols produced by a *T. pleuroticola* strain have been carried out via on-line reversed-phase high performance liquid chromatography (HPLC) coupled to electrospray ionization ion trap mass spectrometry (ESI-IT-MS) after the solid phase clean-up of culture extracts. Initially, the separation and the mass spectrometric parameters were optimized using alamethicin standard peptaibol mixture and the unknown components produced by the selected isolate were investigated and determined.

**Conclusions**

Our mass spectrometric measurements confirmed the results of the biotest selection method used for the detection of peptaibols. Some of the produced peptaibols showed the characteristic mass spectral components of trichorzianins, including TA IIIb, TB IVb, TAP-14a and TA VII. However, besides the known molecules, seven new trichorzianin-related compounds were also detected; these contained some

amino acid changes in the core trichorzianin sequence. Comparing the amount of the different components, compounds with a molecular mass of 1909 amu were present in the highest amount. This research was supported by OTKA grant K-105972 from the Hungarian Scientific Research Fund and a bilateral grant from “Stiftung Aktion Österreich-Ungarn”.

### **Background**

An outstanding group of secondary metabolites are peptaibols, produced mainly by fungal species from the genus *Trichoderma*. These compounds show a wide spectrum of biological activities including antibacterial, antifungal and antiviral effects.

### **Objectives**

We aimed to develop a simple and easy-to-follow peptaibol characterization strategy including purification and structural elucidation steps, which can help to analyze the peptaibol-producing abilities of various isolates within the genus.

### **Methods**

Our characterization strategy includes the mass spectrometric analysis of the culture extracts of possible peptaibol-producing *Trichoderma* strains, the semi-preparative purification of the selected compounds, identification of amino acids in their sequences, and chiral analysis of the identified building blocks. These tasks require the use of microbiological methods for strain identification and for different cultivations and the application of separation techniques such as solid phase extraction, normal and reversed-phase HPLC and mass spectrometry.

### **Conclusions**

During the study, the different methodological steps were optimized and their application served the detailed characterization of some *Trichoderma* strains from the point-of-view of their peptaibol profiles. The examined isolates are belonging to the species *T. aggressivum*, *T. atroviride*, *T. longibrachiatum*, *T. orientale*, *T. pleuroticola*, *T. pleurotum* and *T. virens*. The peptaibol compositions showed high level of diversity and their amounts presented in a wide range. A number of already described compounds have been identified from species other than the original producer and novel peptaibols were also defined. This research was supported by OTKA grant K-105972 from the Hungarian Scientific Research Fund and a bilateral grant from "Stiftung Aktion Österreich-Ungarn".

### **Background**

Ophiobolins are a remarkable family of secondary metabolites with various biological activities such as calmodulin antagonism, cytotoxic, antimicrobial and nematocid effects.

### **Objectives**

Our aim was to develop a rapid and efficient method for purification of different bioactive sesterterpene-type fungal secondary metabolites belonging to the ophiobolin family.

### **Methods**

Based on our preliminary results, a *Bipolaris oryzae* strain was selected and cultivated in PDB. The ferment broth was extracted with ethyl-acetate and concentrated. The purification of the crude extract was carried out using subsequent semi-preparative liquid chromatographic techniques. Initially, normal phase column chromatography was carried out using the mixture of ethyl-acetate and n-hexane, and the fractions containing large amount of potential ophiobolin compounds were further purified on a semi-preparative reverse phase HPLC system with the mobile phases of acetonitrile and water. After each purification step, the collected fractions were analyzed on an analytical HPLC system to determine their purity. The purified compounds were identified using mass spectrometric and NMR experiments.

### **Conclusions**

The selected *B. oryzae* strain produced several ophiobolin analogues. The purified compounds synthesised in the highest amount proved to be ophiobolin A; its identity was confirmed with HPLC-MS and NMR experiments. Besides ophiobolin A, four other ophiobolin analogues were also purified including 3-anhydro-ophiobolin A,

ophiobolin I, 6-epi-ophiobolin A and 3-anhydro-6-epi-ophiobolin A with the purities over the 95%. This research was supported by grant TÁMOP-4.1.1.C-12/1/KONV-2012-0012. Csaba Vágvolgyi thanks the visiting professor program, Deanship of Scientific Research, King Saud University, Riyadh.

**RECOMBINANT PRODUCTION OF BIOSURFACTANTS WITH ENGINEERED  
PSEUDOMONAS PUTIDA**

T. Tiso<sup>1</sup>, L. Blank<sup>1</sup>

<sup>1</sup>iAMB - Institute of Applied Microbiology, RWTH Aachen University, Aachen,  
Germany

**Background**

Rhamnolipids are potent biosurfactants with high potential for industrial applications. They are currently produced with the opportunistic pathogen *Pseudomonas aeruginosa* during growth on hydrophobic substrates such as plant oils. The heterologous production of rhamnolipids enables the use of a non-pathogenic host and cheaper substrates such as glucose. Glucose also has the advantage of simpler purification, e.g., via coupled foam fractionation and adsorption [1].

**Objectives**

To engineer a non-pathogenic rhamnolipid producer converting glucose or other renewable resources efficiently into the target product.

## Methods

Introduction of the biosynthesis pathway for rhamnolipids from *P. aeruginosa* in the non-pathogenic *P. putida*. Metabolic engineering of secondary metabolite producers implicitly relies on high flux through central carbon metabolism. Our strategy relies on the ability of *P. putida* to reroute metabolic resources into a peripheral pathway when a high demand exists, e.g., initiated by high transcriptional activity.

## Conclusions

We previously presented a recombinant *P. putida* able to produce 0.2 g/L rhamnolipids [2]. For optimization, several techniques were used. A synthetic promoter library was developed using an approach based on degenerated primers [3]. This technique yields an array of transcriptional activity, potentially allowing the identification of optimal enzyme activity for high flux towards rhamnolipid synthesis. The second step was eliminating a pathway competing for a common precursor. The best producing strain was able to reach a titer of 3 g/L with a yield of 40% and a very high specific rhamnolipid synthesis rate, which is possible because the flux through the precursor providing pathways is significantly increased in the engineered strain.

## **FUNCTIONAL CHARACTERIZATION OF A GENE INVOLVED IN THE BIOSYNTHESIS OF MYCOPHENOLIC ACID IN THE FUNGUS *PENICILLIUM ROQUEFORTI***

I. Vaca<sup>1</sup>, A. Del-Cid<sup>2</sup>, C. Gil-Durán<sup>2</sup>, R. Chávez<sup>2</sup>

<sup>1</sup>Departament of Chemistry, Universidad de Chile, Santiago, Chile

<sup>2</sup>Departament of Biology, Universidad de Santiago de Chile, Santiago, Chile

### **Background**

*Penicillium roqueforti* is a filamentous fungus used in the ripening of blue-veined cheeses. Previous studies have shown that this organism produces several secondary metabolites, including mycophenolic acid, a meroterpenoid with immunosuppressive activity of great pharmaceutical interest. However, the genes involved in the synthesis of this metabolite in *P. roqueforti* have not been described or characterized so far. In other organisms such as *P. brevicompactum*, it has been described that the mycophenolic acid biosynthetic cluster consists of seven genes, among them *mpaDE*, which encodes for a natural fusion enzyme consisting of a cytochrome P450 and a hydrolase.

### **Objectives**

To evaluate the role of the *mpaDE* gene in the biosynthesis of mycophenolic acid in *P. roqueforti*.

### **Methods**

The genome of *P. roqueforti* was analyzed using bioinformatic tools and an ORF that corresponds to the hypothetical orthologue of *mpaDE* was identified. The expression of this gene was down regulated using RNAi-silencing technology. For this purpose, *P. roqueforti* was transformed with an appropriate genetic construct, and several transformants strains showing dramatic reductions in the levels of *mpaDE* transcript were selected. Finally, extracts from these transformants were analyzed by HPLC.

### **Conclusions**

*P. roqueforti* wild-type showed high levels of mycophenolic acid. On the contrary, the transformants showed barely detectable levels of this metabolite. These results indicate that *mpaDE* is involved in the biosynthesis of mycophenolic acid in *P. roqueforti*.

**A UNIQUE GLUCOSE SENSOR GCR1 OF THE METHYLOTROPHIC YEAST HANSENULA POLYMORPHA CAN TRANSPORT MONOSACCHARIDES**

I. Denega<sup>1</sup>, N.O. Sybirna<sup>1</sup>, O.V. Stasyk<sup>2</sup>, O.G. Stasyk<sup>1</sup>

<sup>1</sup>Department of Biochemistry, Ivan Franko National University of Lviv, Lviv, Ukraine

<sup>2</sup>Department of Cell Signalling, Institute of Cell Biology NAS of Ukraine, Lviv, Ukraine

**Background**

Several proteins involved in glucose sensing, signalling and transport have been described for methylotrophic yeast *Hansenula polymorpha*. Among them Gcr1, a peculiar C-tale-less glucose sensor, required for glucose repression and regulation of hexose transport.

**Objectives**

The aim of this work was to further elucidate the *H. polymorpha* Gcr1 protein function in glucose transport.

**Methods**

Wild type NCYC495 (WT) and mutant strains of *H. polymorpha*, classical methods of molecular genetics and microbiology were used.

**Conclusions**

The closest homologue for glucose sensor Gcr1 of *H. polymorpha* is the functional high-affinity monosaccharide transporter involved in H<sup>+</sup>-dependent glucose symport – MstA from *Aspergillus niger*. Regulated *HpGcr1* production in hexose transporter-less *Saccharomyces cerevisiae* mutant did not restore growth of this strain on different glucose concentrations. Similarly to Gcr1, functional high-affinity glucose transporters of *Trichoderma harzianum* Gtt1 and *Aspergillus nidulans* HxtA did not complement growth deficiency of *S. cerevisiae* *hxt null* on different carbohydrate substrates. Grown on methanol-containing medium WT-derivative strains with constitutive expression of *GCR1* and *HXT1* encoding low-affinity hexose transporter were more sensitive to exogenous glucose antimetabolite 2-deoxy-D-glucose (2-DOG) (concentration 0.3 mM) compared to the WT strain. The toxic effect of 2-DOG was more acute on medium with lower pH. Therefore, Gcr1 can possibly transport glucose toxic analogue into cells, thus increasing its harmful effects.

*H. polymorpha* protein Gcr1 that most probably results from a horizontal transfer from *Aspergillus* fungi, is essential for glucose catabolite repression of genes involved in metabolism of alternative carbon substrates and "very-high affinity" glucose transport.

## **DESIGNING FUNCTIONAL HETERODIMERS TO DECIPHER SIGNAL TRANSDUCTION IN BVGS**

E. Dupré<sup>1</sup>, R. Antoine<sup>1</sup>, C. Locht<sup>1</sup>, F. Jacob-Dubuisson<sup>1</sup>

<sup>1</sup>Center for Infection and Immunity of Lille, Institut Pasteur de Lille, Lille, France

### **Background**

The virulence of *Bordetella pertussis*, the whooping cough agent, is regulated by the two-component system BvgAS. BvgA is a classical response regulator while BvgS is an unorthodox sensor-kinase harboring receiver and Histidine phosphotransfer domains. BvgS contains three putative perception domains, two periplasmic Venus Flytrap domains linked by a transmembrane segment to a cytoplasmic PAS domain. The kinase of BvgS is active by default and is turned off by negative modulators such as nicotinate or sulfate ions.

### **Objectives**

BvgS functions as a homodimer, and its phosphorylation cascade works in trans. We took advantage of this property to construct a merodiploid strain in which only heterodimers, but not homodimers, are functional to decipher the signal transduction mechanism involved in BvgS.

### **Methods**

We introduced point mutations in the various sensor domains to test their effect in heterodimers. The same substitutions in the context of a wild type phosphorylation cascade affect either the basal kinase activity of BvgS or its ability to respond to modulation, as seen using a *lacZ* reporter gene under the control of a virulence gene promoter.

### **Conclusions**

When substitutions affecting the response to modulation are introduced in the periplasmic VFT domains of BvgS, the WT monomer is able to partly compensate for the defect of the other monomer, yielding intermediate phenotypes. In contrast, the substitutions introduced in the PAS domain appear to be dominant over a wild type PAS domain. This suggests that signal transduction is achieved through different mechanisms in the periplasmic and cytoplasmic moieties of BvgS.

**THE STRUCTURE AND FUNCTION OF ISOLATED N-TERMINAL AMPHIPATHIC  
HELIXES OF MEMBRANE STRESS CONTROLLERS PSPA AND VIPP1**

C. McDonald<sup>1</sup>, M. Buck<sup>1</sup>, B.A. Wallace<sup>2</sup>, O. Ces<sup>3</sup>, G. Jovanovic<sup>1</sup>

<sup>1</sup>*Department of Life Sciences, Imperial College London, London, United Kingdom*

<sup>2</sup>*Institute of Structural and Molecular biology Birkbeck College, University of London, London, United Kingdom*

<sup>3</sup>*Department of Chemistry, Imperial College London, London, United Kingdom*

**Background**

All cell types maintain the integrity of their membrane. One widely distributed plasma membrane stress response system in bacteria is the phage shock protein (Psp) system. Its central component PspA has a counterpart Vipp1. Both proteins are directly responsible for membrane maintenance under stress conditions while PspA also negatively regulates its own expression via interaction with the AAA+ ATPase PspF.

**Objectives**

The PspA and Vipp1 N-terminal amphipathic helix A (ahA) is implicated in their membrane binding, and ahB in PspA is required for negative regulation. A direct interaction between ahA and the lipid bilayer for effector function and ahB and PspF for regulatory function has yet to be determined.

**Methods**

Purified short peptides derived from the amphipathic helices were used to directly probe membrane binding and regulatory function. Defined membrane vesicle *in vitro* assays and CD spectroscopy characterised the functionalities of the ahs and the downstream effects on membrane stability and transcription regulation.

**Conclusions**

We observed direct membrane-binding of ahA derived peptides and in the case of Vipp1 an accompanying change in secondary structure from random coil to alpha

helical upon membrane association. Binding specificity by varying the membrane anionic lipid content and stored curvature elastic stress linked the functionalities of the peptides with those of full length proteins. ahB of PspA inhibited the ATPase of PspF proving its direct regulatory role. These findings establish synthetic peptides can probe PspA structure-function and target regulation of the Psp response, which could be of interest for controlling pathogens where Psp response is important and conserved.

## **NEW INSIGHTS IN THE ACTIVATION OF THE PSEUDOMONAS AERUGINOSA VIRULENCE REGULATOR SIGMA VREI AND THE PUMA3 CELL-SURFACE SIGNALING SYSTEM**

J. Otero-Asman<sup>1</sup>, J.M. Quesada<sup>1</sup>, C. Civantos<sup>1</sup>, K.C. Bastiaansen<sup>2</sup>, M.A. Llamas<sup>1</sup>

<sup>1</sup>Environmental protection, Estación Experimental del Zaidín-

Consejo Superior de Investigaciones Científicas, Granada, Spain

<sup>2</sup>Molecular Cell Biology, VU University Amsterdam, Amsterdam, Netherlands

### **Background**

Cell-surface signaling (CSS) is a regulatory mechanism used by gram-negative bacteria to modify gene expression in response to environmental signals. CSS regulation is extensively present in the human opportunistic pathogen *Pseudomonas aeruginosa*. Most CSS systems of this bacterium regulate iron uptake. However, the PUMA3 CSS system regulates virulence. *P. aeruginosa* PUMA3 is constituted by the VreA receptor, the VreR anti-sigma factor and the  $\sigma^{\text{Vrel}}$  extracytoplasmic function (ECF) sigma factor. VreR binds to and keeps inactive  $\sigma^{\text{Vrel}}$  in absence of the PUMA3 inducing signal. The role of VreA is to sense the presence of the signal and to transduce it to the VreR anti-sigma factor allowing the release and activation of  $\sigma^{\text{Vrel}}$  and the expression of the PUMA3 regulated genes.

### **Objectives**

The PUMA3 inducing signal is still unknown. However it has been recently shown that expression of the *vreAIR* operon is induced in low phosphate (Pi). In this condition, some degree of  $\sigma^{\text{Vrel}}$  activity is also observed despite the fact that the VreR anti-sigma factor is also produced. In this work, we aimed at analyse the role of VreA and VreR in both the expression and the activation of  $\sigma^{\text{Vrel}}$  in low Pi.

### **Methods**

*P. aeruginosa* *vreR* and *vreA* deletion mutants has been constructed by allelic exchange. Gene expression was monitored using *lacZ* transcriptional fusions.  $\sigma^{\text{Vrel}}$  stability has been assayed by Western-blot.

### **Conclusions**

Full activation and stability of  $\sigma^{\text{Vrel}}$  in low Pi requires the removal of VreR and the presence of an additional inducing signal that targets this process.

## **IMPACT OF POTENTIAL IN VIVO DIVK DIMERIZATION ON CAULOBACTER CRESCENTUS CELL CYCLE**

L. Schille<sup>1</sup>, F. Tilquin<sup>1</sup>, J.Y. Matroule<sup>1</sup>

<sup>1</sup>Microorganisms Biology Research Unit, UNamur, Namur, Belgium

### **Background**

Response regulators are crucial actors of two-component systems and have often been shown to dimerize. We focus on DivK, an essential single domain response regulator of the aquatic  $\alpha$ -proteobacterium *C. crescentus*. DivK is part of a phosphorelay controlling developmental events and belongs to the same protein subfamily as CheY and Spo0F, two response regulators known to dimerize. A previous study has highlighted DivK dimerization *in vitro* (Guillet *et al.*, The Journal of Biological Chemistry, 2002) but the relevance of this dimerization *in vivo* is still a mystery.

### **Objectives**

The goal of our research is (i) to assess whether DivK is able to dimerize *in vivo* and (ii) to determine whether this dimerization mediates DivK subcellular localization and/or the interaction with potential partners. We are also interested in investigating the importance of DivK phosphorylation in its dimerization.

### **Methods**

Under native conditions, DivK appears as a doublet which is not visible under reducing conditions. Interestingly, the relative intensity of the DivK bands varies when the PleC phosphatase or the DivJ kinase, both acting on DivK, are knocked-out. In addition, the doublet is upshifted in the DivK<sub>D90G</sub> mutant, whose subcellular localization is affected. The nature of this doublet is currently under investigation. We are also trying to identify DivK partners by MS-MS analysis of DivK co-immunoprecipitates obtained from various genetic backgrounds.

### **Conclusions**

Preliminary results suggest that DivK is indeed able to dimerize *in vivo* and to bind different partners. This dimerization could be triggered by phosphorylation.

**Small regulatory RNAs**

**USE OF ANTISENSE RNA TO MODULATE HSP GENE EXPRESSION IN  
OENOCOCCUS OENI**

M. Darsonval<sup>1</sup>, C. Grandvalet<sup>1</sup>, T. Msadek<sup>2</sup>, H. Alexandre<sup>1</sup>

<sup>1</sup>Equipe VALMiS, Institut de la Vigne et du Vin, Dijon, France

<sup>2</sup>Unité de biologie des bactéries pathogènes à Gram positif, Institut Pasteur, Paris, France

**Background**

*Oenococcus oeni* is a wine-associated lactic acid bacterium responsible for wine malolactic fermentation. Wine exhibits harsh and challenging *conditions*: low pH, low temperature, nutrient-poor and presence of ethanol leading to *O. oeni* stress response. Understanding of the mechanisms involved in stress tolerance is essential to improve *O. oeni* development in wine.

Stress adaptation of *O. oeni* has been studied and many *hsp* genes, induced in oenological conditions, have been identified. The *hsp18* gene, encoded the small Hsp Lo18, have been particularly characterized. In addition to its chaperon activity, Lo18 could have a lipochaperon-function and maintains membrane integrity in stress conditions.

**Objectives**

Up to now, characterization of *O. oeni* genes was restricted due to lack of genetic tools for gene replacement. Accordingly, we focused our work on gene inactivation by using antisense RNA approach to modulate *hsp* gene expression in *O. oeni*. With the goal of understanding the function of *O. oeni hsp* genes *in vivo*, we have developed an efficient expression vector to produce antisense RNA targeting *hsp18* mRNA and reduce sense RNA transcript.

**Methods**

After transformation into *O. oeni*, transformants were exposed to multiple stresses inducing *hsp18* gene expression: heat shock, acid shock and presence of ethanol.

**Conclusions**

We highlighted that *in vivo* antisense inhibition of *hsp18* expression strongly affects the survival of *O. oeni* in stress conditions. This study presents a new efficient genetic tool for *O. oeni* and demonstrates for the first time the use of antisense technology for modulating gene expression in *O. oeni*.

## **DIFFERENTIAL EXPRESSION OF SMALL RNAs IN RESPONSE TO CHEMICAL STRESS**

*M.H. Rau<sup>1</sup>, K. Bojanovic<sup>1</sup>, A.T. Nielsen<sup>1</sup>, K.S. Long<sup>1</sup>*

*<sup>1</sup>Novo Nordisk Foundation Center for Biosustainability,  
Technical University of Denmark, Hoersholm, Denmark*

### **Background**

Bacterial sRNAs are often expressed in response to changing environmental conditions and function to modulate gene expression. There are numerous documented connections between sRNAs and stress, where sRNAs regulate important processes in response to metabolite, envelope, oxidative, iron deficiency, anaerobic and pH stress.

### **Objectives**

Although chemical stress is routinely encountered in microbial processing applications due to the toxicity of substrate, intermediate or product compounds, the cellular response and the involvement of sRNAs in this process is poorly understood. We have used an RNA sequencing approach to map the *E. coli* sRNome during chemical stress and high cell density fermentations with the aim of gaining insights into the chemical stress response and identifying sRNAs with roles in stress tolerance that have potential applications in the design and optimization of future production strains.

### **Methods**

RNA sequencing libraries were prepared from RNA isolated from *E. coli* MG1655 cells subjected to chemical stress with twelve compounds including organic acids, amino acids, and organic solvent-like compounds. The *E. coli* MG1655 strain was also grown under high cell density fermentation conditions, where cells were harvested in exponential batch, glucose-limited exponential fed-batch, transition and stationary growth phases.

### **Conclusions**

Over 250 novel intergenic sRNAs have been identified with this approach, adding to the roughly 200 previously reported sRNAs in *E. coli*. A significant fraction of the sRNAs exhibit specific expression patterns during high cell density fermentation and

a group of them are differentially expressed in the presence of multiple chemicals, suggesting they may play regulatory roles during these stress conditions.

**HFQ BINDING PROFILES OF SRNAS AND THEIR TARGET MRNAS**

S. Melamed<sup>1</sup>, L. Argaman<sup>1</sup>, R. Faigenbaum-Romm<sup>1</sup>, A. Peer<sup>1</sup>, Y. Altuvia<sup>1</sup>,  
H. Margalit<sup>1</sup>

<sup>1</sup>*Microbiology and Molecular Genetics, Hadassah-Hebrew University Medical Center, Jerusalem, Israel*

**Background**

Bacterial sRNAs are 50-400 nucleotide-long RNA molecules, most of which exert their regulation by base-pairing with their target mRNAs. In many bacteria, including *Escherichia coli*, the interaction between an sRNA and its targets is mediated by the Hfq protein, resembling the situation in eukaryotic cells where the interaction of a microRNA and its targets involves Argonaute. While it is widely accepted that miRNAs guide Argonaute proteins to their specific targets through sequence complementarity, the dynamics of sRNA-Hfq-target interaction, to the best of our knowledge, has not been yet fully determined.

**Objectives**

As a first step towards this question, we study the relationship between the levels of Hfq-bound sRNA and its target mRNAs. More specifically, we aim to measure the change in Hfq-bound target mRNA levels following a change in the expression level of their sRNA regulator.

**Methods**

To this end we applied RNA-seq to measure the levels of total RNA and RNA co-IPed with Hfq from three *E. coli* strains (MG1655 Hfq-FLAG, MG1655 hfq::kan and MG1655 Hfq-FLAG rnc14::Tn10) with and without overexpression of the sRNA MicA.

**Conclusions**

Our results indicate that most MicA target mRNAs, as well as MicA itself, were enriched in Hfq when MicA was overexpressed. In contrast, most target mRNAs of other sRNAs were depleted. In conclusion, our initial results indicate that there is a relationship between sRNA and target mRNA levels on Hfq, offering a strategy to identify putative novel targets.

**THE TRANSCRIPTOME LANDSCAPE OF LACTOCOCCUS LACTIS MG1363:  
SMALL REGULATORY RNAs UNCOVERED**

S. van der Meulen<sup>1</sup>, A. de Jong<sup>1</sup>, J. Kok<sup>1</sup>

<sup>1</sup>Molecular Genetics, University of Groningen, Groningen, Netherlands

**Background**

RNA sequencing has recently revolutionized transcriptome analyses. As a result, novel non-coding RNAs have been discovered in several organisms and subsequent studies have revealed an increasing number of new regulatory mechanisms at the level of RNA. The lactic acid bacterium *Lactococcus lactis* is of high importance for biotechnological applications, specifically in the dairy industry. The stress response systems are very well studied for this bacterium. In addition, global regulators of carbon and nitrogen metabolism have also been studied in detail. However, the presence and roles of non-coding RNAs with regulatory functions has not been assessed until now.

**Objectives**

We aimed to identify novel RNA elements, such as small regulatory RNAs, antisense RNAs and sORFs. In addition, expression of these novel RNAs under various stress conditions was assessed, and for one novel sRNA, the function was studied in depth.

**Methods**

By using differential RNA sequencing (dRNA-seq) data, a transcriptome landscape of *L. lactis* was constructed that was used for manual and automated mining using TSSer. Northern hybridization was used to confirm 12 putative regulatory RNAs.

**Conclusions**

This study used both manual and automated approaches to identify hundreds of novel RNA species. Experimental validation was performed for a selection of these potential RNA regulators. The role of one non-coding RNA located in the 3'UTR of *argR*, the regulator of e.g. the *arc*-operon in *L. lactis*, is currently being examined. This small RNA, called ArgX, appears to stabilize the *arc*-operon. Results of this sRNA ArgX and its role in regulating *arc*, will be presented.

### Background

Gram-positive bacteria reduces the effectiveness of cationic antimicrobial peptides (CAMPs), such as colistin, and preserves cell integrity by the addition of D-alanine to lipoteichoic acids (LTAs). Thus far, no small RNA (sRNA) has been described to be involved in the regulation of the genes involved in the D-alanylation of LTAs in the human neonatal pathogen Group B *Streptococcus* (GBS).

### Objectives

Here, we present the first study describing the functional characterization of a GBS sRNA. We highlight its pleiotropic role in maintaining cell integrity and colistin resistance.

### Methods

The GBS sRNA was identified by RNAseq and its expression was confirmed by northern blot analyses. The biological role of the sRNA was investigated by analyzing a deletion mutant ( $\Delta srna$ ). The interaction region between the sRNA and its mRNA target was predicted *in silico* and confirmed by *in vivo* mutagenesis.

## Conclusions

The northern blot analyses showed that the sRNA is mainly expressed at the onset of the stationary phase until late stationary phase. Microscopic observations showed that the  $\Delta srna$  strain forms significantly shorter chains, and is more sensitive to colistin (MIC = 16  $\mu\text{g/mL}$ ) when compared to the wild-type (MIC > 256  $\mu\text{g/mL}$ ). Interestingly, the *in silico* predicted mRNA target is downregulated in the mutant strain. Mutations in the sRNA sequence likely involved in RNA-RNA pairing are sufficient to provoke similar chains alterations than the  $\Delta srna$  strain. All together, these results suggest that the sRNA is required for colistin resistance and cell integrity due to a direct regulation of the D-alanylation pathway.

**DEVELOPMENT OF OAPV3 VIRAL-LIKE PARTICLES FOR INVESTIGATION OF SHEEP HUMORAL IMMUNE RESPONSE TO PAPILLOMAVIRUS INFECTION**

G.M. Dore<sup>1</sup>, C. Cacciotto<sup>1</sup>, G. Tore<sup>1</sup>, M. Pittau<sup>1</sup>, P. Galmbacher<sup>2</sup>, M. Müller<sup>2</sup>,  
A. Alberti<sup>1</sup>

<sup>1</sup>*Department of Veterinary Medicine, University of Sassari, Sassari, Italy*

<sup>2</sup>*Research Group Tumovirus-specific Vaccination Strategies,  
German Cancer Research Center, Heidelberg, Germany*

**Background**

Papillomaviruses are a diverse group of small, non-enveloped, double stranded DNA viruses that cause proliferations of the stratified squamous epithelium of the skin and mucosa in a wide variety of vertebrate hosts. Papillomaviruses play an important role in human cancer development, and have been isolated from a number of animal malignancies. Recently we identified a novel ovine papillomavirus, OaPV3, associated with squamous cell carcinoma. Like other papillomaviruses, OaPV3 is not able to productively infect cells in culture. The lack of *in vitro* factories for viral production hampers the investigation of pathogenetic mechanisms and interaction with host immune response.

**Objectives**

Main goal of this study is the production of non-infectious OaPV3 viral-like particles (VLPs) for evaluating humoral immune response in naturally infected sheep.

**Methods**

Non-infectious VLPs were obtained by expressing the L1 major capsid protein in insect cells using recombinant baculoviruses. Two sheep were immunized with OaPV3 VLPs. Sera were collected after each of the 3 immunisations. VLPs were used in western blotting and ELISA to test reactivity of 90 sera collected from sheep sampled in flocks naturally infected by OaPV3.

**Conclusions**

Data indicate a specific immune response of immunised sheep. In naturally infected flocks, only sheep with clinical lesions showed detectable antibodies. OaPV3, like human cutaneous papillomavirus seems to escape humoral response by playing “hide and seek” with host immune system.

**FEMS-3071**

**GENOME CHARACTERIZATION AND CELLULAR TROPISM OF OAPV4, A NOVEL OVINE PAPILLOMAVIRUS ISOLATED FROM SHEEP FIBROPAPILLOMAS**

G. Tore<sup>1</sup>, G. Burrai<sup>1</sup>, A.G. Anfossi<sup>1</sup>, C. Cacciotto<sup>1</sup>, G.M. Dore<sup>1</sup>, S. Pau<sup>1</sup>, G. Masala<sup>1</sup>, M. Pittau<sup>1</sup>, E. Antuofermo<sup>1</sup>, S. Pirino<sup>1</sup>, A.G. Alberti<sup>1</sup>

<sup>1</sup>Department of Veterinary Medicine, University of Sassari, Sassari, Italy

**Background**

Papillomaviruses play an important role in human cancer development, and have been isolated from benign and malignant proliferative skin lesions. However, the association of papillomaviruses with cutaneous lesions has been poorly investigated in sheep. To date, three ovine papillomaviruses types have been classified. OaPV1, OaPV2 belong to *Deltapapillomaviruses* genus and were found in cutaneous fibropapillomas of Australian Merinos. OaPV3 belongs to a new genus, *Dyokappa*, and has been recovered from cutaneous squamous cell carcinomas of Sarda breed sheep.

**Objectives**

In this study we investigated unknown ovine papillomaviruses in cutaneous fibropapillomas of Sarda breed sheep.

**Methods**

Rolling circle amplification was performed on total DNA extracted from skin lesions biopsies, and resulted in the presence of a novel ovine Papillomavirus (OaPV4). The entire OaPV4 genome was cloned and sequenced. IHC with L1 antibodies and ISH with E6 dig-probe were carried out in order to establish viral cellular tropism.

**Conclusions**

A novel papillomavirus, OaPV4, was identified. Viral L1 shares 82.5% nucleotide homology with the closest relative (OaPV1). Maximum likelihood phylogenetic tree placed OaPV4 in a monophyletic clade including all *Deltapapillomaviruses* so far described.

OaPV4 infects both epithelial cells and fibroblasts and has a role only in benign lesion development. This is the first report of a *Deltapapillomavirus* 3 species in European Sarda breed, and this supports the existence of an OaPV1/OaPV4 common ancestor infecting sheep before radiation and evolution of modern sheep breeds.

## **EQUUS ASINUS PAPILLOMAVIRUS (EAPV1) PROVIDES NEW INSIGHTS INTO EQUINE PAPILLOMAVIRUS DIVERSITY**

*R. Lecis<sup>1</sup>, G. Tore<sup>1</sup>, A. Scagliarini<sup>1</sup>, E. Antuofermo<sup>1</sup>, C. Dedola<sup>1</sup>, C. Cacciotto<sup>1</sup>, G.M. Dore<sup>1</sup>, A.G. Anfossi<sup>1</sup>, M. Muzzeddu<sup>1</sup>, M. Pittau<sup>1</sup>, A. Alberti<sup>1</sup>*

*<sup>1</sup>Department of Veterinary Medicine, University of Sassari, Sassari, Italy*

### **Background**

The Papillomaviridae family consists of a large and diverse group of viruses characterised by a double strand, covalently linked circular genome typically ranging from 7 to 8 kb in size, and causing proliferative lesions in animals and human.

### **Objectives**

Aim of this study was to investigate papillomavirus diversity in Equidae and to establish the presence of PV in species related to horse. We detected a novel papillomavirus (EaPV1) from healthy skin and from sun associated cutaneous lesions of an Asinara (Sardinia, Italy) white donkey reared in captivity in a wildlife recovery centre. EaPV1 genome is 7467 bp long, and shows some characteristic elements of horse papillomaviruses, including a small untranslated region between the early and late regions. A typical E6 ORF is missing. EaPV1 DNA was detected in low copies in normal skin of white and grey donkeys of the Asinara Island, and does not transform rodent fibroblasts in standard transformation assays. Pairwise nucleotide alignments and phylogenetic analyses based on concatenated E1-E2-L1 amino acid sequences revealed the highest similarity with the Equine papillomavirus type 1.

### **Methods**

The entire genome of EaPV1 was cloned, sequenced, and characterised. Methods included: DNA extraction, traditional and real-time PCR, RCA, cloning, sequencing and phylogenetic analyses.

### **Conclusions**

The discovery of EaPV1, the prototype of a novel genus and the first papillomavirus isolated in donkeys, confirms a broad diversity in Equidae papillomaviruses. Taken together, data suggest that EaPV1 is a non-malignant papillomavirus adapted to healthy skin of donkeys.

**BACTERIOSTATIC SYNERGISTIC EFFECT OF RECOMBINANT HUMAN LACTOFERRIN, SILVER AND ZINC NANOPARTICLES ON PATHOGENIC ENTERIC BACTERIA ISOLATED FROM DIARRHEAL CALVES**

D. Barysavets<sup>1</sup>, P. Krasachka<sup>1</sup>, I. Krasachka<sup>1</sup>, G. Taliaronak<sup>1</sup>, P. Chaikouski<sup>1</sup>, I. Semak<sup>2</sup>

<sup>1</sup>*Virological,*

*RUE "Institute of Experimental Veterinary Medicine named of S.N. Vyshesleski",  
Minsk, Belarus*

<sup>2</sup>*Biochemistry, Belarusian State University, Minsk, Belarus*

**Background**

The spread of multidrug-resistant Enterobacteriaceae is complicating the treatment of diarrhea in neonatal calves. Growing resistance of microorganisms to antibiotics requires to find novel effective antibacterial drugs.

**Objectives**

To evaluate the bacteriostatic effect of human lactoferrin (hLf), silver nanoparticles (AgNPs), zinc nanoparticles (ZnNPs) and their combinations on pathogenic enteric bacteria isolated from diarrheal calves.

**Methods**

Recombinant hLf was isolated from milk of transgenic goats generated by microinjecting sequence encoding hLf cDNA to the pronuclear. AgNPs and ZnNPs were prepared by chemical methods. The radii of particles were between 20 and 25 nm. *E.coli*, *Pr. mirabilis* and *Kl. pneumoniae* used in these experiments were isolated from diarrheal calves. Isolated bacteria were resistant to ciprofloxacin and erythromycin. To evaluate the bacteriostatic effect of hLf, nanoparticles and their combinations the broth microdilution minimal inhibitory concentration (MIC) testing was applied.

**Conclusions**

The results suggested that the MIC value of AgNPs against *E.coli*, *Pr. mirabilis* and *Kl. pneumoniae* was about 2-4 µg/ml; ZnNPs activity was lower (about 8-16 µg/ml). The synergistic antimicrobial effect between hLf and NPs was also evident. The MICs of hLf decreased when used together with NPs. So the MIC of hLf against all of the tested bacterial strains was reduced from 4-8 mg/ml when used alone to 0,5-2 mg/ml when used in conjunction with 1 µg/ml of AgNPs. The synergistic activity of hLf and ZnNPs combination was less pronounced. The best synergistic combination was AgNPs and hLf that allows to recommend it for the treatment of diarrhea in neonatal calves.

**EFFECTS OF COLD STRESS ON BACTERIAL ISOLATION AND IMMUNE CELLS IN CAMPYLOBACTER JEJUNI INFECTED SPF CHICKENS.**

A. BORSOI<sup>1</sup>, W.M. QUINTEIRO-FILHO<sup>1</sup>, A.S. CALEFI<sup>1</sup>, J. PALERMO-NETO<sup>1</sup>

<sup>1</sup>Department of Pathology Faculty of Veterinary Medicine and Zootechny, University of São Paulo, SAO PAULO, Brazil

**Background**

Stress activate the hypothalamic-pituitary-adrenal axis and the sympathetic nervous system resulting in a series of neural and endocrine adaptations. In industrial production the cold stress are one of the most important problem in the first week of poultry production. Many microorganisms are present in the livestock and poultry products are considered main source of *Campylobacter jejuni* to humans.

**Objectives**

Our aims were challenge chickens with cold stress and *Campylobacter jejuni* (ATCC33291) infection to assess the role of stress in the interaction host-pathogen

**Methods**

Thirty-two Leghorn SPF birds were housed in isolators divided into three groups: C (negative control not shown), CI (*Campylobacter jejuni* infected -  $10^4$  ufc) kept for 21 days in thermal comfort and the group CI+CS (*Campylobacter jejuni* infected -  $10^4$  ufc + cold stress) was subjected to cold stress for 6 h per day during 7 days at a 19°C. At 7 and 21 days old, bacterial isolation from liver and cecum, blood flow cytometry to CD45, CD3, CD4 and CD8 antibodies, plasma corticosterone (CS) (Fig.1) and blood glucose (BG) levels were performed in the birds.

**Conclusions**

We observed high BG and CS ( $p<0,005$ ) during entire experiment in CI+CS group. Also, the cold stress increased bacterial isolation at 21days in the liver and cecum (Fig. 2). At 21days of age, we observed a increase of CD3+ ( $p<0,05$ ) CD4+ and CD8+ peripheral cells in CI+CS group (Fig.3). We may conclude that high CS and BG in birds subjected to cold stress affect negatively the bacterial clearance and immune cells distribution.

**Veterinary microbiology**

**MYCOPLASMA AGALACTIAE ESCAPES SHEEP NEUTROPHIL  
EXTRACELLULAR TRAPS (NETS)**

C. Cacciotto<sup>1</sup>, A. Anfossi<sup>1</sup>, G. Tore<sup>1</sup>, G.M. Dore<sup>1</sup>, M. Pittau<sup>1</sup>, A. Alberti<sup>1</sup>

<sup>1</sup>Department of Veterinary Medicine, University of Sassari, Sassari, Italy

**Background**

Mycoplasmas are the smallest self-replicating bacteria that evolved a parasitic lifestyle through regressive evolution. The ability of mycoplasmas to modulate immune responses allows the establishment of persistent infection resulting in chronic inflammatory diseases. Mycoplasmas evolved different strategies to escape host immune system. Despite mechanisms of humoral response evasion are known, resistance to innate response is still insufficiently investigated.

To date, studies of interaction between mycoplasmas and granulocytic neutrophils are still lacking. NETs are a mixture of antimicrobial peptides and proteins "caught" in a backbone of DNA filaments that trap bacteria, which are cleared by macrophage through phagocytosis. It has been demonstrated that *Staphylococcus aureus* (*S. aureus*) breaks down NETs through its SNase and induces macrophages apoptosis. Recently, we demonstrated the *in vivo* expression of MAG\_5040, the SNase homologue of *M. agalactiae*. We speculate that MAG\_5040 might also be an important virulence factor of mycoplasmas.

**Objectives**

Main goal of this study is to investigate the interaction of *M. agalactiae* with NETs and to verify if MAG\_5040, similarly to its *S. aureus* homologue, allows *M. agalactiae* to avoid NETs -mediated neutrophils extracellular killing.

**Methods**

Sheep neutrophils, either untreated or activated with PMA and/or MAG\_5040, were incubated with *M. agalactiae*. After 3 hours, extracellular DNA was stained with SYTOX Orange and images were detected with a confocal microscope. Differences in fluorescence intensity were also calculated.

**Conclusions**

Data suggest that *M. agalactiae* is able to induce NETs formation and their digestion *ex vivo*, suggesting a novel mechanism for escaping sheep innate immune response.

**Veterinary microbiology**

**PERSISTENT CONTAMINATION OF SMALL AND MEDIUM SIZED POULTRY FARM ENVIRONMENTS BY CLOSTRIDIUM PERFRINGENS IN THE UNITED KINGDOM**

J. Brown<sup>1</sup>, F. Frend<sup>1</sup>, R. Dixon<sup>1</sup>

<sup>1</sup>School of Life Sciences, University of Lincoln, Lincoln, United Kingdom

**Background**

*Clostridium perfringens* is a cause for increasing concern due to its involvement in severe infections in both humans and animals, especially poultry. Although *C. perfringens* is part of the natural microbiota of the intestinal tract in poultry, it is an opportunistic bacterium which can be pathogenic resulting in the possibly severe disease - necrotic enteritis.

**Objectives**

The aim of the present study was to determine the occurrence of *C. perfringens* on one single sampling occasion from poultry enterprises widely distributed across the United Kingdom. The samples were toxin genotyped by PCR and analysed by PFGE and antimicrobial testing

**Methods**

172 samples were collected from 50 poultry establishments described as 'free range' operations. None of the enterprises either prior or during the study reported necrotic enteritis in their poultry. Samples for bacterial isolation were grown on tryptose sulphite cycloserine (TSC) agar and quantified; typical colonies of *C. perfringens* putatively identified and confirmed biochemically. The samples were subjected to toxin production identification, ribosome typing, PFGE and antibiotic susceptibility testing.

**Conclusions**

The presence of *cpa*, *cpb*, *etx*, *iA*, *cpb2*, *cpe*, and *NetB* toxin genes were determined by PCR. 89.7% *C. perfringens* isolates were classified as type A and the remaining 10.3% type C; no other toxin genes were identified. Quantitative estimates of numbers of isolates was higher than expected (from 10<sup>4</sup> to 10<sup>9</sup> CFU/g) from poultry

farm sources, regardless of the cleaning protocol used to sanitise the housing environment. Attempts to correlate specific clusters of *C. perfringens* with specific locations will be presented.

**FEMS-1543**

**Veterinary microbiology**

## **MSSA AND MRSA CO-COLONIZATION DYNAMICS AND CLONAL DIVERSITY IN PIGS**

A. Fetsch<sup>1</sup>, U. Roesler<sup>2</sup>, B. Kraushaar<sup>1</sup>, A. Frieese<sup>2</sup>

<sup>1</sup>*Biological Safety, Federal Institute for Risk Assessment, Berlin, Germany*

<sup>2</sup>*Institute for Animal Hygiene and Environmental Health, Freie Universität Berlin, Berlin, Germany*

### **Background**

Methicillin-susceptible *Staphylococcus aureus* (MSSA) and methicillin-resistant *Staphylococcus aureus* (MRSA) are colonizers of skin and mucosa. Studies about MSSA and MRSA in human patients showed a competition of these two microorganisms for colonization space in the anterior nares. Moreover, in humans one clone can be found rather than differing types of MSSA and MRSA. At present, it is unknown whether this is also true for animals.

### **Objectives**

The aim of this study was to investigate the colonization dynamics of both MSSA and MRSA in pigs over a longer time period and investigate their clonal diversity. The results might be of interest for the development of control strategies. This is important as in farm animals, and particularly in pigs common MRSA are found that are transmissible to humans and the environment.

### **Methods**

Eighteen pigs were sampled three times every ten weeks with a nasal swab. Additionally, environmental samples were taken. All samples were investigated for MSSA and MRSA, respectively. Spa-typing was done with up to five MRSA and MSSA isolates, respectively, found per sample and time point. Of almost 400 MSSA and MRSA isolated, 62 isolates were further investigated by microarray.

### **Conclusions**

The results do not support the hypothesis of a competitive colonization of MSSA and MRSA in the anterior nares of pigs. Rather we found a changing status. Hence, highly identical clones of MSSA and MRSA are present in the anterior nares of pigs and their environment. CC398 and CC9 associated spa-types were the predominating clonal lineages found among MRSA and MSSA isolates, respectively.

**FEMS-1351**

**Veterinary microbiology**

## **VAGINAL BACTERIOLOGY RESULTS OF THE EWES INDUCED WITH DIFFERENT PARTURITION INDUCTION METHODS**

G. GONCAGÜL<sup>1</sup>, E.S. ÖZDEMİR SALCI<sup>2</sup>

<sup>1</sup>MENNAN PAŞINLI VOCATIONAL HIGH SCHOOL, ULUDAG UNIVERSITY, BURSA, Turkey

<sup>2</sup>DEPARTMENT OF OBSTETRICS AND GYNAECOLOGY FACULTY OF VETERINARY MEDICINE, ULUDAG UNIVERSITY, BURSA, Turkey

### **Background**

Induction of parturition can result in some infective postpartum vaginal complications in ewes due to their side effects on parturition. Therefore, it is important to reveal whether induction methods responsible to the vaginal bacterial changing in ewes.

### **Objectives**

This study aims to reveal vaginal bacteriology and antibiogram results of the ewes induced with different parturition induction methods.

### **Methods**

Twenty-four curly-fleeced ewes (n=24) at 3rd pregnancy period on 138th day were divided as group I (n=6): control; group II (n=6): dexamethasone (16 mg, im); group III (n=6): aglepristone (5mg/kg, im) and group IV (n=6): dexamethasone (8mg, im) + aglepristone (2.5 mg/kg, im). For bacteriological examination, the vaginal swaps were taken from ewes at 138th pregnancy day and then they were induced as below. Parturitions had not any clinical complications. Vaginal swaps were repeated on days of postpartum 15 and 30. Bacterial identifications revealed that *Escherichia coli* was the dominant pathogen bacteria both pre-induction and postpartum days in all groups. In postpartum 15<sup>th</sup> day, *Acinetobacter* spp. was the other pathogens for only in group III. And in postpartum 30<sup>th</sup> day, *Acinetobacter baumannii* was the other pathogen in group III. Antibiotic susceptibility of these pathogens was performed by Kirby Bauer disc diffusion methods. *Escherichia coli* and *Acinetobacter baumannii* were 100.0% sensitive to enrofloxacin, *Acinetobacter* spp. was 100.0% sensitive to trimethoprim / sulfamethoxazole.

### **Conclusions**

It has been considered that induction of parturition can affect the vaginal flora and can be responsible for the postpartum vaginal complications to be encountered.

FEMS-2576

Veterinary microbiology

## CHARACTERISTICS AND ANTIMICROBIAL SUSCEPTIBILITY OF TRUEPERELLA PYOGENES ISOLATED FROM BOVINE MASTITIS CASES IN CHINA

D. Han<sup>1</sup>, A. rashad<sup>1</sup>, W. Chen<sup>1</sup>, G. Liu<sup>1</sup>, Y. Liu<sup>1</sup>, Z. Deng<sup>1</sup>, O. Szencs<sup>2</sup>, C. Bajcsy<sup>2</sup>,  
B. Han<sup>1</sup>

<sup>1</sup>College of Veterinary Medicine, China Agricultural University, Beijing, China

<sup>2</sup>Faculty of Veterinary Sciences, Szent István University, Üllő – Dóra major, Hungary

### Background

*Trueperella (T) pyogenes* is an opportunistic pathogen causes suppurative diseases in dairy cows. However, the pathogenesis and antibiotics resistance of *T. pyogenes* are still unclear.

### Objectives

*T. pyogenes* isolates morphological characteristics, the presence of genes (*plo*, *cbpA*, *fimA*, *fimC*, *fimE*, *fimG*, *nanH*, *nanP*, *tetW*, *ermX*, *ermB*), biofilm formation, the cytopathological effects in intracellular assay and antimicrobial resistance were investigated.

### Methods

*T. pyogenes* was isolated from 50 out of 275 clinical and subclinical bovine mastitis cases in China. Both pyolysin (*plo*) and collagen-binding protein (*cbpA*) virulence factor genes were detected by conventional PCR in all *T. pyogenes* isolates. The tissue culture plate method was used to assay the capacity of *T. pyogenes* for biofilm formation and showed that 90% of *T. pyogenes* isolates were able to form biofilms with different production amount. Minimum inhibitory concentrations (MICs) of 14 antimicrobial agents were determined and observed high susceptibility to rifampin (96%), while high resistance to trimethoprim–sulfamethoxazole (90%) and bacitracin (98%). Intracellular assay revealed that 4 different *T. pyogenes* isolates had different cytopathological effects on infected bovine mammary gland epithelial cells.

### Conclusions

18% *T. pyogenes* isolates indicates that *T. pyogenes* is important contributors to bovine mastitis. Moreover, the within-host quantitative, spatial, high occurrence of multidrug-resistant, biofilm producing and temporal dynamics of *T. pyogenes* interactions are key factors to better understand how immunity acts on infections with bacteria and how they evade immune surveillance; thus, highlighting the need for prudent use of antimicrobial agents in veterinary medicine (This research was supported by projects No. 2012BAD12B03, No. 313054, No. 20120008110042, No. 2014M561102 and No. GDT20141100043).

### **BRUCELLOSIS IN GREY SEAL IN BALTIC SEA**

V. Hirvelä-Koski<sup>1</sup>, V. Hirvelä-Koski<sup>1</sup>, P. Heikkinen<sup>1</sup>, M. Isomursu<sup>1</sup>, M. Nylund<sup>1</sup>,  
T. Skrzypczak<sup>2</sup>

<sup>1</sup>Research and Laboratory Department, Finnish Food Safety Authority Evira, Oulu, Finland

<sup>2</sup>Research and Laboratory Department, Finnish Food Safety Authority Evira, Helsinki, Finland

### **Background**

Finnish Food Safety Authority Evira participates in the HELCOM monitoring program to assess the health status of seals in the Baltic Sea area. Organ samples are collected from hunted seals or, to a lesser extent, from seals found dead. In the year 2013 we detected for the first time brucellosis in one of these samples. There are two marine *Brucella* species, *B. pinnipedialis* affecting pinnipeds (sea lions, walrus and true seals) and *B. ceti* affecting cetaceans (dolphins, porpoises and whales). Brucellosis is a zoonosis.

### **Objectives**

The aim of this study was to examine the distribution and possible infection routes of brucellosis in grey seals in the northern Baltic Sea.

### **Methods**

Livers of grey seals (*Halichoerus grypus*) (n=95) were inspected for parasites and pathological lesions. Samples for bacteriological examination (n=18) were taken from livers with macroscopic inflammatory lesions (n=10) and from normal livers (n=8) for control and cultivated on fastidious anaerobe agar plates. The plates were incubated at 37 °C in microaerophilic atmosphere, and observed for bacterial growth daily for 10 d. The identification was based on Stamp stain, biochemical tests and PCR.

### **Conclusions**

Brucellosis does not seem to be rare in grey seals in the northern Baltic Sea. Of 10 samples with lesions 3 were positive. All normal livers were negative. The bile ducts of positive livers contained abundant numbers of flukes (*Pseudamphistomum truncatum*), which were positive for *Brucella* sp. in PCR. Flukes might be one of the possible vectors of brucellosis in marine environments.

**FEMS-1396**

**IDENTIFICATION AND GENETIC CHARACTERISATION OF OVINE  
PARATUBERCULOSIS IN SLAUGHTERED ANIMALS IN SHIRAZ-IRAN USING  
IS900 PCR**

K. Iraniparast<sup>1</sup>, M. Haghkhah<sup>1</sup>, S. Shekarforoush<sup>2</sup>, S. Hosseinzadeh<sup>2</sup>

<sup>1</sup>Pathobiology, school of Vet Med, Shiraz, Iran

<sup>2</sup>Food Microbiology, school of Vet Med, Shiraz, Iran

**Background**

*Mycobacterium avium* subspecies *paratuberculosis* (MAP) is an obligate, Gram positive, acid-fast bacterium which has adapted to the gastrointestinal tract of ruminants and other animals and can cause fatal inflammatory disorder called Johne's disease. The potency of microorganism to infect human and its close association with Crohn's disease is the main public health issue of the infection, worldwide.

**Objectives**

The aim of this study was to find out some information about the frequency of MAP in the slaughtered animals and further characterization of its genome, in Southern Iran.

**Methods**

The study was conducted between October 2013 to August 2014 in which total of 450 specimens from ileocecal lymph node, ileocecal valve and surfaces of 150 slaughtered sheep were collected. The animals were categorized according to the sex and age. IS900 PCR assay was employed to confirm the positive cases.

**Conclusions**

Out of 450 specimens, 12 were found positive using IS900 PCR assay. All the positive samples were from the intestinal tissues and lymph nodes. Statistical analysis of the results, using Fisher's Exact test, confirmed no significant difference between the frequency of infections in the ram and ewe. Furthermore, infection in the lambs was significantly lower than sheep over 1.5 year age. In general, employing the IS900 PCR assay is recommended to monitor the MAP infected carcasses. The sequence analysis of the positive cases showed a 93% identity when it was compared with gene bank database.

## **EAR INFECTIONS IN DOGS IN ICELAND. THE CAUSATIVE AGENTS AND THEIR SENSITIVITY TO ANTIBIOTICS**

G. Jonsdottir<sup>1</sup>, S. Bjarnadottir<sup>1</sup>, E. Benediktsdottir<sup>1</sup>, K. Matthiasdottir<sup>1</sup>,  
H. Valgeirsdottir<sup>1</sup>, A. Astvaldsson<sup>1</sup>, E. Gunnarsson<sup>1</sup>, V. Fridriksdottir<sup>1</sup>

<sup>1</sup>Bacteriology, Keldur - The Institute for Experimental Pathology University of Iceland, Reykjavík, Iceland

### **Background**

Ear infections are a common problem in dogs. The infections can be very persistent and difficult to treat. The common treatment is with antibiotics and in chronic infections the dogs go through multiple treatments.

### **Objectives**

The aim of this study was to map the most common causes of ear infections in dogs and test their resistance to antibiotics.

### **Methods**

In the period of 2010 to 2013 the Department of Microbiology received 246 samples from dogs for microbial culture. Of these 93 were ear samples and we managed to isolate pathogenic bacteria and/or fungi from 83 of dogs. In the study period the main cause of ear infections in dogs' ears was the bacterium *Staphylococcus intermedius*. In addition we commonly isolated *Proteus mirabilis*, *Pseudomonas aeruginosa* and *Candida spp*. The antibiotic sensitivity of the isolated pathogens varied considerably and we often saw multiresistant *Proteus mirabilis* and *Candida spp*.

### **Conclusions**

Dogs with ear infections are usually treated with antibiotics as soon as the infection is detected. Our study shows that multi-resistant bacteria are common in dogs with recurrent ear infections. It is very important to detect the pathogen and obtain information about antibiotic sensitivity before starting treatment. This will ensure more effective treatment and possibly prevent chronic ear infections caused by multiresistant bacteria.

**GENOTYPIC RELATEDNESS OF SALMONELLA ENTERICA SEROVAR ENTERITIDIS ISOLATES FROM CHICKENS AND HUMANS IN KOREA**

M. Kang<sup>1</sup>, J. Oh<sup>1</sup>, Y. Kwon<sup>1</sup>, O. Jeong<sup>1</sup>, S. Youn<sup>1</sup>, H. Kim<sup>1</sup>, I. Jang<sup>1</sup>, S. Jung<sup>1</sup>

<sup>1</sup>Avian Disease Division, Animal and Plant Quarantine Agency, Anyang, Korea

**Background**

*Salmonella enterica* serovar Enteritidis is one of the most common serotypes implicated in *Salmonella* infections in both humans and poultry worldwide. Most *Salmonella* infections in humans are considered to be associated with foods of animal origins contaminated by *Salmonella*. Indeed, the most common sources of *Salmonella* Enteritidis infection are believed to be chickens and chicken products.

**Objectives**

This study was to estimate the genetic relationship between *Salmonella* Enteritidis isolates from chickens and humans in South Korea.

**Methods**

A total of 127 chicken isolates were collected from clinical cases, on-farm feces, and slaughtered chicken meat between 1998 and 2012 and 20 human clinical isolates were obtained from patients who showed clinical signs between 2000 and 2006 in Korea. We compared pulsed-field gel electrophoresis (PFGE) patterns and multilocus variable-number tandem-repeat analysis (MLVA) profiles of the isolates.

**Conclusions**

PFGE analysis with all the isolates revealed 28 patterns and MLVA identified 16 allelic profiles. PFGE and MLVA showed common types shared by most human and chicken isolates although there was relatively poor congruence between the two analyses. Overall findings demonstrate the transmission of the serovar Enteritidis between humans and chickens.

**Veterinary microbiology**

## **DEVELOPMENT AND PERFORMANCE EVALUATION OF ENZYME LINKED IMMUNOSORBENT ASSAY AND LINEBLOT FOR SEROLOGICAL DIAGNOSIS OF LEISHMANIASIS IN DOGS**

A. Latz<sup>1</sup>

<sup>1</sup>R+D, NovaTec Immundiagnostica GmbH, Dietzenbach, Germany

### **Background**

Canine leishmaniasis is a zoonotic disease by the protozoan parasite *Leishmania* transmitted by the bite of an infected phlebotomine sandfly. *Leishmania infantum* is the most common and important cause of canine leishmaniasis worldwide. Other *Leishmania* spp. reported from dogs include *L. mexicana*, *L. donovani*, and *L. braziliensis*. Leishmaniasis can be categorized by two types of diseases in dogs: a cutaneous reaction and a visceral reaction also known as black fever, the most severe form of *leishmaniasis*.

Infection does not invariably lead to illness. In fact, most infected dogs remain asymptomatic and may never develop clinical manifestations. In endemic regions, the prevalence of disease is often less than 10% and only about 1 in 5 infected dogs are considered likely to develop clinical disease.

Diagnosis of canine leishmaniasis is based on the presence of clinical signs together with positive specific antibody assay.

### **Objectives**

The aim of this work was to develop a serological ELISA assay to detect IgG and IgM antibodies against *Leishmania* in serum or plasma samples derived from all mammals.

### **Methods**

Microtiterplates were coated with antigen preparations of *Leishmania infantum*. The presents of antibodies against *Leishmania* is detected by protein A/G-HRP. A sample collection of about 200 positive samples and 400 negative samples was used for development and evaluation of the assay.

## **Conclusions**

Here we show the performance characteristic of the newly developed assay. Due to the improved antigen design, purification method and test setup a superior assay performance was achieved compared to other test methods.

## **PREVALENCE OF BOVINE MASTITIS PATHOGENS AND ITS ANTIMICROBIAL RESISTANCE IN CHINA**

H. Li<sup>1</sup>, J. Luo<sup>1</sup>, X. Li<sup>1</sup>, F.E.N.G. Yang<sup>1</sup>, X. Wang<sup>1</sup>

<sup>1</sup>Veterinary laboratory,

Lanzhou institute of husbandry and pharmaceutical Sciences Chinese Academy of Agricultural Sciences, Lanzhou, China

### **Background**

Bovine mastitis was one of the common and frequent disease in cows, caused huge economic losses to dairy industry.

### **Objectives**

The objective of this study was to investigate the distribution of bovine mastitis pathogens and their antibiotic resistance in China.

### **Methods**

A total of 3941 milk samples from clinical mastitis cows (n=963), subclinical mastitis cows (n=2772) and healthy cows (n=206), which were collected from 40 cities in 150 dairy farms in China. Bacteria were isolated and identified. And disc diffusion test (K-B method) was used to determine the antibiotic resistance of the main pathogens, including *Streptococcus agalactiae*, *Streptococcus dysgalactiae*, *Staphylococcus aureus* and *Escherichia coli*.

### **Conclusions**

The results showed that 24 species of bacteria and fungi include 4337 microorganisms were isolated from 3445 milk samples (87.41%), the other 496 milk samples were detected as negative ones. A total of 2386 bacteria were identified as bovine mastitis related pathogens: *Streptococcus agalactiae* (35.54%), *Streptococcus dysgalactiae* (23.55%), *Staphylococcus aureus* (16.89%), *Escherichia coli* (12.99%), *Streptococcus* (5.28%), *Klebsiella* (1.63%), *Proteus* (1.59%), *Pseudomonas aeruginosa* (1.22%), *Stellate Nocardia* (0.59%), *Suppurative Corynebacterium* (0.38%), *Candida albicans* (0.17%) and *Streptococcus pyogenes* (0.17%). The total pathogens detection rate was 62.12%. Drug susceptibility test showed that the four major pathogens have different resistance to all antibiotics, the resistance rate was 10%~100%. Especially to penicillin G, streptomycin, and cotrimoxazole respectively, the resistance rate was 30%~100%.

## **O SEROGROUPS OF ENTEROPATHOGENIC (EPEC) AND SHIGATOXIGENIC (STEC) ESCHERICHIA COLI FROM**

*I. Fakih<sup>1</sup>, J.N. Duprez<sup>1</sup>, D. Thiry<sup>1</sup>, L. Jouant<sup>1</sup>, A. Iguchi<sup>2</sup>, M. Saulmont<sup>3</sup>, J. MAINIL<sup>1</sup>*

<sup>1</sup>*Infectious Diseases Bacteriology, FARAH and Faculty of Veterinary Medicine, LIEGE-SART TILMAN, Belgium*

<sup>2</sup>*Animal and Grassland Sciences, Faculty of Agriculture UOM, MIYAZAKI, Japan*

<sup>3</sup>*Bacteriology, Association Régionale de Santé et d'Identification Animale, CINEY, Belgium*

### **Background**

*Escherichia coli* producing the attachment-effacement (AE) lesion (EPEC) and/or Shiga toxins (STEC) cause enteritis and (bloody) diarrhoea in young calves and in humans, and are also present in the intestines of healthy cattle. Besides the O157:H7 serotype, EPEC and STEC can belong to more than sixty O serogroups. Of them, 8 have been most frequently identified worldwide: O5, O26, O103, O111, O118, O121, O145 and O165, with some also causing diarrhoea in young calves.

### **Objectives**

This study aimed at identifying the pathotypes and the O serogroups of STEC and EPEC isolated from <1-month-old diarrhoeic calves in Wallonia, Belgium.

### **Methods**

(i) 233 enterohaemolysin-producing *E. coli* were isolated at ARSIA between November 2008 and February 2014 from diarrhoeic calves after growth on EHLY Medium®. They were tested with a triplex PCR targeting the *stx1*, *stx2* (Shiga toxins) and *eae* (AE lesion) genes.

(ii) triplex PCR-positive *E. coli* were assayed with two pentaplex PCR targeting the specific genes coding for the nine O serogroups listed above and for the O104 serogroup.

### **Conclusions**

(i) 206 isolates tested positive with the triplex PCR. The most frequent pathotypes were *eae+stx1+* (102 isolates), *eae+* (78 isolates) and *eae+stx1+stx2+* (13 isolates).

(ii) the most frequent serogroups of EPEC and STEC were O26 (57 isolates) and O111 (36 isolates). A few additional isolates tested positive for the O103, O5, O145, O121 and O157 serogroups.

(iii) the future is to compare these EPEC and STEC with those isolated from healthy cattle and from humans, to identify host- and age-specific properties.

**COMPARISON OF BACTERIOLOGICAL AND GENETIC IDENTIFICATION OF MAMMARY PATHOGENS IN MILK SAMPLES FROM COWS WITH CHRONIC MASTITIS IN WALLONIA, BELGIUM**

C. Ngassam-Tchamba<sup>1</sup>, A.S. Rao<sup>2</sup>, J.N. Duprez<sup>1</sup>, D. Thiry<sup>1</sup>, C. Hanzen<sup>2</sup>, L. Theron<sup>2</sup>,  
J. MAINIL<sup>1</sup>

<sup>1</sup>Infectious Diseases Bacteriology, FARAH and Faculty of Veterinary Medicine, LIEGE-SART TILMAN, Belgium

<sup>2</sup>Farm Animals Obstetrics, FARAH and Faculty of Veterinary Medicine, LIEGE-SART TILMAN, Belgium

**Background**

Mastitis is the inflammation of the mammary gland following infection by most often bacteria. Clinical mastitis is characterized by macroscopic modification of the milk while only high cell counts observed during subclinical mastitis. According to the bacterial species, mastitis can also be subdivided as either contagious (*Staphylococcus aureus*, *Streptococcus agalactiae*, *Mycoplasma bovis*, coagulase-negative staphylococci, *Corynebacterium* sp., etc) or environmental (*Escherichia coli* and coliforms, *Streptococcus uberis*, *Streptococcus dysgalactiae*, *Enterococcus* sp., etc).

**Objectives**

The overall objective of this study is to compare the results of detection of mastitis-associated bacteria by classical bacteriology and by quantitative (q) PCR.

**Methods**

A total of 120 milk samples were collected from mammary gland quarters with high cell counts (> 300.000 Somatic Cell) between January and March 2014 in seven farms in Wallonia. Samples were inoculated onto Columbia 5% sheep blood, McConkey's, Chapman's and modified Edwards' agar plates. Isolated colonies were picked up and stored at -80°C till further use. After new growth, colonies were Gram stained and identified using appropriate API sets.

**Conclusions**

A total of 231 isolates grew on Columbia blood agar. Of them, 133 isolates also grew on Chapman's agar including 63 *S. aureus* and 63 CNS; 70 isolates on Edwards' agar including 14 *S. agalactiae*, 12 *S. uberis*, 6 *S. dysgalactiae* and 10 *Enterococcus* sp.; and 15 isolates on McConkey's agar including 3 *E. coli*, 3 *Klebsiella* sp. and 8 *Pantoea* sp. These results are being compared with the results of the qPCR detection assay.

**DIVERSITY OF STAPHYLOCOCCUS SPECIES, ANTIMICROBIAL SUSCEPTIBILITY AND PREVALENCE OF ENTEROTOXIN GENES AMONG ISOLATES FROM CLINICAL MASTITIS IN KOSOVO**

*I. Mehmeti<sup>1</sup>, B. Behluli<sup>1</sup>, M. Mestani<sup>1</sup>, A. Adem<sup>2</sup>, D. Diep<sup>2</sup>, I. Nes<sup>2</sup>*

<sup>1</sup>*Faculty of Agriculture and Veterinary, University of Prishtina "HASAN PRISHTINA", Prishtina, Kosovo*

<sup>2</sup>*Norwegian University of Life Sciences, N1430, Aas, Norway*

**Background**

Mastitis is one of the most frequent and costly disease in dairy cattle caused by different bacteria.

**Objectives**

The purpose of this study was to determine and compare the prevalence of different staphylococci, their antimicrobial susceptibility and toxin production, obtained from mammary infected cows in Kosovo.

**Methods**

Total 152 cow's samples with clinical mastitis were collected. Cows were of different breeds and different lactation. Eight different commonly used antibiotics were analyzed for antimicrobial activity against staphylococci while SET-RPLA kit for enterotoxin detection.

**Conclusions**

Our results showed that, staphylococci were present in 89 out of 154 cows from which 58 were coagulase negative and 31 coagulase positive. *S. aureus* was most dominant (27/89) followed by *S. epidermidis* (25/89) and *S. chromogenes* (15/89). Interestingly, staphylococci were found more frequent in some dairy cow breeds than others. Most of the strains (76/89) were resistant to two or more different antibiotics. The highest resistance was observed against penicillin and ampicillin (>65%). While the lowest resistance was against erythromycin (<3%). Regarding the enterotoxin production, 40 out of the 89 strains produced at least one of the toxin types with SEA and SEC being the most common. In Kosovo is very common antibiotic misuse because of lack of local laboratories, hence the study suggests that, the uncontrolled use of antibiotics in treatment of different infective diseases might cause resistance against many antimicrobials. Therefore, attention should be paid on selection of antibiotics; timing of treatment, dosage and the uncontrolled and careless use of antibiotics should be more strictly regulated.

**Veterinary microbiology**

## **MALDI-TOF AS A TOOL IN IDENTIFICATION OF AVIAN MYCOPLASMA SPECIES**

T. Michiels<sup>1</sup>, P. Butaye<sup>2</sup>

<sup>1</sup>General bacteriology and antibiotic resistance, CODA-CERVA, Ukkel, Belgium

<sup>2</sup>Pathology bacteriology and avian diseases, Faculty of Veterinary medicine, Ghent, Belgium

### **Background**

MALDI-TOF is a key method in identification of microorganisms. Large databases of reference and field strains have been made commercially available.

Identifying *Mycoplasma* species has always been a time-consuming process using serological tests and molecular methods which require a large number of primers.

### **Objectives**

Presently, only 3 avian *Mycoplasma* species are available in commercial databases. To evaluate if MALDI-TOF is a useful tool, first a larger database needed to be constructed. Secondly, strains isolated from infected birds were compared and matched against the database.

### **Methods**

Fourteen reference and 8 field strains, obtained from collections held at our facility and from the University of Liverpool were grown in broth. An ethanol/formic acid extraction method was performed on each strain and then spotted on a MALDI target plate. For each strain, minimum 20 mass spectra of high quality were acquired to create the MSP using MALDI Biotyper 3.1 software.

Forty-nine clinical isolates from poultry and wild birds were matched. Twenty-seven were correctly identified with a matching score of  $\geq 2.0$ , 6 with a score between  $\geq 1.7$ -1.99 and 16 remained unidentified.

### **Conclusions**

MALDI-TOF is a rapid and useful tool in identifying *Mycoplasma* species. Fourteen isolates did not match probably due to missing strains in the database or possible unknown *Mycoplasma* species. More clinical isolates will be tested in the future and all non-identified isolates will be verified with 16S sequencing.

### **Acknowledgments**

This study was funded by the Federal Public Service of Health, Food Chain Safety and Environment (RT12/4 Mycoplasma)

## **IN VITRO ACTIVITY OF CONVENTIONAL DRUGS AND NATURAL ESSENCES AGAINST PROTOTHECA**

S. Morandi<sup>1</sup>, T. Silvetti<sup>1</sup>, P. Cremonesi<sup>2</sup>, M. Brasca<sup>1</sup>

<sup>1</sup>*Institute of Sciences of Food Production, National Research Council, Milan, Italy*

<sup>2</sup>*Institute of Agricultural Biology and Biotechnology, National Research Council, Milan, Italy*

### **Background**

Bovine mastitis caused by *Prototheca* can assume high significance because of economic losses and the potential risk to public health. Many studies highlighted the high level of antibiotic resistance of *Prototheca*, as well as the unsuccessful therapies.

### **Objectives**

To determine the *in vitro* susceptibility of *Prototheca* isolates to different antibiotics and alternative treatments based on essential oils.

### **Methods**

Sixteen isolates of *Prototheca* were identified by multiplex PCR reaction, typed using RAPD-PCR, and tested by the disk diffusion method for their susceptibility to 28 antibiotics. The efficacy tests to essential oils (thymol, carvacrol and cinnamaldehyde) were performed using emitters releasing compounds in a controlled way in jars, containing the *Prototheca* strains streaked on Sabouraud agar.

### **Conclusions**

All the strains were resistant to Amikacin, Ampicilin, Aztreonam, Cefepime, Ceftazidime, Chloramphenicol, Ciprofloxacin, Erythromycin, Fosfomicin, Imipenem, Levofloxacin, Meropenem, Mupirocin, Nitrofurantoin, Oxacillin, Penicilin G, Piperacillin, Quinupristin/Dalfopristin, Rinfamicin, Streptomycin, Tetracycline, Ticarcillin/clavulanic acid, Tobramycin and Vancomycin. In contrast, Colistin sulphate, Gentamicin, Kanamycin and Netilmicin were effective against all the strains tested.

The growth of *P. zopfii* genotype 1- 2, and *P. blasckea* was completely inhibited by thymol, carvacrol and cinnamaldehyde.

The results of the study revealed 4 out of 28 antibiotics tested efficient against *Prototheca* spp. while all the strains were inhibited by the tested essential oils.

Thus, *in vivo* studies are needed to evaluate if these compounds could rise as alternative treatments for bovine mastitis caused by *Prototheca* spp.

## **CHARACTERIZATION OF VIRULENCE FACTORS AND IMMUNE-STIMULATING ANTIGENS IN *VIBRIO SALMONICIDA***

S.F. Nørstebø<sup>1</sup>, M.V. Wade<sup>2</sup>, A.M. Bjelland<sup>1</sup>, P.M. Fidopiastis<sup>2</sup>, H. Sørum<sup>1</sup>

<sup>1</sup>Food Safety and Infection Biology, Norwegian University of Life Sciences, Oslo, Norway

<sup>2</sup>Center for Coastal Marine Sciences, California Polytechnic State University, San Luis Obispo, USA

### **Background**

*Vibrio salmonicida* is the cause of cold-water vibriosis in farmed Atlantic salmon. The disease manifests as a hemorrhagic septicemia, with a mortality ranging from 3-90 %. In the 1980s, the disease was a major challenge to the Norwegian aquaculture industry, but it is now being effectively controlled by the use of oil-based vaccines. Nevertheless, in recent years there have been some reports of disease outbreaks. In 2013, 13 Norwegian fish farms were diagnosed with cold-water vibriosis, all localized in the three northernmost counties of Norway.

### **Objectives**

The knowledge on virulence factors of *Vibrio salmonicida* and the subsequent immune response of the fish is limited. As bacteria adapt to their current environment, a bacterium isolated from a diseased fish will not be identical to the same species cultivated *in vitro*. The aim of this study was to explore the phenotype of bacteria present *in vivo*.

### **Methods**

We have grown *Vibrio salmonicida* in semi-permeable implants in live fish and analyzed bacterial protein expression by two-dimensional gel electrophoresis and tandem mass spectrometry. The experiment was approved by the Norwegian Animal Research Authority (approval no. ID6228).

### **Conclusions**

Our findings may contribute to the knowledge on disease progression in cold-water vibriosis, as well as to provide novel targets for more effective vaccines. Also, the

study may provide insights in the course of disease for other bacterial infections in fish.

**FEMS-0968**

**Veterinary microbiology**

## **IDENTIFICATION AND TYPING OF LACTOCOCCUS GARVIEAE BASED ON MALDI TOF MS**

M. Pérez-Sancho<sup>1</sup>, A. Casamayor<sup>2</sup>, E. Pulido<sup>2</sup>, J.F. Fernández-Garayzabal<sup>2</sup>,  
L. Domínguez<sup>2</sup>, A.I. Vela<sup>2</sup>

<sup>1</sup>Campus CEI Moncloa-Centro Visavet, Universidad Complutense de Madrid, Madrid, Spain

<sup>2</sup>Centro Visavet, Universidad Complutense de Madrid, Madrid, Spain

### **Background**

MALDI-TOF-mass spectrometry (MS) has emerged as a powerful technique for the routine identification of microorganisms in clinical microbiology laboratories allowing an easier and faster diagnosis than conventional phenotypic and molecular methods. We have evaluated the suitability of MALDI-TOF for the rapid identification of *Lactococcus garvieae* the etiological agent of lactococcosis, a septicemic infection affecting different wild and farmed fish species, and recognized also as an opportunistic emerging human pathogen.

### **Objectives**

Assessment of the reliability of MALDI-TOF MS for the identification of *Lactococcus garvieae*

### **Methods**

A total of 35 isolates from different host and environments were obtained from the culture collection of VISAVET were used in the study. The identification results obtained by MALDI TOF were compared with those obtained by biochemical identification (API 32 Strep) and by a species- specific PCR assay (Zlotkin et al. 1998. J Clin Microbiol 36, 983-985). Mass spectra acquisition and analysis was performed on a Bruker UltraFlex platform (Bruker Daltonics) using MALDI Biotyper™ 3.0 software in the automatic mode using a matrix of saturated solution of  $\alpha$ -HCCA. In addition, a subset of isolates was subjected to PFGE.

### **Conclusions**

The majority of peaks were obtained in the range from m/z 2000 to 10000. The proteomic results matched with those of genotypic approach. Our results also showed some differences in MS spectra in *L. garvieae* isolates recovered from different origins/hosts suggesting the possible identification of molecular biomarkers for *L. garvieae*. Our study demonstrates that proteomics identification using MALDI TOF MS could be a reliable approach for identifying and discriminating this microorganism.

**IDENTIFICATION OF ARCANOBACTERIUM PLURANIMALIUM BY MALDI-TOF MS, BY SEQUENCING 16S RDNA AND GENE PLA AND BY DEVELOPMENT OF A LOOP-MEDIATED ISOTHERMAL AMPLIFICATION (LAMP) ASSAY**

O. Sammra<sup>1</sup>, J. Wickhorst<sup>1</sup>, C. Lämmle<sup>1</sup>, J. Alber<sup>1</sup>, M. Erhard<sup>2</sup>, A. Abdulmawjood<sup>3</sup>

<sup>1</sup>Pharmakologie und Toxikologie, Justus-Liebig-Universität, Giessen, Germany

<sup>2</sup>Diagnostic, RIPAC-LABOR GmbH, Postdam-Golm, Germany

<sup>3</sup>Institut für Lebensmittelqualität und -sicherheit,  
Stiftung Tierärztliche Hochschule Hannover, Hannover, Germany

**Background**

Genus *Arcanobacterium* consists of four species namely *A. pluranimalium*, *A. haemolyticum*, *A. phocae* and *A. hippocoleae*. More recently, *A. canis* and *A. phocisimile* were described as novel species. *A. pluranimalium* was initially recovered from a harbour porpoise and a fallow deer, from a dog with pyoderma, from abortion material, semen, abscesses, viscera, navel illness and peritonitis of sheep and from milk samples of cows with mastitis. More recently, an *A. pluranimalium* strain was recovered following necropsy of a juvenile giraffe. However, the clinical importance of *A. pluranimalium* in animal infection remains unclear.

**Objectives**

Because of this widespread presence of *A. pluranimalium* in clinical samples of various animals there is an urgent need of phenotypic and genotypic tests for a rapid and reliable identification of this bacterial species.

**Methods**

The *A. pluranimalium* strains investigated in the present study were analysed phenotypically, by MALDI-TOF MS analysis and by 16S rDNA sequencing. In addition, the previously sequenced gene *pla* encoding pluranimaliumlysin of *A. pluranimalium* was used for molecular identification of this bacterial species and for the development of oligonucleotide primers for a loop-mediated isothermal amplification (LAMP) assay.

**Conclusions**

Phenotypic methods, MALDI-TOF MS analysis, sequencing 16S rDNA and target gene *pla* and the newly designed *pla* LAMP assay of the present study allowed the identification of all nine investigated *A. pluranimalium* strains of ovine and bovine

origin and from a juvenile giraffe. This phenotypic and genotypic approach might help to elucidate the role this species plays in animal infections.

## **SEQUENCING AND PHYLOGENETIC ANALYSIS OF GP51 GENE OF BOVINE LEUKEMIA VIRUS ISOLATES IN KOREA IN 2014**

*H. Joung<sup>1</sup>, E. Kim<sup>1</sup>, E. Lee<sup>1</sup>, B. Kim<sup>1</sup>, S. Cho<sup>1</sup>, J. Song<sup>1</sup>, Y. SHIN<sup>1</sup>*

*<sup>1</sup>Viral Disease Division, Animal and Plant Quarantine Agency, Anyang, Korea*

### **Background**

Enzootic bovine leucosis was first reported by serological method in Korea as early as in 1980s and recent prevalence in dairy cattle was over 50%. So far there has been no report on the bovine leukemia virus (BLV) genotype circulating in Korea since partial *env* gene sequence which belonged to genotype 1 was deposited in 2009.

### **Objectives**

This study was performed to identify the genetic diversity of BLV in Korea.

### **Methods**

Total 185 whole blood samples were collected from dairy cattle in two farms in southeast region in Korea. BLV gp51 genes were amplified for diagnosis as described previously by Fechner et al. Gp51 full gene (903bp) for sequencing was amplified. The gp51 PCR products were purified, sequenced and analyzed using DNASTar program and Mega 6 Program.

### **Conclusions**

Total 185 samples were analyzed with PCR, and total 78 samples were positive for BLV *env* DNA nested PCR (37 samples out of 119 in farm A and 41 out of 66 in farm B). Further PCR reaction to amplify full gp51 gene was performed. 19 out of 37 positive samples from farm A and 31 out of 41 positive samples from farm B were amplified successfully. The genotype of sequences from farm A was divided into two types, genotype 1 and genotype 3. All 31 isolates from farm B were found to belong to genotype 1. This is the first report of BLV genotype 3 circulation in Korea.

**DEVELOPMENT OF COMPETITIVE ELISA FOR THE DETECTION OF ANTIBODIES AGAINST SEVERE FEVER WITH THROMBOCYTOPENIA SYNDROME VIRUS (SFTSV) IN SUSCEPTIBLE ANIMALS**

H. Lee<sup>1</sup>, E. Kim<sup>1</sup>, J. Song<sup>1</sup>, J. Cho<sup>2</sup>, J. Lee<sup>2</sup>, I. Cho<sup>2</sup>, Y. SHIN<sup>1</sup>

<sup>1</sup>*Viral Disease Division, Animal and Plant Quarantine Agency, Anyang, Korea*

<sup>2</sup>*Foreign Animal Disease Division, Animal and Plant Quarantine Agency, Anyang, Korea*

**Background**

The Severe Fever with Thrombocytopenia Syndrome (SFTS) caused by SFTS virus (SFTSV) which belongs to the *phlebovirus* in bunyaviridae family is an emerging tick-borne mediated infectious disease for human, and the fatality rate is 12% in China. SFTSV seems to have wide host range in that SFTSV positive ticks were isolated from farm animals and wild rodents. Therefore, it is important to monitor SFTSV positive animals to prevent circulation or transmission of SFTSV.

**Objectives**

As there is no gold standard method to detect SFTSV specific antibodies from field animals, we are developing competitive enzyme-linked immunosorbent assay (c-ELISA) technique using nucleocapsid protein (NP) of SFTSV.

**Methods**

The recombinant NP of SFTSV was obtained by the expression of cloned genes in *E. coli* and the SFTSV was amplified in Vero cells for 7 days. The purified recombinant protein or formalin-inactivated SFTSV was used to immunize laboratory animals. Mono- and polyclonal antibody were tested for their antigen specificity in immunofluorescence assay (IFA) and western blot.

**Conclusions**

We developed direct c-ELISA using SFTSV specific monoclonal antibody, and generated the SFTSV positive serum from immunized cattle. The c-ELISA result shows 98.08% agreement in IFA result using 418 cattle field serum samples. We also observed the cELISA is applicable to detect SFTSV positive sera from immunized cattle, chicken and goat. This technique could be usefully used as a serological diagnostic method for various species of SFTSV susceptible field animals.

**Veterinary microbiology**

## **PHYLOGENETIC ANALYSIS AND MOLECULAR CHARACTERIZATION OF MYCOPLASMA BOVIS OUTBREAK STRAINS IN DENMARK**

A. SHUKLA<sup>1</sup>, B. Kokotovic<sup>1</sup>

<sup>1</sup>Bacteriology Pathology and Parasitology, Technical University of Denmark, Frederiksberg C, Denmark

### **Background**

*Mycoplasma bovis* is a cattle pathogen causing broad spectrum of diseases including mastitis, pneumonia and arthritis. The infection is very difficult to control due to long-time persistence of the organism in asymptomatic carriers, lack of knowledge on the specific role of environmental factors in the development of clinical disease, poor response to antibiotic treatment and the lack of effective immunotherapy.

### **Objectives**

Here we report whole-genome sequence analysis of 41 *Mycoplasma bovis* isolates collected during recent outbreak of disease in Danish cattle herds. Our objectives were to determine the extent of genomic diversity in the test population, identify dominant clones, reconstruct their phylogenetic ancestry and infer transmission history.

### **Methods**

Genome sequencing was performed on an Ion Torrent PGM sequencer. Genomic libraries were prepared by using Ion Xpress Plus fragment library kit and amplified using Ion PGM Template 200 OT2 kit according to manufacturer's instruction. Raw sequence reads were pre-processed using FastQC, mapped to reference genome (PG45) using Burrows-Wheeler aligner and single nucleotide polymorphisms (SNPs) were identified using REALPHY server.

### **Conclusions**

Unique molecular markers were identified for individual strains. Phylogenetic clustering based on SNPs revealed two distinct clades indicating a recent common ancestry. Substantial variations in both the number and sequence identities of individual variable surface proteins were observed with respect to type strain PG45 that may have contributed to increased virulence. The genetic distances inferred from SNPs and temporal distances (sampling dates) showed a strong

negative correlation suggesting that introduction of strains into the herds took place much before sampling time.

<sup>2</sup>*Infection Biology, University of Liverpool & Wood Veterinary Group, Gloucester, United Kingdom*

<sup>3</sup>*Epidemiology and Population Health, Infection and Global Health, Wirral, United Kingdom*

### **Background**

Bovine digital dermatitis (BDD) and Contagious ovine digital dermatitis (CODD), are infectious foot diseases causing severe lameness in cattle and sheep, respectively. The causative agents of digital dermatitis (DD) in dairy cattle are considered to be *Treponema* bacteria, however little work has been done regarding DD in beef cattle. Similarly, although it is suggested CODD emerged from BDD little has been done to investigate the aetiology of the disease in sheep or the transmission of DD.

### **Objectives**

1. Isolate and characterise beef cattle and sheep DD treponemes from lesions and compare with dairy cattle DD treponemes.
2. Identify reservoirs of infection of DD.

### **Methods**

Beef cattle and sheep DD lesions were subjected to culture and PCR analysis for the commonly detected DD treponemes from dairy cattle lesions.

The gastrointestinal (GI) tract of beef cows and sheep was investigated as an infection reservoir of DD treponemes by analysing GI tract tissues for the presence of treponemes. Farm equipment which comes into contact with lesions was analysed by PCR and culture methods for the presence of treponemes.

### **Conclusions**

From 16S rRNA gene analysis, treponemes isolated from beef cattle and sheep lesions belonged to the groups of treponemes associated with dairy cattle lesions. The close similarity poses concerns for species-species transmission.

Several GI tract tissues were positive for DD treponemes, providing evidence towards the GI tract as an infection reservoir for DD treponemes. Additionally, farm equipment

was also found to harbour DD treponemes after coming into contact with an infected foot indicating a possible transmission route.

## **PROTECTING CHICKENS AGAINST CAMPYLOBACTER JEJUNI BY CAMELIDAE-DERIVED NANOBODIES**

C. Vanmarsenille<sup>1</sup>, J. Elseviers<sup>2</sup>, G.G. Hassanzadeh<sup>2</sup>, A. Martel<sup>3</sup>, F. Haesebrouck<sup>3</sup>, F. Pasmans<sup>3</sup>, J.P. Hernalsteens<sup>4</sup>, H. De Greve<sup>1</sup>

<sup>1</sup>VIB Laboratory of Structural and Molecular Microbiology, Vrije Universiteit Brussel, Brussels, Belgium

<sup>2</sup>VIB Nanobody Service Facility, Vrije Universiteit Brussel, Brussels, Belgium

<sup>3</sup>Department of Pathology Bacteriology and Avian diseases, Ghent University, Ghent, Belgium

<sup>4</sup>Genetische Virologie, Vrije Universiteit Brussel, Brussels, Belgium

### **Background**

*Campylobacter jejuni* is a Gram-negative microaerophilic bacterium, and is the major cause of human gastro-enteritis worldwide. It is a zoonotic pathogen and chickens are generally accepted as the most important source of infections. Since the use of antibiotics in animal feeds is no longer an acceptable option and the prevention is limited to hygiene measures, novel control methods are needed.

### **Objectives**

The purpose of this research is to investigate whether colonization of chickens by *C. jejuni* can be controlled by passive vaccination in a cost effective manner by using nanobodies, the antigen-binding domains of heavy-chain antibodies.

### **Methods**

Anti-*Campylobacter* nanobodies were identified after immunization of an alpaca with heat-killed *C. jejuni* cells. The binding of these nanobodies on different *C. jejuni* strains, isolated from chickens and their environment as well as human clinical isolates, was verified. Nanobodies that are able to bind all of the tested strains were selected for further research. We presumed that these nanobodies recognize conserved epitopes expressed on *C. jejuni*. The ability of one of these nanobodies to agglutinate *Campylobacter* cells was tested. This nanobody was multimerised by linking it to magnetic beads. The results confirm that the nanobody recognizes antigens on living *C. jejuni* cells and that multimers of this nanobody are able to agglutinate the *C. jejuni* cells.

### **Conclusions**

The nanobodies with a broad *Campylobacter* specificity can be interesting for diagnostic and therapeutic applications, such as for the reduction or inhibition of the colonization of chickens by *C. jejuni*.

## **GENETICS AND BIOFILM ANALYSIS ON STRAINS OF E.COLI ISOLATED FROM ANIMALS WITH DIARRHOEIC PROBLEMS.**

S. Migliore<sup>1</sup>, C. Piraino<sup>1</sup>, M. Goria<sup>2</sup>, M.G. Cusimano<sup>3</sup>, D. Schillaci<sup>3</sup>,  
V. Di Marco Lo Presti<sup>4</sup>, M. Vitale<sup>1</sup>

<sup>1</sup>Molecular Biology, Zooprofilattico Sperimentale of Sicily, Palermo, Italy

<sup>2</sup>Molecular Biology,

Zooprofilattico Sperimentale of Piedmont Liguria and Valle D'aosta, Turin, Italy

<sup>3</sup>Biological Chemical and Pharmaceutical Science and Technology (STEBICEF)., University of Palermo, Palermo, Italy

<sup>4</sup>Area Barcellona P.G., Zooprofilattico Sperimentale of Sicily, Palermo, Italy

### **Background**

- *Escherichia coli* (*E. coli*) is a bacterium that commonly lives in the intestines of people and animals. There are four major categories of diarrhoeogenic *E. coli*, namely: enterotoxigenic *E. coli* (ETEC), enteroinvasive *E. coli* (EIEC), enteropathogenic *E. coli* (EPEC) and enterohemorrhagic *E. coli* (EHEC). These categories of *E. coli* differ in their epidemiology and pathogenesis and their O: H serotypes and for the presence or absence of several genes responsible for their virulence.

### **Objectives**

- The objective of the study was the analysis of virulent genes and biofilm production in *E.coli* strains isolated from animals with diarrhoeic problems.

### **Methods**

The strains were isolated from stool samples of animals affected by diarrhoea. Genetic analysis were performed by multiplex PCRs. Biofilm assays were performed by safranin method with O.D. readings at 492 nm on 96 wells plate.

### **Conclusions**

The isolates were all coming from symptomatic animals from farms in which repeated episodes of diarrhoea are present. All isolates were negative for the *aggR* gene (Aggregative adherence fimbria), the *pet* gene (Plasmid-encoded toxin), *aap* (dispersin) and other genes. 10 out of 35 were positive for *irp2* (yersinia bactin biosynthesis gene) and 18 out of 35 strains carried the *astA* gene which encodes for EAST1 (Enteric Aggregative heat-Stable Toxin1). This protein is thought to play a role in EAEC pathogenicity even if not all EAEC strains harbour the *astA* gene. The analysis for biofilm formations on the first 22 isolates, showed low capability in biofilm formation. Only 8/22 showed values above 120 O.D., but further analysis will be performed with different stains.

**Veterinary microbiology**

## **DETERMINATION OF ANTIMICROBIAL RESISTANCE AND VIRULENCE GENES PATTERNS AMONG CAMPYLOBACTER FROM BOILERS IN POLAND**

K. Wieczorek<sup>1</sup>, J. Osek<sup>1</sup>

<sup>1</sup>Department of Hygiene of Food of Animal Origin,  
National Veterinary Research Institute, Pulawy, Poland

### **Background**

*Campylobacter* is the most common zoonotic agent deriving from broiler flocks and broiler carcasses in Poland. The increased resistance of this bacteria to antibiotics is a matter of special concern, representing a significant public health problem. The genetic features responsible for pathogenesis of campylobacteriosis are still under investigation.

### **Objectives**

The aims of the study were to test *Campylobacter* strains for antimicrobial resistance patterns and to screen for the presence of virulence-associated genes involved in different steps of infection.

### **Methods**

During the project, 29 broiler farms located in 15 voivodeships all over Poland were selected for sampling at the slaughterhouse level. In total, 252 isolates from caeca (150 *C. jejuni* and 102 *C. coli*) and 197 strains from the corresponding carcasses (142 *C. jejuni* and 55 *C. coli*) were tested. A microbroth dilution method was used to establish the antimicrobial resistance by the minimum inhibitory concentrations (MICs) to 7 antimicrobials. Additionally, the following genes: *cadF*, *flaA*, *virB11*, *iam*, *flhA*, *cdtA*, *cdtB*, *cdtC*, *ciaB*, *docA* and *wlaN* were detected by PCR.

### **Conclusions**

The most common resistance profile of *C. jejuni* was ciprofloxacin-nalidixic acid and tetracyclines. *C. coli* were mostly resistant to ciprofloxacin-nalidixic acid-tetracycline and streptomycin. The results regarding virulence patterns demonstrated that the majority of *C. jejuni* strains had virulence and cytotoxin gene pattern: *flaA*, *flhA*, *cadF*, *ciaB*, *cdtA*, *cdtB*, *cdtC* and *docA*. Among *C. coli*, the simultaneous presence of the *flaA*, *flhA*, *cadF*, *ciaB*, *cdtA*, *cdtB*, *iam* and *docA* markers was most often found.

**PRESENCE OF CAMPYLOBACTER JEJUNI IN DIFERENT SPECIES OF ANIMALS, POSSIBILITY OF ITS INFLUENCE AS A RESERVOIR AND/OR VECTOR INFECTION OF BROILERS**

S. Yubero Delgado<sup>1</sup>, S. Martínez Martínez<sup>1</sup>, C.B. Gutierrez Martín<sup>1</sup>, A. Alvarez-Estrada<sup>1</sup>, E.F. Rodríguez Ferri<sup>1</sup>

<sup>1</sup>Animal Health, University of León, Leon, Spain

**Background**

Campylobacteriosis is the most common foodborne gastroenteritis in industrialized countries and the number of cases is growing continuously. This bacterial infection is mainly related to the consumption of poultry meat, when it is contaminated by *Campilobacter jejuni*. Although it is a known fact that *C. jejuni* has a highly prevalent in broiler flocks, the source of infection in herds remains still unclear. Nowadays, it would be interesting to knowledge the role of the different animals in the transmission of the infection

**Objectives**

The objective of this research was to determine the prevalence of bacteria in different types of animal species

**Methods**

Both birds and mammals remaining in direct or indirect contact with infected broilers for *C. jejuni* were analyzed. Individual animals were sampled by rectal swab and all samples were processed similarly, being the positive samples confirmed by PCR. This organism was isolated from all species that had been in direct contact with infected broilers, but it cannot be isolated from the animals not having direct contact with them.

**Conclusions**

According to the results obtained, it is concluded that *C. jejuni* can be transmitted between different animal species, acting as vector and / or reservoirs of this organism in broilers.

key, Erzincan University, Erzincan, Turkey*

<sup>3</sup>*Department of Pathology, Dışkapı Training and Research Hospital, Ankara, Turkey*

**Background:** The possible relationship between human papillomavirus infection, tumor suppressor gene p53 and prostate cancer (PCa) has been previously investigated, however, the etiological role of HPV infection and p53 codon 72 polymorphism in the PCa pathogenesis remains highly controversial.

**Objectives:** The aim of the study was to assess the possible role of human papillomavirus in the development of prostate cancer and the distribution of the p53 codon 72 polymorphism in Turkish population.

**Methods:** We investigated the presence of HPV in 60 formalin fixed and paraffin embedded prostate cancer tissues, as well as in 36 benign prostatic hyperplasia tissue (BPH) samples by using real-time PCR and pyrosequencing. Furthermore, the same group of patients were also screened for the presence of the Arg72Pro polymorphism of the p53 gene, a p53 polymorphism related to HPV.

**Conclusions:** No HPV DNA was detected while using real-time PCR in any of the 36 BPH samples. One of the sixty (1.67%) PCa samples was found to be positive for HPV DNA by using a real-time PCR. After using pyrosequencing analysis, the only HPV type detected in the PCa sample was HPV-57. Compared to the control group, Arg /Pro genotype was observed more frequently in prostate cancer patients ( $p=0.044$ ), and also Pro allele frequency is higher in prostate cancer patients ( $p=0.021$ ). Our findings do not support the involvement of HPV in the etiology of prostate carcinogenesis, and the proline allele could be a risk factor for the development of prostate cancer in the Turkish population.

## **FACTORS AFFECTING MARINE MICROBIAL HOST-VIRUS INTERACTIONS**

C. Brussaard<sup>1</sup>

<sup>1</sup>*Biological Oceanography, Netherlands Institute for Sea Research (NIOZ), 't Horntje, Netherlands*

### **Background**

Viruses are the numerically dominant life forms on Earth. They represent a huge reservoir of genetic diversity, infecting organisms from small to large. In the oceans, every second  $10^{23}$  viral infections take place.

### **Objectives**

To fully comprehend the impact marine viruses can have on their host population dynamics and subsequently biodiversity, ecosystem functioning and global energy & matter fluxes, it is essential to study virus-host interactions under different environmental conditions.

### **Methods**

Here I will present experimental results on physiochemical variables affecting algal virus growth characteristics, as well as field data showing how a changing ocean due to global warming can control the magnitude of viral lysis as compared to the traditional loss factor, grazing.

### **Conclusions**

These examples illustrate the importance of environmental factors underlying the ecological importance of viral infection in marine ecosystems. Further research is warranted to identify more regulatory factors and understand the mechanisms by which they influence virus-host interactions.

**RECOMBINANT LIPIDATED DENGUE ENVELOPE PROTEIN DOMAIN III INDUCES DURABLE NEUTRALIZING ANTIBODY RESPONSES AND PROTECTIVE IMMUNITY**

H.W. Chen<sup>1</sup>, C.Y. Chiang<sup>1</sup>, C.H. Leng<sup>1</sup>, C.H. Hsieh<sup>1</sup>, J.P. Tsai<sup>1</sup>, M.Y. Chen<sup>1</sup>, H.H. Liu<sup>1</sup>, S.J. Liu<sup>1</sup>, P. Chong<sup>1</sup>

<sup>1</sup>National Institute of Infectious Diseases and Vaccinology,  
National Health Research Institutes, Miaoli, Taiwan

**Background**

The immunogen and immunopotentiator are two important components of vaccines. Combination of these two components into a single construct will have a great potential to increase the reactivity of immunogen. The lipid moiety of the recombinant lipoprotein provides a danger signal to activate antigen-presenting cells via toll-like receptor 2, which may further enhance immune responses.

**Objectives**

We selected dengue-4 envelope protein domain III (LD4ED III) as the immunogen and converted this candidate in lipidated form in *Escherichia coli*-based system. In the present study, the immunogenicity and protective immunity of LD4ED III in mice were evaluated.

**Methods**

Recombinant proteins were purified by immobilized metal affinity chromatograph columns. Groups of mice were immunized subcutaneously twice with 10 µg of D4ED III or LD4ED III in PBS at a 4-week interval. Mice immunized with PBS alone served as controls. Immune responses in mice were examined. All animal studies were approved and performed in compliance with the guidelines of the Animal Committee of the National Health Research Institutes.

**Conclusions**

The LD4ED III expressed in *E. coli* retains the proper conformation, which has the capability to compete with dengue virus for cellular binding sites. In addition, LD4ED III is more immunogenic than D4ED III to induce immune responses. Most importantly, LD4ED III elicits a durable neutralizing antibody response and inhibits viremia in LD4ED III vaccinated mice in the absence of exogenous adjuvant. These results suggest that lipidated dengue envelope protein domain IIIs are potential dengue vaccine candidates.

**Background**

Obesity which develops due to multifactorial reasons, was associated recently with human Adenovirus-36 (Ad-36).

**Objectives**

The aim of this study was to investigate the prevalence of Ad-36 antibodies in obese adults and also investigate the DNA of Ad-36 in their adipose tissue.

**Methods**

In this cross-sectional and case-control based study, 49 obese adults (BMI  $\geq 30$  kg/m<sup>2</sup>) and 49 non-obese adults (BMI  $\leq 25$  kg/m<sup>2</sup>) were included in this study as patient and control groups, respectively. Adipose tissue samples obtained by the lipoaspiration method, were studied by PCR methods. Simultaneously, the peresence of Ad-36 antibodies and serum leptin and adiponectin levels were assessed by serum neutralization assay (SNA) and ELISA, respectively.

## **Conclusions**

Ad-36 antibody was detected in 6 (12.2%) of 49 patients by SNA and was statistically significant ( $p < 0.05$ ). We couldn't detect Ad-36 DNA in adipose tissue; however, we detected significantly higher Ad-36 antibody levels in the obese group compared to the non-obese group. Mean BMI and leptin levels were higher in the Ad-36 positive group, while adiponectin levels were found to be lower in the Ad-36 positive group. Although no statistically significant difference was found in cholesterol and triglyceride levels between the two groups ( $p > 0.05$ ), lower mean serum cholesterol and triglyceride levels were found in the Ad-36 positive patients. There is a need for extended serial, particularly cohort and human-based, studies in order to have a clear understanding of the Ad-36-obesity relationship.

california state university of channel islands(CSUCI), california, USA*

*<sup>4</sup>School of Medicine, shahid beheshti university of medical sciences, Tehran, Iran*

### **Background**

Norovirus genogroup I (NV GI) and NV GII sapovirus (SaV) genogroups I, II, IV, and V, human rotavirus A(HRV), adenovirus serotypes 40 and 41 (AdV), and human astrovirus (AstV) are the most common causes of viral gastroenteritis and result in large outbreaks of viral diarrhea. An estimated 1.8 million children die each year from largely preventable enteric illnesses, with the large majority of these mortalities occurring in developing countries. Gastroenteritis is a major cause of morbidity and mortality in children worldwide.

### **Objectives**

Astroviruses are one of the major viral pathogens responsible for gastroenteritis. In this study performs to determine the prevalence of astrovirus in fecal specimens of children with gastroenteritis.

### **Methods**

In this study 2490 stool samples from children less than five years with gastroenteritis from five cities of Iran were collected. The prevalence of human astroviruses was tested in patients with acute gastroenteritis by using conventional duplex reverse transcription (RT) -PCR and electrophoresis.

### **Conclusions**

Young children were much more likely to be admitted with acute gastroenteritis. In this study astrovirus was detected in 1.6% of samples. There is no relation between age, sex and type of virus. rotavirus was detected in 50% of astrovirus positive samples. rotavirus was detected with ELISA. astroviruses are an important viral agents of gastroenteritis in Iran. Because of co-infection of astrovirus, improved personal hygiene and rotavirus vaccination will reduce the incidence of co-infections.

**Viral infections and host**

## **DEAMINASE ACTIVITY OF APOBEC3 IS REQUIRED FOR EFFICIENT RESTRICTION OF PORCINE ENDOGENOUS RETROVIRUS**

Y. Jung<sup>1</sup>, H. Kim<sup>1</sup>, D. Kim<sup>1</sup>

<sup>1</sup>Microbiology, Dankook University, Cheonan, Korea

### **Background**

Porcine endogenous retroviruses (PERVs) present a unique concern associated with xenotransplantation because they have been shown to infect certain human cells *in vitro*. Human APOBEC3G (huA3G) is a single-strand DNA cytosine deaminase, which inactivates the coding capacity of the virus by deamination of cDNA cytosines to uracils. This reaction occurs within (-) DNA strand during reverse transcription, resulting in G-to-A mutation in the (+) strand.

### **Objectives**

A recent report showed that huA3G also could inhibit viral replication by cytidine deaminase-independent mechanisms. Two contrasting results with regard to huA3G-dependent inhibition of PERV transmission have been reported. Some group suggests that the mechanism of inhibition does not require the DNA deaminase activity of huA3G. In contrast, other group report that PERV restriction is attributed to cytidine deamination.

### **Methods**

To determine whether DNA deamination is required for huA3G-dependent inhibition of PERV transmission, we established a new set of 293-PERV-PK-CIRCE (human 293 cells infected with PK15-derived PERVs) clones stably expressing huA3G. In addition to huA3G, we included porcine APOBEC3G(poA3Z2-Z3) and murine APOBEC3(mA3). 293T cells were infected with virus-containing supernatant from 293-PERV-PK-CIRCE clones expressing huA3G, poA3Z2-Z3 and mA3. To search for antiviral mechanism of APOBEC3, genomic DNA from 293T cells was prepared at 10h postinfection and the PERV gag gene from 3D-PCR(differential DNA denaturation PCR) product was sequenced.

### **Conclusions**

huA3G, poA3Z2-Z3 and mA3 induced G-to-A hypermutations in the PERV genome effectively. Based on these results, we conclude that the APOBEC3 restricts PERV replication by deaminase-dependent mechanism.

<sup>7</sup>Public Health, Istanbul University Cerrahpasa Medical Faculty, ISTANBUL, Turkey

**Background**

Gynecomastia was indicated as a diseases which develops due to multifactorial causes.

**Objectives**

Based on adipose tissue affinity of Ad-36, we hypothesized, Ad-36 may also play a role in the development of gynecomastia by possibly accompanying increased regional adiposity.

**Methods**

In this cross-sectional and case-control based study, 33 adult male (BMI  $\leq$  25 kg/m<sup>2</sup>) and 15 adult male (BMI  $\leq$  25 kg/m<sup>2</sup>) with anatomic disorders without gynecomastia pathology were included in this study as patient group (PG) and patient control group (PCG), respectively. Breast reduction samples obtained by the lipoaspiration/subcutaneous mastectomy method, were studied by PCR methods.

Simultaneously, the presence of Ad-36 antibodies and serum leptin and adiponectin levels were assessed by serum neutralization assay (SNA) and ELISA, respectively.

## **Conclusions**

Ad-36 antibody was detected in 8 (24.2%) out of 33 PG by SNA and was statistically significant ( $p < 0.05$ ). Mean leptin levels were higher in the Ad-36 positive group, while adiponectin levels were found to be lower in the Ad-36 positive group. We couldn't detect Ad-36 DNA in breast reduction samples; however, we detected significantly higher Ad-36 antibody levels in the PG compared to the PCG. Ad-36 antibody positivity stayed in models in multivariate logistic regression analysis (with backward modeling) and has been identified as a risk factor. We report firstly Ad-36 may be a risk factor in gynecomastia. Moreover, with regard to leptin, adiponectin and serum cholesterol levels, our results suggest that there might be a relationship between Ad-36 and gynecomastia.

<sup>2</sup>Laboratory of Molecular Biology (affiliated with the University of Gdansk) Institute of Biochemistry and Biophysics, Polish Academy of Science, Gdansk, Poland

**Background**

*Klebsiella pneumoniae* is a facultative anaerobic Gram-negative bacterium associated with pyoderma in animals. *K. pneumoniae* can acquire resistance to carbapenems, thus becoming insensitive to almost all available antimicrobial agents. Phage therapy has the potential to replace antibiotic treatment. Lytic bacteriophages and/or their gene products such as lysins, can be easily used as therapeutic agents against bacteria as they are host specific and generally show no side effects.

**Objectives**

We focused on isolation and characterization of new bacteriophages against *Klebsiella pneumoniae*, which can be potentially used in phage therapy in animals.

**Methods**

We collected *K. pneumoniae* swab samples from the infected animals that could not have been treated with a standard antibiotic therapy. Afterwards, new lytic phage PRA33 was isolated from sewage and, with the use of electron microscopy analysis, it was structurally defined as a member of the *Siphoviridae* family. Phage plaque morphology analysis (the plaque clarity and the ability to increase its diameter in time) and determination of phage host range were carried out. Then, analysis of kinetics of adsorption and one-step growth curves were determined in bacteria growing with slow growth rates in a chemostat system. We also performed phage stability tests in various liquid media. Phage genome was sequenced *de novo* and the identification of putative ORFs was undertaken.

**Conclusions**

Based on the results of our experiments, we propose PRA33 phage to be a promising candidate for application in phage therapy against *K. pneumoniae* causing infections in animals that are otherwise difficult to treat.

**FEMS-2306**

**Viral infections and host**

## **DEVELOPMENT AND EVALUATION OF A SEROLOGICAL CHIKUNGUNYA ANTIBODY DETECTION ASSAY**

A. Latz<sup>1</sup>

<sup>1</sup>*R+D, NovaTec Immundiagnostica GmbH, Dietzenbach, Germany*

### **Background**

Chikungunya (also named breakbone fever) is a highly emerging disease in many tropical settings with great socioeconomic impact. Chikungunya-Viruses are transmitted to humans by bloodsucking mosquitoes (*Aedes aegypti*, *Aedes albopictus*). The symptoms of Chikungunya include fever which can reach 39°C (102,2°F) a petechial or maculopapular rash usually involving the limbs and trunk, and arthralgia or arthritis affecting multiple joints which can be debilitating. The fever typically lasts for two days and abruptly comes down. Alphaviruses can be noticed as import or travel associated infection.

### **Objectives**

The aim of this work was to develop an serological assay to detect IgG and IgM antibodies against Chikungunya and to evaluate in endemic outbreak settings.

### **Methods**

An IgG-capture and IgM-capture ELISA was developed. Both take advantage of native antigens produced with a proprietary technique. In house measurements as well as external evaluations in many endemic regions of the world conducted by well know tropical institutes revealed excellent clinical sensitivity and specificity as well as high positive and negative predictive values. Data from the current outbreak in the Caribbean will be discussed.

### **Conclusions**

The newly developed ELISA seems to be a superior tool to diagnose past and acute Chikungunya infection in common and outbreak settings all over the world. It will assist diagnosis of travel returners with unknown fever as well as military in endemic operation area. To further improve Chikungunya diagnostic a Lineblot is currently under development as tool for conformation of ELISA results as well as for small labs with limited lab equipment.

**VACCINE-TYPE ATTENUATING MUTATIONS IN HIGHLY PASSAGED STRAIN OF VARICELLA ZOSTER VIRUS**

J. Jeon<sup>1</sup>, Y. Won<sup>1</sup>, I. Kim<sup>1</sup>, J. Yoon<sup>1</sup>, M. Kim<sup>1</sup>, C. LEE<sup>1</sup>

<sup>1</sup>Microbiology, Chungbuk National University, Cheongju, Korea

Background: Varicella-zoster virus (VZV) is causative agent for chickenpox and zoster. Live attenuated vaccines have been developed based on Japanese Oka strain and Korean MAV/06 strain. Comparison of the complete sequences between vaccine and wild-type strains suggested at least 24 mutations important for attenuation in vaccine strains. Certain strains with high in vitro passage history such as the strains Ellen and 32p72 contained some of the vaccine-type mutations. Objective: In this study, we attempted to understand vaccine-type attenuating mutations in highly passaged VZV strains.

Methods: Genome sequences of clinical strains with different passages were determined by next-generation sequencing and compared with those of other VZV strains.

Conclusion: Vaccine-type mutations were found at position 106262 (T→C) in the Korean clinical strain YC01 passage 32 and at positions 560 (T→C), 105169 (A→G), 106262 (T→C) and 107252 (T→C) in YC01 passage 61. Similar mutations were also found in high-passaged another clinical strain YC02 at positions 560, 106262 and 107252. Same mutations at 106262 and 107252 were found in the strains Ellen and 32p72. Thus, in the course of in vitro passaging of VZV, mutations at 106262 and 107252 seemed to occur first, and followed by mutation at 560. Direct PCR sequencing of these positions in YC01 and YC02 strains at various passages identified the passage numbers when the attenuating mutations occurred. Further studies of in vitro passaging under attenuating conditions such as low temperature or guinea pig cells will help to understand the mechanism of attenuating mutations in VZV.

**LIPIDATED DENGUE-2 ENVELOPE PROTEIN DOMAIN III INDEPENDENTLY STIMULATES LONG-LASTING NEUTRALIZING ANTIBODIES AND REDUCES THE RISK OF ANTIBODY-DEPENDENT ENHANCEMENT**

C. Chiang<sup>1</sup>, C. Pan<sup>1</sup>, C. Hsieh<sup>1</sup>, J. Tsai<sup>1</sup>, M.Y. Chen<sup>1</sup>, H.H. Liu<sup>1</sup>, S.J. Liu<sup>1</sup>, P. Chong<sup>1</sup>, C. Leng<sup>1</sup>, H.W. Chen<sup>1</sup>

<sup>1</sup>National Institute of Infectious Disease and Vaccinology,  
National Health Research Institutes, Miaoli, Taiwan

**Background**

Dengue virus is a mosquito-transmitted virus that can cause self-limiting dengue fever, severe life-threatening dengue hemorrhagic fever and dengue shock syndrome. The existence of four serotypes of dengue virus has complicated the development of an effective and safe dengue vaccine. Recently, a clinical phase 2b trial of Sanofi Pasteur's CYD tetravalent dengue vaccine revealed that the vaccine did not confer full protection against dengue-2 virus. New approaches to dengue vaccine development are urgently needed. Our approach represents a promising method of dengue vaccine development and may even complement the deficiencies of the CYD tetravalent dengue vaccine.

**Objectives**

To develop a vaccine with long-lasting neutralizing antibodies and reduces the risk of antibody-dependent enhancement

**Methods**

Two important components of a vaccine, the immunogen and immunopotentiator, were combined into a single construct to generate a new generation of vaccines. We selected dengue-2 envelope protein domain III (D2ED III) as the immunogen and expressed this protein in lipidated form in *Escherichia coli*, yielding an immunogen with intrinsic immunopotential activity.

**Conclusions**

The formulation containing lipidated D2ED III (LD2ED III) in the absence of exogenous adjuvant elicited higher D2ED III-specific antibody responses than those obtained from its nonlipidated counterpart, D2ED III, and dengue-2 virus. In addition, the avidity and neutralizing capacity of the antibodies induced by LD2ED III were higher than those elicited by D2ED III and dengue-2 virus. Importantly, we showed that after lipidation, the subunit candidate LD2ED III exhibited increased immunogenicity while reducing the potential risk of antibody-dependent enhancement of infection in mice.

**NANOPARTICLES-BASED VACCINE INDUCES PROTECTIVE IMMUNITY AGAINST EV71 INFECTION IN TOLL-LIKE RECEPTOR 9 KNOCKOUT MOUSE ANIMAL MODEL**

S. Liu<sup>1</sup>, H. Hsiao<sup>1</sup>, A. Chou<sup>1</sup>, S.U.I. Lin<sup>1</sup>, I.H.U.A. Chen<sup>1</sup>, S. Lien<sup>1</sup>, C. Liu<sup>1</sup>, P.E.L.E. Chong<sup>1</sup>

<sup>1</sup>*National Institute of Infectious Diseases and Vaccinology, National Health Research Institutes, Miaoli, Taiwan*

**Background:**

Enterovirus 71 (EV71), a positive-stranded RNA virus, is the major cause of hand, foot and mouth disease (HFMD) with severe neurological symptoms. Seven-day-old toll-like receptor 9 knockout (TLR9KO) mice infected with a non-mouse adapted EV71 strain developed neurological lesion-related symptoms, including hindlimb paralysis, slowness, ataxia and lethargy. Histopathological examination revealed a massive damage in the limb muscles, brain, and spinal cord. The TLR9KO mouse could be useful as EV71 animal model to study anti-EV71 drugs and vaccines.

**Objectives:**

A novel nanoparticle-based EV71 VP1 peptide vaccine was evaluated in the EV71 mouse model. The clinical symptoms of mice after EV71 infection were monitored

**Methods:**

Seven-day-old TLR9KO mice were infected with non-mouse adaptive EV71 and showed neurological diseases. We found that EV71 alone cannot activate toll-like receptor 9 (TLR9) signaling. On the contrast, supernatant from EV71-infected cells could activate TLR9. Furthermore, we identified the EV71-infected cells-derived danger signal activate TLR9 to protect mice from EV71 challenge. To investigate whether TLR9KO mice could be used as an animal model for EV71 vaccine development, EV71-infected TLR9KO mice were treated with sera from vaccinated mice. We designed a VP1 peptide of EV71 that formulated with emulsion type nanoparticles adjuvant and immunization with wild type mice. Sera from immunized mice were administered to EV71-infected TLR9KO mice, and clinical neurological symptoms of mice were observed.

**Conclusions:**

Sera from EV71 VP1 peptide immunized mice could reduce neurological symptoms of TLR9KO mice from challenged with EV71.

**ALGAL VIRUS PRODUCTION IS NEGATIVELY AFFECTED BY PHOSPHORUS AND NITROGEN LIMITATION, BUT THIS MAY BE COUNTERACTED BY NUTRIENT ASSIMILATION DURING INFECTION**

D.S. Maaß<sup>1</sup>, C.P.D. Brussaard<sup>1</sup>

<sup>1</sup>*Biological Oceanography, Netherlands Institute for Sea Research (NIOZ), 't Horntje, Netherlands*

**Background**

Viruses are a main cause of phytoplankton mortality, thereby controlling their community composition and driving biogeochemical cycling in the marine environment. Phytoplankton growth and production is often limited by nitrogen (N) and/ or phosphorus (P), which can affect the virus growth characteristics upon infection. The influence of nutrient limitation on phytoplankton – virus interactions are, however, still poorly studied. As climate change will lead to an expansion of stratified and consequently nutrient limited oceanic regions, it is important to understand how phytoplankton mortality rates in the future marine environment will be affected by these changes.

**Objectives**

Our goal was to study the effects of N- and P-limitation on virus host interaction and the potential relieve of these effects by the uptake of nutrients during viral infection.

**Methods**

Therefore, cultures of the the phytoplankton species *Micromonas pusilla* and *Phaeocystis globosa* were grown semicontinuously under limitation of either P, N, or NP until the moment of infection. Upon infection the abundances of host cells and viruses were monitored to obtain one-step growth curves.

**Conclusions**

Nutrient limitation led to elongated viral latent periods (up to 3-fold) and strongly reduced (up to 8-fold) burst sizes, whereby the outcome was dependent on both the species and the limiting nutrient involved. Furthermore, the negative effects of P-limitation on virus production in the picophytoplankter *M. pusilla* could be overcome by spiking the infected and P-limited cultures with small pulses of inorganic and organic P, simulating bacterial remineralization and supply by lysis of neighboring cells, respectively.

<sup>2</sup>*Pediatric Hematology Unit, Nakornping Hospital, Chiang Mai, Thailand*

<sup>3</sup>*Department of Pediatrics, Chiang Mai University, Chiang Mai, Thailand*

**Background**

In recent years, several new viruses associated with diarrheal diseases in human have been reported. Saffold virus (SAFV) is one of a newly identified human Cardiovirus reported for the first time in 2007.

**Objectives**

This study investigated the prevalence of SAFV and characterized the genotypes distributed in children with diarrhea in Chiang Mai, Thailand during 2012-2013.

**Methods**

A total of 608 fecal specimens collected during January 2012 to December 2013 from children with diarrhea in Chiang Mai, Thailand were investigated for SAFV by RT-nested PCR and performed sequence analysis.

**Conclusions**

Nine out of 608 (1.5%) were positive for 4 genotypes of SAFV, SAFV1, SAFV2, SAFV3, and SAFV4. SAFV mono-infection was found in 5 cases, while co-infection with other viruses that cause diarrhea was observed in 4 cases. This study provides more information about SAFV genotypes circulating in pediatric patients with diarrhea in Thailand.

**THE CYTOKINES EXPRESSION IS MODULATED BY EPIGENETIC MECHANISMS  
IN RESPONSE TO INFECTION WITH IPNV**

R. Manríquez<sup>1</sup>, T. Vera<sup>1</sup>, R. Avendaño<sup>2</sup>, J.G. Carcamo<sup>1</sup>

<sup>1</sup>*Instituto de Bioquímica y Microbiología, Universidad Austral de Chile, Valdivia, Chile*

<sup>2</sup>*Genómica Marina y Recursos Nativos,  
Interdisciplinary Center for Aquaculture Research (INCAR)., Viña del Mar, Chile*

**Background**

The massive salmon farming associated to aquaculture industry has brought a significant increase in infectious diseases, thereby generating economic losses. The infectious pancreatic necrosis virus (IPNV), agent of high mortalities in fish farmed, has capacity to activate the immune response mediated by interferon in their host; the aim of this study is clarify whether the activation of the antiviral response caused by IPNV is through epigenetic mechanisms.

**Objectives**

We observed that expression of cytokines, in salmonids cells infected with IPNV was associated to promoter methylation status. Moreover, DNA methyltransferase inhibitors treatments were able to modulate the expression of these cytokines.

**Methods**

Studies of methylation in CpG islands of the promoters of cytokines in infected salmonids cells with IPNV were conducted. Through bisulfite sequencing, change in methylation of the promoter affecting the expression of interferon was evaluated. Furthermore, treatments with DNA methyltransferase (DNMT) inhibitor 5-azacytidine and 5-Aza-2'-deoxycytidine were performed to evaluate the expression of cytokines.

**Conclusions**

These results show that cytokines expression is regulated by promoter methylation status which could be correlated with the modulation of DNMT activity when cells are infected with IPNV. Our work suggested that epigenetic mechanisms could participate in the regulation of host genes expression in IPNV infection, and provided a new insight into understanding the mechanisms of viral infection.

**EPIDEMIOLOGICAL, CLINICAL MANIFESTATION AND GENOTYPE CHARACTERIZATION OF HEPATITIS-C VIRUS AMONG THE HIV PATIENTS IN KASHAN**

*H. Afzali<sup>1</sup>, M. Momen-Heravi<sup>1</sup>, A. Farrokhzad<sup>1</sup>*

*<sup>1</sup>infectious disease, Kashan University of Medical Sciences, Kashan, Iran*

**Background**

Due to shared transmission routes, HCV infection is highly prevalent among people infected with human immunodeficiency virus (HIV). Little is known about the characteristics of HCV genotypes in among HIV/HCV coinfecting patients in Kashan

**Objectives**

In order to provide valuable information for HCV management in this particular population, we investigated the HCV genotypes in HIV-infected In Kashan-Iran.

**Methods**

This study was conducted in 2013 in kashan, Iran. The study population consisted of all HIV infected having records in behavioural counselling center and prison in Kashan . Demographic information and HCV, HIV-related risk behaviours were obtained through an interviewer-assisted questionnaire. After taking consent form, 10 cc blood taken from HIV patients and serum samples were screened for HCV infection using enzyme-linked immunosorbent assay (ELISA), and detection of HCV RNA was performed by PCR amplification. HCV subtypes were determined by direct sequencing of amplicons

**Conclusions**

54(85%) out of the 63 HIV infected patients , were HCV positive which all of them were male..there was a significant correlation between HCV frequency and occupation ( $P<0.0001$ ) and level of education ( $p<0/05$ ). 100% of HIV/HCV coinfecting cases had history of illicit drug use,92.6% history of prison and and 40.7% had high risk sexual behavior. There was found genotype 1 in 75.9% and genotype 3 in 24.1% of HCV patients .94.4% of HCV patients had subtype a. The mean of AST,ALT,TLC,CD4 in HCV patients were 50.6,58.5,397.2,398.8. There was no clinical symptom of chronic Hepatitis c.

The majority of HIV infected persons in Kashan city are HCV positive and predominant genotype is 1 and predominant subtype is a.

## **PREVALENCE OF HEPATITIS C IN INJECTING DRUG USERS IN KASHAN -IRAN**

M. Momen-Heravi<sup>1</sup>, H. Afzali<sup>1</sup>, R. Razzaghi<sup>1</sup>

<sup>1</sup>*infectious disease, Kashan University of Medical Sciences, Kashan, Iran*

### **Background**

Drug injection is a very important risk factor for viral hepatitis and human immunodeficiency virus (HIV) infection

### **Objectives**

The present study was performed to evaluate the prevalence of hepatitis C among injection drug users (IDUs) and to identify the related risk factors for these infections in this group.

### **Methods**

This descriptive-analytical study was conducted in 2011 in kashan, Iran. The study population consisted of 300 IDUs in MMT, DIC and counselling centers. Demographic information and HCV related risk behaviors were obtained through an interviewer-assisted questionnaire. IDUs serum samples were screened HCV infection using enzyme-linked immunosorbent assay (ELISA). Data analyzed using Spss.

### **Conclusions**

Of the 300 IDUs, 288 (96%) were male. The majority of IDUs 127 (42.3%) were in 30-39 age group with mean age  $34.9 \pm 9.7$ . The majority of IDUs 224 (74.7%) had more than 10 years history of addiction. The most common age of onset addiction was 15-20 year 134 (44.7%). The prevalence of HCV was 142 (47.3%). It was found that there was a significant correlation between using shared syringe, age and times of prison and HCV infection.

There was high prevalence of HCV among IDU. High risk behaviors such as tattooing, unsafe sex, needle sharing are common so regular screening of IDU, education of personal Health about using sterile syringe, HBV vaccination and treatment of addiction and HCV infection is recommended.

**DETECTION AND PHYLOGENETIC ANALYSIS OF TORQUE TENO VIRUS (TTV) AMONG BLOOD DONORS AND HBC OR HBV-INFECTED PATIENTS IN QATAR**

G. Nasrallah<sup>1</sup>, R. AbuOdeh<sup>2</sup>, N. Al-Mawlawi<sup>3</sup>, A. Al-Qahtani<sup>4</sup>, A. Khan<sup>1</sup>, M. Smatti<sup>1</sup>, N. Ali<sup>1</sup>

<sup>1</sup>Health Sciences, Qatar University, Doha, Qatar

<sup>2</sup>Health Sciences, King Saud bin Abdulaziz University For Health Sciences, Jeddah, Saudi Arabia

<sup>3</sup>Department of Laboratory Medicine and Pathology, HMC, Doha, Qatar

<sup>4</sup>Department of Infection and Immunity, King Faisal Specialist Hospital, Riyadh, Saudi Arabia

**Background**

TTV has been linked to non A-G hepatitis

**Objectives**

The aim of this project was to investigate the rate of infection and to determine the genotypic features of TTV in Qatar

**Methods**

A total of 644 blood samples representing different nationalities, non-Qatari (526) and Qatari (118) nationals (mostly from Arab and South East Asia countries) were studied for the presence of TTV DNA by nested PCR. The majority (573) of the blood samples belonged to healthy blood donors, while 53 and 54 of the blood samples belonged to hepatitis C virus (HCV) and hepatitis B virus (HCV)-infected patients, respectively.

**Conclusions**

**Results:** we showed that the infection rates of TTV in blood donors, and those HCV or HBV-infected patients were 81.4%, 84.9% and 90.75%, respectively. Significant association found between TTV viremia and nationality, or age was detected. Sequence analysis of PCR fragments amplified from the 5'-untranslated region (5'-UTR) of all (531) TTV positive samples showed that 65.5% (348/531) of the PCR fragment sequences were classified into main genotype 3, followed by genotype 5 (24%), 2 (5.8%) and 1 (4.7%). Interestingly, genotype 4 was not detected among the studied subjects. Phylogenetic and pairwise analyses using sequences from TTV viremic samples also showed an overall close similarity to the main genotype 3. **In conclusion**, there was no significant difference in the detection rates of TTV among Qatari nationals and non-nationals, and most TTV genotypes, particularly genotype 3, were detected

**Viral infections and host**

**PARTIAL CHARACTERIZATION OF A PROBABLE NOVEL SUBTYPE OF  
BETAPAPILLOMAVIRUS HPV 17**

L. OLIVEIRA<sup>1</sup>, L. SANTOS<sup>1</sup>, F. NEVES<sup>1</sup>

<sup>1</sup>*Microbiology and Parasitology, Federal Fluminense University, Niterói, Brazil*

**Background**

Human papillomavirus (HPV) have epithelial and mucosal tropism. HPV type 17 belongs to cluster *b2* of *Betapillomavirus*. Distinct subtypes with dissimilarities of 2 to 10% at the nucleotide level from their reference HPV can be identified. Molecular cloning experiments enabled to recognize two subtypes (17a and 17b) isolated from epidermodysplasia verruciformis (EV)

**Objectives**

The aim of this study was investigate a possible novel subtype of *Betapapillomavirus* HPV type 17.

**Methods**

The isolate was collected from an oral mucosa of an asymptomatic woman. Partial L1 region was amplified using My09/11 degenerated primers. The complete E6, E7, and LCR genes were amplified with specific primers. The Ethics Committee of the College of Medicine at the University approved the protocols for collection and informed consent.

**Conclusions**

The viral DNA was sequenced and partially characterized. Within these sets, the DNA sequence was altered at 38 positions (15 in L1, 13 in E6, 8 in E7, and 2 in LCR gene). Partial L1 analysis showed high dissimilarity facing to prototype, reaching 5% of nucleotide substitutions. The E6 oncoprotein presented the highest modification among the sequences studied. The amino acid modified at position 62 (S-T) affected one zinc binding domain (CxxC(C)<sub>29</sub>CxxC) of this protein. E2 binding factors, transcription factors, and TATA signals were seen in LCR region. Despite the EV-associated HPV 17 has cutaneous tropism, the oral cavity is an appropriated niche to host HPV which naturally infects other sites. Based on these findings, we believe to have found a novel subtype of this type.

<sup>8</sup>Graduate school of agricultural sciences, Tohoku university, sendai Aoba-ku, Japan

### **Background**

Rotavirus (RV) is a primary cause of acute diarrhea in infants and young animals, and despite attenuated RV vaccines have been able to reduce the global disease burden associated with RV gastroenteritis, this infectious disease is still a problem in developing countries. Several reports indicate that immunobiotics have the ability to reduce severity of RV mediated diarrhea. Previously, we demonstrated that some immunobiotic strains were able to beneficially modulate Toll-like receptor (TLR)-3 mediated immune response in porcine intestinal epithelial (PIE) cells.

### **Objectives**

To evaluate the capacity of immunobiotics to modulate RV-induced antiviral response in PIE cells.

### **Methods**

(i) PIE and MA104 cells were inoculated with several strains of RVs to investigate the susceptibility and the ability to induce the inflammatory cytokines against RV infection, (ii) The capacity of immunobiotics to beneficially modulate RV-induced immune response in PIE cells was investigated, by evaluating inflammatory cytokines, type I interferons, TLR signaling pathways, and TLR negative regulators.

### **Conclusions**

Challenge of PIE cells with RV reduced cell viability and increased the expression of IFN- $\beta$ , MCP-1, IL-6, IL-8, and TLR3. Immunobiotics were able to improve cell viability, and to reduce RV-induced inflammatory cytokines expression. Those effects were related to the capacity to modulate TLR negative regulators single such as SIGIRR, Tollip, A20, Bcl-3, IRAK-M, and MKP-1. Our results demonstrated that immunobiotics can be used as immunomodulators to alleviate viral induced diarrhea in livestock animals such as the pig.

**NON-VIABLE IMMUNOBIOTIC LACTOBACILLUS RHAMNOSUS CRL1505 IMPROVES RESPIRATORY IMMUNITY AND REDUCES INFLUENZA VIRUS-ASSOCIATED LUNG INJURY**

K. Paulraj<sup>1</sup>, H. Zelaya<sup>2</sup>, M. Vizoso-Pinto<sup>3</sup>, S. Salva<sup>2</sup>, S. Alvarez<sup>2</sup>, H. Kitazawa<sup>1</sup>, V. Julio<sup>2</sup>

<sup>1</sup>Graduate school of agricultural sciences, Tohoku university, Sendai Aoba-ku, Japan

<sup>2</sup>Laboratory of Immunobiotechnology, Reference Centre for Lactobacilli (CERELA-CONICET), Tucuman, Argentina

<sup>3</sup>Laboratory of Immunobiotechnology, Reference Centre for Lactobacilli (INSIBIO-CONICET), Tucuman, Argentina

**Background**

Symptoms of influenza infection are variable ranging from mild respiratory distress to massive organ failure resulting in death. Seasonal influenza is usually self-limiting but in susceptible patients it may progress to acute lung injury, which is characterized by augmented pulmonary microvascular permeability, hypoxemia and respiratory failure. The ongoing threat of influenza epidemics and pandemics has emphasized the importance of developing novel, safe and effective therapeutic or preventive strategies against infections from divergent influenza viruses.

**Objectives**

To examine the effect of nasal administration of heat-killed *Lactobacillus rhamnosus* 1505 (Lr1505) on immune response to influenza infection in mice.

**Methods**

Six-week old BALB/c mice were treated with  $10^8$  cells of Lr1505 by the nasal route during two consecutive days. Lr1505-treated and untreated control mice were then nasally challenged with Influenza virus. Lung tissue damage and respiratory and systemic immune responses were studied at several time points after viral challenge. Results demonstrated that non-viable immunobiotic strain protected infected mice by reducing pulmonary injury and lung viral loads through several mechanisms: a) inflammatory cytokines were down-regulated diminishing inflammation ( $p < 0.01$ ), b) IFNs with direct antiviral activity were enhanced ( $p < 0.01$ ), c) regulatory cytokines IL-10 was up-regulated ( $p < 0.05$ ), d) maturation markers and co-stimulatory molecules were up-regulated in lung antigen presenting cells ( $p < 0.01$ ), e) IFN- $\gamma$  and IL-10 producing CD4<sup>+</sup> lymphocytes were recruited to the lungs.

**Conclusions**

Our results strongly suggest that administration of Lr1505 may represent an interesting alternative to modulate respiratory immune response and reduce influenza

virus-associated pulmonary damage.

Viral infections and host

# POPULATION DYNAMICS OF A CYANOBACTERIUM MICROCYSTIS AERUGINOSA USING AMPLICON ANALYSIS FOR THE LEADER-END CRISPR FRAGMENTS

Y. Takashi<sup>1</sup>, M. Uehara<sup>1</sup>, G. Nakamura<sup>1</sup>, M. Nakata<sup>1</sup>, Y. Sako<sup>1</sup>

<sup>1</sup>Graduate school of agriculture, Kyoto University, Kyoto, Japan

**Background.** Freshwater cyanobacterium *Microcystis aeruginosa* frequently forms massive natural blooms where the cell densities are comparable to those in laboratory media ( $10^7$  to  $10^8$  cells/ml). The representative genome of this species contains abundant and diverse potential anti-viral defense genes. Our culture analyses showed distinct CRISPR arrays in this species. This suggested the *Microcystis* cyanophage may have co-evolved with its phage in a frequency-dependent selection.

**Objectives.** The aim of this study is to understand the co-evolutionary dynamics of the *Microcystis* cyanophage in natural settings.

**Methods.** The CRISPR diversity of *Microcystis aeruginosa* was examined in a small eutrophic pond using amplicon analysis of the leader-end of CRISPR fragments with a MiSeq mini-gene sequencer.

**Conclusions.** During the sampling period, a CRISPR-related genotype (CT19) occurred frequently in the *Microcystis* population. A qPCR targeting CT19 showed the copy numbers were from  $4.9 \times 10^2$  and  $3.2 \times 10^5$  copies  $\text{mL}^{-1}$  and accounted for 0.2 % to 18 % of the *Microcystis* population. We obtained 176,800 leader-end CRISPR fragments using amplicon sequencing. Of these, 116,466 were reclassified into CT19 consisting of two major variants (28% and 72%, respectively). These major CTs co-existed and their numbers oscillated throughout the sampling periods. A few new variants were found to acquire new spacers or the lack of spacers at the leader-end of the major variants. This indicates *Microcystis* cyanophage co-evolution creates a few new genetic variations and also maintains the genetic diversity in the population.

**PRODUCTION IN YEAST OF HUMAN BOCAVIRUS 1-4 VP2 VIRUS-LIKE PARTICLES AND GENERATION OF VP2-SPECIFIC MONOCLONAL ANTIBODIES AS NOVEL TOOLS FOR BOCAVIRUS SEROLOGY**

*R. Petraityte-Burneikiene<sup>1</sup>, P.L. Tamosiunas<sup>1</sup>, R. Lasickiene<sup>2</sup>, R. Firantiene<sup>3</sup>, R. Emuzyte<sup>3</sup>, A. Zvirbliene<sup>2</sup>, K. Sasnauskas<sup>1</sup>*

<sup>1</sup>*Department of Eukaryote Gene Engineering, Vilnius University Institute of Biotechnology, Vilnius, Lithuania*

<sup>2</sup>*Department of Immunology and Cell Biology, Vilnius University Institute of Biotechnology, Vilnius, Lithuania*

<sup>3</sup>*Clinic of Children's Diseases Faculty of Medicine, Vilnius University, Vilnius, Lithuania*

**Background**

Human bocavirus 1 (HBoV1), first described in 2005, was considered a causative agent of previously unexplained respiratory tract diseases. Recently, 3 new members of genus *Bocavirus*, HBoV2-4 were described. HBoV2-4 occurs mainly in the gastrointestinal tract but rarely in the respiratory tract, contrary to HBoV1.

**Objectives**

Recombinant viral antigens have been proven useful for serologic diagnosis of viral infections. Production of HBoV1-4 antigens in yeast expression system has not yet been reported. In the current study, the capsid proteins VP2 of HBoV1 - 4 were expressed in yeast *S.cerevisiae*. Electron microscopy demonstrated that all purified recombinant proteins self assembled into virus-like particles (VLPs) exhibiting the typical icosahedral appearance of parvoviruses with a diameter of approximately 20 nm. HBoV1 - 4 VP2 VLPs were stable in yeast and were easily purified by caesium chloride gradient ultracentrifugation. Four monoclonal antibodies (MAbs) of IgG1 subtype were generated by immunization of mouse with recombinant HBoV1 VP2 VLPs. Three of them specifically recognized only HBoV1 VP2 protein; one MAb was cross-reactive with HBoV2 and HBoV4 VP2 proteins. Recombinant HBoV1-4 VP2 VLPs and VP2-specific MAbs were employed to develop serological assays to detect virus-specific IgG antibodies in human serum specimens.

**Methods**

Cloning of HBoV VP2 proteins coding sequences into yeast vectors and purification of virus-like particles from yeast. Electron microscopy. SDS-PAGE and Western blotting analysis. Indirect ELISA. IgG capture ELISA. Generation of monoclonal antibodies.

**Conclusions**

Yeast expression system proved to be simple, efficient and cost-effective, suitable for high-level production of HBoV1- 4 VP2 as VLPs, that resemble native virus in regards of morphology and antigenicity.

**Viral infections and host**

## **REMARKABLE DIVERSITY AMONG NOVEL DENSOVIRUSES FROM CRICKETS**

P. Tijssen<sup>1</sup>, H.T. Pham<sup>1</sup>, Q. Yu<sup>1</sup>

<sup>1</sup>*Virology, INRS–Institut Armand-Frappier, Laval, Canada*

### **Background**

Densoviruses are members of the Parvoviridae family infecting invertebrates. Since 2009, a cricket densovirus, AdDV, caused a severe epidemic in the \$ 600-million cricket industry in North-America.

### **Objectives**

During the last 18 months, we also received samples of diseased crickets from North America, Europe and Japan that were negative for AdDV. Electron microscopy demonstrated that these samples contained densovirus-like particles. Objectives of this study included characterization of these virus(es), cloning, sequencing, and X-ray crystallography.

### **Methods**

A SISPA method was used to detect the pathogens (J Virol 88:12152). Sequencing of the amplicons identified those with identities to known viruses allowing by primer extension to obtain the complete genomes and cloning in suitable vectors to obtain infectious clones. Sequencing revealed that some were novel circoviruses and a novel ambisense densovirus (Genome Announc. 1(2):e00079-13, 1(3):e00328 and 131(6):e00914-13). However, the greatest surprise was a densovirus with a segmented genome (AdSDV). NS- and VP- coding sequences are in separate segments of about 3.3 kb. Both NS- and VP- segments are flanked by identical hairpin terminal sequences but lack ITRs. The two ORFs for VP arose through recombination between a mosquito brevidensovirus and AdDV. The downstream ORF with AdDV-VP1up-like phospholipase A2 could be spliced to the C-terminus of the major capsid protein. Currently, the capsid structure (X-ray crystallography) and transcription strategy of AdSDNV.

### **Conclusions**

A brevidensovirus that normally infects only mosquitoes has adapted itself through recombination with AdDV to crickets. These findings necessitate a revision of the definition and taxonomy of parvoviruses.

**Viral infections and host**

**TIME SINCE ONSET OF DISEASE AND INDIVIDUAL CLINICAL MARKERS  
ASSOCIATE WITH TRANSCRIPTIONAL CHANGES IN UNCOMPLICATED  
DENGUE**

H. van den Ham<sup>1</sup>

<sup>1</sup>*Viroscience, Erasmus MC University Medical Center, Rotterdam, Netherlands*

**Background**

Dengue virus (DENV) infection causes viral haemorrhagic fever that is characterized by extensive activation of the immune system.

**Objectives**

The aim of this study is to investigate the kinetics of the transcriptome signature changes during the course of disease and the association of genes in these signatures with clinical parameters.

**Methods**

Sequential whole blood samples from DENV infected patients in Jakarta were profiled using affymetrix microarrays, which were analysed using principal component analysis, limma, gene set analysis, and weighted gene co-expression network analysis.

**Conclusions**

Time since onset of disease associates with the shift in transcriptome signatures from immunity and inflammation to cell cycle and repair mechanisms in patients with non-severe dengue. The strong association of time with blood transcriptome changes hampers both the discovery as well as the potential application of biomarkers in dengue. Clinical diagnosis (according to the WHO classification) does not associate with differential gene expression. However, network analysis did show that that key clinical markers, including platelet count, fibrinogen, albumin, IV fluid distributed per day and liver enzymes SGOT and SGPT, strongly correlate with gene modules that are enriched for genes involved in the immune response. The expression level of these gene modules may support earlier detection of disease progression as well as clinical management of dengue.

## **COMPLEXITY OF THE VIROME FROM THE KY ISOLATE OF PHOMOPSIS LONGICOLLA FUNGUS**

I. Koloniuk<sup>1</sup>, L. Hrabáková<sup>2</sup>, K. Petrzik<sup>1</sup>

<sup>1</sup>Plant Virology Department,

Institute of Plant Molecular Biology Biology Centre of the CAS, Ceske Budejovice, Czech Republic

<sup>2</sup>Department of Genetics,

Faculty of Science University of South Bohemia in České Budějovice, Ceske Budejovice, Czech Republic

### **Background**

*Phomopsis longicolla* (teleomorph = *Diaporthe*) is an ascomycete phytopathogenic fungus. Mycoviruses were reported to debilitate their hosts [1]. The KY isolate and derived subcultures of *P. longicolla* exhibited abnormal growth and reduced virulence. Initial examination revealed that the isolate harbors *Phomopsis longicolla* hypovirus 1 (PIHV1) [2]. This ssRNA virus belongs to a group of betahypoviruses that, unlike alphahypoviruses, were not reported to reduce virulence of their hosts.

### **Objectives**

The objective of the study was to investigate potential viral (or other) determinants of hypovirulence and characterise structure and diversity of PIHV1 population in the KY isolate of *P. longicolla*.

### **Methods**

Illumina-based DNA and RNA deep sequencing was performed of a number of the KY subcultures and the type strain of *Phomopsis longicolla* Hobbs, anamorph (ATCC® 60325™).

### **Conclusions**

The analyses of the NGS data revealed that the virome of the KY isolate consists of PIHV1 recombinant with a previously undescribed hypovirus, population of deletion mutants of PIHV1, and a novel RNA virus related to members of *Narnaviridae* family.

## **CHARACTERIZING THE VIROME OF THE ENTOMOPATHOGENIC FUNGUS BEAUVERIA BASSIANA**

I. Kotta-Loizou<sup>1</sup>, M.A. Typas<sup>2</sup>, R.H.A. Coutts<sup>1</sup>

<sup>1</sup>*Division of Cell & Molecular Biology, Imperial College London, London,  
United Kingdom*

<sup>2</sup>*Department of Genetics & Biotechnology, University of Athens, Athens, Greece*

### **Background**

Entomopathogenic fungi are of scientific interest because they enable analysis of virus-host interactions and can be used as biocontrol agents of insect pests. The deuteromycetous fungus *Beauveria bassiana* has a widespread geographical distribution and a wide host range. Mycoviruses have been described mostly in phytopathogenic fungi and are occasionally associated with hypovirulence, while in entomopathogenic fungi presence of mycoviruses has been reported only rarely.

### **Objectives**

The aim of the present study is to detect and analyse the viruses present in a collection of *B. bassiana* isolates sourced from worldwide locations.

### **Methods**

Population studies, RT-PCR, cloning and sequencing, hybridization experiments, time-course studies and transmission electron microscopy (TEM) were used to characterize the virome of *B. bassiana*.

### **Conclusions**

A population study revealed that 17/75 (22.7%) *B. bassiana* isolates harbor dsRNA elements. Two members of the *Partitiviridae* family, *B. bassiana* partitivirus-1 and -2 (BbPV-1 and BbPV-2), have been sequenced, while TEM revealed the presence of virus-like particles. Hybridization experiments revealed that BbPV-1 and BbPV-2 are present in seven *B. bassiana* isolates derived from different hosts and geographical origins. Additionally, four members of the *Totiviridae* family, originating from the Iberian Peninsula and the Canary Islands, have been partially sequenced. Furthermore, two previously uncharacterized viruses, *B. bassiana* polymycovirus-1 (BbPmV-1) and *B. bassiana* non-segmented virus-1 (BbNV-1), have been detected and fully sequenced and the prevalence of further PmV-like viruses in *B. bassiana* is currently under investigation. Finally, a time-course study revealed a strong negative

correlation between the copy numbers of viral dsRNA and the developmental stages of the fungus.

**THE NEW MESOPHILIC FILAMENTOUS ANOXYGENIC PHOTOTROPHIC BACTERIUM FROM SULFIDE HOT SPRINGS.**

V. Gaisin<sup>1</sup>, A. Kalashnikov<sup>2</sup>, E. Burganskaya<sup>1</sup>, B. Kuznetsov<sup>1</sup>, V. Gorlenko<sup>2</sup>

<sup>1</sup>Laboratory of molecular diagnostic, Centre Bioengineering RAS, Moscow, Russia

<sup>2</sup>Laboratory of ecology and geochemical activity of microorganisms,  
Winogradsky Institute of Microbiology RAS, Moscow, Russia

**Background**

Filamentous anoxygenic phototrophic bacteria (FAPB) belong to the deep-branching phylum Chloroflexi, and are considered to be the most ancient lineage of phototrophs. The unambiguous reconstruction of the evolution of FAPB is complicated by poor representativeness of mesophilic FAPB.

**Objectives**

The above mentioned pointed our efforts to the search and study of new mesophilic FAPB in mesothermal cyanobacterial mats from hot springs in Barguzin valley (Buryat Republic, Russia).

**Methods**

Mat samples were collected from mesothermal zones of Umkhey (36 – 40°C) and Kuchiger (35 - 39°C) sulfide hot springs. The enrichment culture containing mesophilic green filamentous anaerobic bacterium Um-2 was obtained from Umkhey mat sample at the Pfenning medium (pH 7.0) at 28°C under illumination. The Um-2 cells (diameter about 0,8 µm) were combined to trichome. The main cellular pigments was bacteriochlorophyll *c* (maximum absorption at 740 nm). Gas vacuoles were not found. According to the phylogenetic test results (by 16S), Um-2 formed the branch belonging to mesophilic FAPB cluster. The nearest neighbor of Um-2 was “*Candidatus Chloroploca asiatica*” Um-3 (KJ605349) (91% of similarity). The Um-2 phylotype representatives was detected in Umkhey and Kuchiger mat samples using PCR test with FAPB-specific *puLM* primers. The sequences of *rrna* (16S rRNA coding) and *puLM* genes were deposited in GenBank under accessions KP341999 and KP342000 respectively.

**Conclusions**

Thus the enrichment culture of new mesophilic FAPB belonging to the new genus and species of the Chloroflexales order was obtained. It was shown that the new bacterium is presented in the microbial community of sulfide springs of Barguzin valley.

#### **ANTIFUNGAL ACTIVITY OF NONHYDROLYTIC SYNTHESIZED TiO<sub>2</sub>**

M. Georgieva-Sredkova<sup>1</sup>, H. Hitkova<sup>1</sup>, V. Popova<sup>1</sup>, A. Stoyanova<sup>2</sup>, N. Ivanova<sup>3</sup>,  
A. Bachvarova-Nedelcheva<sup>3</sup>, R. Iordanova<sup>3</sup>

<sup>1</sup>Department of Microbiology, Medical University-Pleven, Pleven, Bulgaria

<sup>2</sup>Department of Chemistry, Medical University-Pleven, Pleven, Bulgaria

<sup>3</sup>Institute of General and Inorganic Chemistry, Bulgarian Academy of Sciences, Sofia, Bulgaria

#### **Background**

Despite of many studies on antibacterial activity of titanium dioxide (TiO<sub>2</sub>), its antifungal properties are not yet well evaluated.

#### **Objectives**

The aim of our study is to exam the activity of nanosized TiO<sub>2</sub> against yeast cells.

#### **Methods**

TiO<sub>2</sub> used was synthesized by sol-gel method and characterized as anatase with particles size about 20 nm. Its antifungal activity was examined against *C.albicans*, *C.tropicalis*, *C.lusitaniae*, *C.glabrata* and *C.krusei*, using the following experimental setup: concentration of TiO<sub>2</sub> powder – 1 mg/ml, 100 ml fungal suspension with cell density about 10<sup>4</sup> CFU/ml and BLB lamp (50 Hz 8W T5 with emission 365 nm) situated at distance 10 cm. At regular intervals of time, samples were taken and serial dilutions were prepared. The number of viable cells was detected by spread plate method. For determination of the post-irradiation effect, the treated suspensions were tested after 48 h dark period.

#### **Conclusions**

The data obtained about antifungal activity of TiO<sub>2</sub> are in agreement with photocatalytic properties of metal oxide nanoparticles. After 120 min UV-A photocatalytic treatment with 1 mg/ml TiO<sub>2</sub>, the number of colonies of *C.albicans* and *C.tropicalis* decrease from about 10<sup>4</sup> CFU/ml to less than 5 CFU/ml with 100% reduction index. Final reduction index in *C.lusitaniae* and *C.glabrata* is 99.643% and 99.898%, respectively. These data indicate strong photocatalytic fungicidal effect of TiO<sub>2</sub> on the tested fungi. At the same conditions, the colonies of *C.krusei* are reduced with 98%. Our data show that the nonhydrolytic synthesized nanosized TiO<sub>2</sub> possesses antifungal activity against isolates of the genus *Candida* with some differences in the speed of photocatalytic process.

### **CIPROFLOXACIN EFFECT ON SERUM OXALIC ACID LEVEL**

*B. Gülhan<sup>1</sup>, M. Aydın<sup>1</sup>, A. Çıkman<sup>1</sup>, A. Bozkurt<sup>2</sup>, M. Karabakan<sup>2</sup>, E. Hirik<sup>2</sup>, M. Günay<sup>3</sup>*

*<sup>1</sup>Medical Microbiology, Erzincan University Faculty of Medicine, Erzincan, Turkey*

*<sup>2</sup>Urology, Erzincan University Faculty of Medicine, Erzincan, Turkey*

*<sup>3</sup>Medical Biochemistry, Erzincan University Faculty of Medicine, Erzincan, Turkey*

### **Background**

Ciprofloxacin ranks among the primary drugs used as treatment in urinary system infections in adults.

It is known that *Oxalobacter formigenes* colonization in intestines is disrupted by antibiotic intake.

Due to the *Oxalobacter formigenes* colonization deficiency, the fact that high level serum oxalic acid

results in formation of renal calcium oxalate stones has been determined.

Additionally, serum oxalic

acid level increase is thought to have negative effect on urinary and cardiovascular system.

### **Objectives**

The purpose of our study is to search whether there is an increase in serum oxalic acid level because

of intestinal flora disorder in the patients with urinary system infection and the individuals given

ciprofloxacin as treatment.

### **Methods**

In our study, 40 people who have urinary system infection and take ciprofloxacin treatment have been included. Patients serum oxalic acid levels were evaluated both in pre-treatment and post-treatment evaluation which

was a month later. Serum oxalic acid was measured by a commercially available kit (SunRed Biological Technology, Serial number: 201-12-2153), using Human Oxalic Acid ELISA method.

### **Conclusions**

In conclusion, when pre-treatment and post-treatment serum oxalic acid levels were compared,

no statistical difference was found ( $p=0,47$ ). It was found that ciprofloxacin treatment didn't affect

serum oxalic acid levels of the patients with urinary system infection. In the light

of this data,  
it is concluded that these patients don't need to be followed up for any possible complications  
because of high level serum oxalic acid.

<sup>4</sup>Department for Microbiological Research,  
National Laboratory for Health Environment and Food & University of Maribor Faculty  
of Medicine & Cipkebip, Maribor, Slovenia

**Background**

Anaerobic bacterium *Clostridium difficile* has been traditionally considered as a human nosocomial enteropathogen. Although its natural habitat is human and animal intestine, the ability to form dormant endospores enables *C. difficile* to survive also in aerobic environment. Recent emergence of community acquired *C. difficile* infections and infections in animals implies that environment might be a reservoir of *C. difficile* and a source of infection.

**Objectives**

Our aim was to investigate diversity and overlap of *C. difficile* PCR-ribotypes isolated from animals and different non-hospital environments in Slovenia.

**Methods**

Strains included in the comparison originated from domestic animals (calves, piglets, horses, poultry and birds, goats, sheep, dogs and cats) and different environments (puddles and soil from rural and urban areas, compost and water from rivers and ponds) in Slovenia. Isolates were characterized by PCR-ribotyping and toxinotyping.

**Conclusions**

This work is unique in presenting a large number of *C. difficile* strains from several rural and urban environments and compare them to animal and human isolates. Altogether 80 PCR-ribotypes (47 in animals and 58 in the environment) were identified and 25 were shared between animals and the environment. Forty-six of

these PCR-ribotypes were found also in humans in Slovenia. Twenty-seven PCR-ribotypes were identified as non-toxigenic with more than half found only in the environment, mainly puddles and soil, which seem to represent an independent environment. Our results show that *C. difficile* genotypes that are commonly isolated from animals can also be isolated from different environments, indicating that non-hospital environment could represent an important reservoir.

## **TRANSPORT OF EUKARYOTIC CELLS THROUGH ELECTROHYDRODYNAMIC STRUCTURES**

A. Paulitsch-Fuchs<sup>1</sup>, A. Zsohar<sup>1</sup>, A. Zauner<sup>2</sup>, C. Kittinger<sup>2</sup>, G.E. Zarfel<sup>2</sup>, E.C. Fuchs<sup>3</sup>

<sup>1</sup>Department of Microbiology, Wetsus, Leeuwarden, Netherlands

<sup>2</sup>Institute of Hygiene Microbiology and Environmental Medicine,  
Medical University of Graz, Graz, Austria

<sup>3</sup>Applied Water Physics, Wetsus, Leeuwarden, Netherlands

### **Background**

When a high-voltage direct-current is applied to two beakers filled with water, a horizontal electrohydrodynamic (EHD) bridge forms between the two beakers. In this work we studied the transport and behavior of yeast cells and ThP1 human-monocytic-cell-line in this special environment.

### **Objectives**

The behavior of *Escherichia coli* in an EHD-bridge set-up was recently investigated: *E.coli* cells survive the procedure; the main direction of cell transport is from the cathode to the anode beaker. The goal of this work was to test in how far these results are specific for *E.coli*, thus studies with yeast cells and ThP1 cells were conducted.

### **Methods**

Cells were added to one or to both beakers, and the transport of the cells through the bridge was investigated using optical and microbiological techniques. One experimental series consisted of three different configurations: carrier solution in both beakers, only in the anode or only in the cathode beaker. As carrier solutions for yeast 5% glycerol and ThP1 cells 4.5% glucose were used.

### **Conclusions**

The behavior of cells in an EHD-bridge depends largely on their size and their surface charge. The heavier the organism, the slower the transport; the higher the surface charge, the more pronounced the preferred flow direction.

*S.cerevisiae*: transport was observed in both directions. The absence of a preferred flow direction means that electric forces play a smaller role which is corroborated by the zeta potential.

ThP 1 cells survive the transport and showed similar behavior as the *E.coli* cells: pronounced transport towards the anode.

**POST-ANTIBIOTIC AND POST-ANTIBIOTIC SUB-MINIMAL INHIBITORY  
CONCENTRATION EFFECTS OF CHLORHEXIDINE AGAINST ORAL BACTERIA**

M. You<sup>1</sup>, S. Lee<sup>1</sup>

<sup>1</sup>College of Dentistry, Gangneung-Wonju National University, Gangneung, Korea

**Background**

The post-antibiotic effect (PAE) is defined as the suppression of bacterial growth for a particular duration after a brief exposure to an antimicrobial agent. Chlorhexidine is a widely used biocide found in antiseptic products; however, its PAE remains unclear.

**Objectives**

In this study, PAE, post-antibiotic sub-minimum inhibitory concentration (MIC) effects (PA-SME), and sub-MIC effects (SME) of chlorhexidine on oral bacteria were investigated.

**Methods**

For PAE measurement, bacteria were exposed to 10x MIC chlorhexidine for 1 min, which was then eliminated by washing. For determining PA SME, bacteria were exposed to 0.1, 0.2, and 0.3x MIC chlorhexidine during the postantibiotic phase and to sub MIC chlorhexidine for measurement of SME. PAE, PA SME, and SME of chlorhexidine were observed.

**Conclusions**

The PAE lasted for 0.9 h for *Streptococcus mutans*, 0.1 h for *Streptococcus gordonii*, and 0.35 h for *Lactobacillus acidophilus*. The PA SME against oral bacteria lasted for longer duration as the chlorhexidine concentrations increased. The PA SME against oral bacteria lasted for substantially longer than SME did. The present study illustrates the existence of chlorhexidine-induced PAE, PA SME, and SME against oral bacteria, thereby extending the pharmacodynamic advantages of chlorhexidine.

## **PINWORM INFECTION AMONG FOREIGN LABORERS IN TAIWAN**

Y. Lo<sup>1</sup>, Y.L. Chen<sup>2</sup>, J.D. Wu<sup>3</sup>

<sup>1</sup>*Department of Family medicine,*

*Zouying Branch of Kaohsiung Armed Forces General Hospital, Kaohsiung, Taiwan*

<sup>2</sup>*Department of Laboratory Medicine,*

*Zouying Branch of Kaohsiung Armed Forces General Hospital, Kaohsiung, Taiwan*

<sup>3</sup>*Department of Occupational Safety and Health, Chang Jung Christian University, Tainan, Taiwan*

### **Background**

According to the demographic ageing of labor force participation in Taiwan, we imported massive foreign laborers to Taiwan for nursing or other labor force work since October, 1989. The purposes of this study was to evaluate the effectiveness of single examination to diagnose Enterobiasis by scotch tape perianal swab technique in non-constant time.

### **Objectives**

The survey covered southeast asian laborers from four countries including philippines, thailand, Indonesia and vietnam. The data were collected from 391 valid questionnaires, 391 valid stool samples and 391 valid scotch tape perianal swab samples.

### **Methods**

Single scotch tape perianal swab technique was performed by foreign laborers in non-constant time. Stool samples were also obtained after the scotch tape perianal swab. This was a cross-sectional study. Descriptive statistics were applied to the data.

### **Conclusions**

Scotch tape perianal swab technique in non-constant time could increase the detection rate of Enterobius vermicularis from 0% to 2.0%(8/391). Occupational health personnel should educate the foreign laborers to get into the habit of washing hands before a meal in their daily practice. The employers should arrange the examination of scotch-tape anal swab technique for caretakers periodically.

## **SPECIFIC KILLING OF BACTERIA USING A TOXIN-INTEIN BASED AND-LOGIC GATE**

R. López-Igual<sup>1</sup>, D. Mazel<sup>1</sup>

<sup>1</sup>*Genomes and Genetics, Institut Pasteur, Paris, France*

### **Background**

Synthetic biology aims reprogram bacteria to design and construct sophisticated new biological systems by gene regulatory networks. However gene regulatory networks (gene expression, protein or molecule concentration) are continuous, thus fitting them into a deterministic model like Boolean approximation (0/1) is noisy.

### **Objectives**

We would like to implement a model aiming at killing specific bacteria in mixed populations. We will design an AND-logic gate to solve Boolean satisfiability (SAT) problem. Our model is based on conjugation where plasmids will act as wires (plasmid inside cell is 1; no plasmid is 0).

### **Methods**

To avoid the noise associated with transcriptional regulators, our system is based on half toxins (thus non-functional) coupled with split intein technology. We are designing two types of plasmids: input plasmids (A and B) and clause plasmid (CP). Only CP is conjugative. A population of bacteria could have already implemented the input plasmids in different combinations: A and B; only A; only B or no one. The output in our system is *cell death*. The CP will infect these bacteria by conjugation and it will evaluate the inputs and will specifically kill bacteria harboring both plasmids (A and B). When both plasmids are together in the same cell, the expression of the toxin-intein fusion triggers the reaction between two inteins domains, allowing the reconstitution of the toxin and killing the cell.

### **Conclusions**

We have successfully completed the evaluation of Boolean-SAT problem by the construction of an AND-logic gate and using the inputs plasmids A and B, and the CP.

## **OUTBREAK OF BOTULISM IN MEMBERS OF A FAMILY FOLLOWING THE CONSUMPTION OF KUSHK**

M. Momen-Heravi<sup>1</sup>, R. Razzaghi<sup>1</sup>, E. Nasri<sup>1</sup>

<sup>1</sup>*infectious disease, Kashan University of Medical Sciences, Kashan, Iran*

### **Background**

Botulism is a serious neuromuscular disease caused by the *Clostridium botulinum*

### **Objectives**

In this article, we report an outbreak of the foodborne botulism due to consumption of kushk in 5 members of a family

### **Methods**

case presentation

A 41 and 46 year old women presented with diplopia and blurred vision from 4 days ago. She had progressive symptoms including dry mouth, dysphagia and swallowing disorder, constipation, dyspnea, general weakness of neck muscle and lower and upper limbs. Pupils were dilated and nonreactive to light. There was no gag reflex. Deep tendon reflexes were normal and the muscle force of upper limb was 4/5.

The third case was a 13 year old boy presented some days after two above mentioned cases. His complaints were ptosis, diplopia, dry mouth, vertigo and weakness of lower and upper limbs but had no constipation, dysphagia and swallowing disorder and dyspnea. The fourth case was a 12 year old boy with history of diabetes and similar symptoms and signs and the fifth case was an 8 year old girl with neck rigidity and ptosis.

They were members of a family and had history of consumption of kushk. Interval between involvement of children was longer than adult and incubation period. Disease was more severe in adult than children. EMG was done in one of the women and was suggestive of botulism. After clinical diagnosis, serum of patients was obtained and the patients received antitoxin. Their symptoms resolved gradually.

### **Conclusions**

The diagnosis of botulism should be made based on the patient's initial signs and symptoms and history of consumption of suspected food.

## **BLOOD BORN DISEASES IN INTRAVENOUS DRUG ABUSERS**

Z. Vakili<sup>1</sup>, M. Momen-Herav<sup>2</sup>, M. Moslemi<sup>3</sup>

<sup>1</sup>pathology, Kashan University of Medical Sciences, Kashan, Iran

<sup>2</sup>infectious disease, Kashan University of Medical Sciences, Kashan, Iran

<sup>3</sup>general practionner, Isfahan University of Medical Sciences, Kashan, Iran

### **Background**

Drug injection is responsible for numerous minor to life-threatening and fatal complications such as the transmission of human immunodeficiency virus (HIV), sexually transmitted diseases, and viral hepatitis

### **Objectives**

this paper has tried to offer a brief look at the epidemiology of drug abuse, while focusing on blood born infections seen in IDUs.

### **Methods**

The study was carried out using a cross sectional design. A questionnaire was distributed among 135 IDUs. serological tests (ELISA Anti HCV, Anti HIV, HBs Ag) were taken to confirm the existence of blood borne diseases

### **Conclusions**

A total of 135 cases between the ages of 15-57 were studied. opium was most frequently first drug used (58.5%), followed by cannabis (20.7%) and heroin (11.1%) .

nearly 68.9% of the population began abusing drugs before the age of 20. 61.4% of the cases had a history of sharing needles Other results showed that 51.5% had an accompanying blood borne disease. Further analysis indicated a meaningful relationship ( $P < 0.001$ ) between needle sharing and accompanying blood borne diseases. Of the 51.5% who had an accompanying blood borne disease, 17.1% were found to have either reactive ELISA of AntiHIV alone, or in combination with Hepatitis. In other words, it can be concluded that 8.1% of the total population had reactive ELISA of AntiHIV. Results also showed that 11.1% of the total population had HBs Ag positive while 47.4% had Positive ELISA Anti HCV

## **MICROBIAL CAUSES OF WOUNDS AND SKIN INFECTIONS IN INJECTING DRUG USERS**

M. Momen-Heravi<sup>1</sup>, Z. Vakil<sup>2</sup>, M. Moslem<sup>2</sup>

<sup>1</sup>*infectious disease, Kashan University of Medical Sciences, Kashan, Iran*

<sup>2</sup>*infectious pathology, Kashan University of Medical Sciences, Kashan, Iran*

### **Background**

60–80% of hospital admissions in IV drug abusers are due to infectious complications and skin and soft-tissue infections seem to be some of the most common infections among this group

### **Objectives**

The goal of this study was to identify the characteristics of wounds and skin infections of this group to hopefully have early recognition and as a result better prevention and management strategies

### **Methods**

This descriptive cross sectional study was carried out on 135 IDUs . . all current injection drug users who had at least one wound as a result of injecting drugs were enrolled in this study. the wounds were physically examined and smear samples were also cultivated on Blood Agar and EMB Agar environments for microbiological assessments

### **Conclusions**

A total of 135 cases between the ages of 15-57 were studied. T. Most wounds (45.2%) were located in the lower limbs such as the foot, . the majority (44%) of wounds were as old as six months up to one year. each individual had at least 4 wounds with an average size of 1.8 cm<sup>2</sup>. 22.2% of the population had some form of infection such as abscess or cellulites. Thrombophlebitis was seen in 37% and. Only 10.4% showed necrotizing ulcers .

Microbiological assessments found that the majority of wounds (54.1%), had gram positive cocci. This included staphylococcus (36.3%), streptococcus (17.8%). 7.4% of the cases showed gram negative species. 30.4% of the bacterial cultures showed negative or nontypable results, since the culture environments used were very routine and non-specific. Fungi were seen in 8.1% of the cases

### **Background**

Pneumonia is also a major cause of prolonged hospitalization, mortality and morbidity among HIV infected people that costs millions each year

### **Objectives**

the goal of this study was determine of outcome and prognostic factors of pneumonia in HIV positive individuals.

### **Methods**

In a descriptive method, 80 HIV positive patients that hospitalized in Loghman-hakim hospital between 2005 to 2011 with pneumonia have been studied and their demographic findings include age ,sex, marriage, job, social history such as smoking, Iv drug using and imprisonment, medical history of co infections such as pulmonary TB, HCV and HBV, and also clinical features include their initial signs and symptoms ,lab data and imaging, and at last their outcome gathered and record in questionnaire. Then gathered data enter SPSS#13 software, analyzed by descriptive tests

### **Conclusions**

80 HIV positive patients hospitalized with pneumonia in loghman-hakim hospital since 2005 to 2011 entered the study. Mean age was 37.4(±8.2) years. death was the first with 43.8% , then recovery with 30% and pulmonary complications with 16.3% were the most common outcomes. Mortality was more common in the elderly .Most of the patients had history of smoking,injection drug use and. imprisonment history and mortality rate in these patients were more common. The mortality rate was also more common in patients with anemia, high ESR levels, CRP + , high urea and high creatinine levels and low CD<sub>4</sub> counts and pleural effusion.

## **SCREENING OF SIDEROPHORE BIOSYNTHESIS GENES FROM SIDEROPHORE PRODUCING ACTINOMYCETES**

*I. Kaweewan<sup>1</sup>, W. Pathom-aree<sup>1</sup>*

<sup>1</sup>*Biology, Chiang Mai University Faculty of Science, Chiang Mai, Thailand*

### **Background**

Iron is an essential trace element required for growth of all microorganisms. However, iron in environment is mostly insoluble form and cannot be readily utilized by microorganisms. In iron starvation condition, actinomycetes have developed specific mechanisms involving in the production of small organic metal chelator called siderophore.

### **Objectives**

Actinomycetes were isolated from coastal and mangrove sediments in Thailand. Genomic DNA were extracted by phenol-chloroform method. Hydroxamates and catecholate siderophore biosynthetic genes were detected by PCR using *desD* and *entF* specific primers, respectively. Siderophore production was determined by CAS assay. Siderophore producing actinomycetes were identified by 16S rRNA gene sequence analysis.

### **Methods**

A 1.2 kb fragment of *desD* gene that encodes for desferrioxamine, a hydroxamate siderophore was detected in 7 isolates. A 203 bp amplified fragment of *entF* gene encoding enterobactin, a catecholate siderophore was detected in 3 isolates. All isolates produced siderophore on Chrome Azurol S agar. High siderophore producing *Streptomyces parvulus* S2-SC3 was selected for sequence analysis of *desD* gene. A 1.2 kb amplified PCR fragment showed 90% sequence similarity with desferrioxamine synthetase from *Streptomyces lividans* strain 1326. Phylogenetic analysis revealed that these siderophore producing actinomycetes were members of the genus *Micromonospora*, *Streptomyces* and *Verrucosispora*.

### **Conclusions**

PCR offers a fast way to screen for siderophore producing actinomycetes. However, some producing strains were failed to detect by our PCR screening, several actinomycetes strains may carry diverse siderophore biosynthesis gene which could not be detected by currently available primers. Our results suggested that novel siderophore may exist in these actinomycetes.

## **TAXONOMIC DIVERSITY OF ACTINOMYCETES FROM THAI MANGROVE SEDIMENTS**

*P. Suksaard<sup>1</sup>, R. Srivibool<sup>2</sup>, K. Duangmal<sup>1</sup>, W. Pathom-aree<sup>3</sup>*

<sup>1</sup>*Microbiology, Kasetsart University, Faculty of Science, Bangkok, Thailand*

<sup>2</sup>*Marine Science, Burapha University, Chonburi, Thailand*

<sup>3</sup>*Biology, Chiang Mai University Faculty of Science, Chiang Mai, Thailand*

### **Background**

Actinomycetes are large group of high GC Gram positive bacteria that widely distributed in nature. They have proved to be an important source for industrially useful bioactive metabolites, notably antibiotics. In Thailand, there are very few studies on microbial diversity in mangrove forests. In this study, we report on the diversity of cultivable actinomycetes in mangrove sediments and provide taxonomic evidence of their novelty taxa.

### **Objectives**

Actinomycetes were isolated from mangrove sediments and taxonomically characterized. Representative isolates were selected and identified based on 16S rRNA gene sequence analysis. Putative novel taxa were subjected to polyphasic taxonomic characterization using standard methods.

### **Methods**

Over 100 strains of actinomycetes were isolated from mangrove sediments using media selective for actinomycetes. Phylogenetic analyses based on a 16S rRNA gene sequences showed that the majority of isolates were dominated by genus *Streptomyces*. In addition, members of the genera *Amycolatopsis*, *Jiangella*, *Micromonospora*, *Nocardia* and *Verrucosipora* were also found. Some isolates may represent a new species. For example, *Jiangella* strain 3SM4–07<sup>T</sup> was most closely related to *Jiangella alkaliphila* JCM 15620<sup>T</sup> (99.0%), However, they shared mean DNA–DNA hybridization values of only 31.5±2.6%.

### **Conclusions**

Our results provide further evidence that mangrove sediments harbor taxonomically diverse actinomycetes. The diversity of these organisms and their novelty support the view that this under studied habitat is a rich source of novel actinomycetes which can be further exploited for biotechnological purposes.

<sup>3</sup>Forest and Plant Conservation Research Office,  
Department of National Parks Wildlife and Plant Conservation, Bangkok, Thailand

<sup>4</sup>Biology, Chiang Mai University Faculty of Science, Chiang Mai, Thailand

### **Background**

Eucalyptus are the most important raw material supply for pulp industries in Thailand. Leaf and shoot blight caused by *Cryptosporiopsis eucalypti*, *Cylindrocladium* sp. and *Teratosphaeria destructans* is a serious disease in eucalypt plantations. The search of actinomycetes for biological control agents is one of the promising approaches.

### **Objectives**

In this study, we isolated actinomycetes capable of inhibiting the growth of fungal pathogens causing leaf and shoot blight on eucalyptus. The potential strain to use as biocontrol agent was selected for further study.

### **Methods**

Actinomycetes were isolated from roots and rhizospheric soil of eucalyptus using starch casein agar and humic acid-vitamin agar supplemented with antimicrobial antibiotics. The isolates were screened for their ability to inhibit eucalyptus fungal pathogens using dual culture technique.

### **Conclusions**

A total of 478 actinomycete strains were successfully isolated from roots (95 isolates) and rhizosphere soil (383 isolates) of eucalyptus. Among these, 439 isolates (91.8%) were streptomycetes and 39 isolates (8.16%) were non-streptomycetes. All isolates were evaluated for their *in vitro* antagonistic effect on plant pathogenic fungi. The result showed 273, 120 and 241 isolates were antagonistic to *Cryptosporiopsis eucalypti*, *Cylindrocladium* sp. and *Teratosphaeria destructans*, respectively. Among these, 48 isolates (10%) displayed activity against all three fungal pathogens. The isolate EUSKR2S82 showed the strongest inhibitory effects against all tested fungi.

The identification of this strain using 16S rRNA genes sequence revealed that isolate EUSKR2S82 shared 99.4% similarity with *Streptomyces ramulosus* NRRL B 27-14<sup>T</sup>.

## **CULTIVABLE ACTINOMYCETES ASSOCIATED WITH GLOMUS MOSSEAE SPORES AND THEIR PLANT GROWTH PROMOTING ACTIVITY**

*K. Lasudee<sup>1</sup>, W. Pathom-aree<sup>1</sup>*

<sup>1</sup>*Biology, Chiang Mai University Faculty of Science, Chiang Mai, Thailand*

### **Background**

Actinomycetes are prolific producers of bioactive compounds. Much of our research effort has been directed at assessing the diversity of actinomycetes in various environments. Currently, we are interested in mycorrhizal helper bacteria which may be a good source for novel taxa for bioprospecting.

### **Objectives**

In this study, we report on the isolation of actinomycetes from spores of *Glomus mosseae* and provide preliminary evidence of their potential in agriculture as plant growth promoter.

### **Methods**

Actinomycetes were isolated from spores of *Glomus mosseae* using the dilution plate technique and media designed for the selective isolation of members of specific actinomycete taxa. All isolates were identified by 16S rRNA gene analyses. The isolates were examined for their ability to produce indole-3-acetic acid, siderophores and solubilize phosphate *in vitro*.

### **Conclusions**

Six strains were isolated from spores of *Glomus mosseae* using media selective for actinomycetes. Phylogenetic analyses based on a 16S rRNA gene sequences showed that the isolates belonged to the genera *Lysibacter* and *Streptomyces*. All isolate produced siderophore, four isolates produced IAA and two isolates solubilized phosphate at varying level. *S. thermocarboxydus* S3 produced 11.23±0.02 mg/ml IAA and high activity of phosphate solubilization and siderophore production. The results provide evidence that actinomycetes were associated with arbuscular mycorrhizal spores of *Glomus mosseae*. The ability of these organisms to produce plant growth promoting agents support the possibility of using these actinomycetes for agricultural purposes.

**PROFERROROSAMINE A SECRETION BY ERWINIA RHAPONTICI P45 INHIBITS GROWTH OF THE FIRE BLIGHT PATHOGEN ERWINIA AMYLOVORA**

C. Pelludat<sup>1</sup>, Y. Born<sup>2</sup>

<sup>1</sup>Agroscope, Institute for Plant Production Sciences IPS, Wädenswil, Switzerland

<sup>2</sup>Zurich University of Applied Sciences, Institute of Food and Beverage Innovation, Wädenswil, Switzerland

**Background**

The classic diagnosis of the fire blight pathogen *E. amylovora* (EA) takes the cell morphology on King's B agar into account. Sometimes, an unusual pink coloration of EA colonies can be observed on this agar. This coloration is due to the co-cultivation of *E. rhapontici* or *E. persicina* and their production of the iron (Fe<sup>2+</sup>) chelator proferrosamine A (pFRA), that accumulates in *E. amylovora*. Dependent on the proximity of a pFRA synthesizer, EA colonies can also exhibit an attenuated growth.

**Objectives**

To get a deeper insight into the mechanism of the Fe<sup>2+</sup> chelator, we aimed to identify the genes involved in proferrosamine A synthesis.

**Methods**

pFRA negative mutants of *E. rhapontici* P45 were isolated in a phenotypic transposon mutagenesis screen.

**Conclusions**

We identified a 9.3 kb cluster of seven genes that encode proteins involved in pFRA synthesis. Wild type *E. rhapontici* P45, but not pFRA negative mutants, showed a growth inhibition effect on EA *in vitro* and detached flower assay.

**COMBINED EFFECT OF OSMOTIC AND UV-B IRRADIATION ON A N<sub>2</sub> FIXING  
CYANOBACTERIUM FROM A RICE PADDY**

G. Pérez<sup>1</sup>, S. Doldán<sup>2</sup>, P. Scavone<sup>3</sup>, O. Borsani<sup>2</sup>, P. Irisarri<sup>1</sup>

<sup>1</sup>Microbiology, Facultad de Agronomía, Montevideo, Uruguay

<sup>2</sup>Biochemistry, Facultad de Agronomía, Montevideo, Uruguay

<sup>3</sup>Microbiology, Instituto Investigaciones Biológicas Clemente Estable, Montevideo, Uruguay

**Background**

Cyanobacteria play a crucial role in the productivity of terrestrial and aquatic systems and have developed a series of defense mechanisms against abiotic factors as UV-B light and osmotic stress.

**Objectives**

In order to study the protective strategies of *Calothrix* B122 spp., this cyanobacterial isolate from a subtropical rice field was exposed to low doses of UV-B alone or in combination with osmotic stress.

**Methods**

After the stress exposure, oxidative damage was determined by TBARS and proline accumulation quantified. The activity of enzymes (superoxide dismutase and catalase) involved in the decrease of reactive oxygen species (ROS), O<sub>2</sub><sup>-</sup> or H<sub>2</sub>O<sub>2</sub>, were determined and the *in vivo* production of ROS was followed by confocal microscopy. Photosystem II yield and O<sub>2</sub> photoevolution were also studied as proxies of the effect of the stress on the cyanobacterium physiology.

**Conclusions**

Osmotic stress, in general, caused a more pronounced oxidative damage but in combination with UV-B the damage drastically increased. Among the enzymes involved in the antioxidant defense, CAT had a higher activity under osmotic stress but in the presence of both types of stresses its activity doubled. SOD, on the other hand, had higher rates only under UV-B light. The accumulation of ROS followed a similar pattern as the antioxidant enzymes studied. Photosynthesis was affected in all of the situations studied. This study showed that this cyanobacterium had a differential response when exposed alone to each type of stress than in combination.

## **TAILORING AGAROSE WITH PENDANT GROUPS FOR DISTINCT DNA FRAGMENT ANALYSIS IN GEL ELECTROPHORESIS**

*H.J. Kim<sup>1</sup>, Y.G. Kim<sup>1</sup>, J. Jeong<sup>1</sup>, H.W. Ryu<sup>1</sup>*

*<sup>1</sup>Chemical Engineering, Soongsil University, Seoul, Korea*

### **Background**

Agarose gel electrophoresis has been widely used as the standard method to separate, identify, and purify DNA/RNA fragments in the life sciences research, because it's easy to perform, relatively inexpensive, and excellent in analytical performance characteristics. However, technologies to separate for short DNA fragments in high resolution are still lacking.

### **Objectives**

In response to the above challenge, we hypothesized that the tailoring agarose molecules with various pendant groups would provide the rapid analysis of an array of small to large DNA fragments in the gel electrophoresis.

### **Methods**

We examined this hypothesis by tailoring the agarose molecules with various pendant groups such as octadecyl chains, and aromatic groups, and then directly fabricate the three dimensional agarose gel for electrophoresis. This concept of the hydrophobically-modified 3D microporous gel can be regarded also as a novel microfluidic-based mold for being demonstrated and also used in the bio-microelectromechanical system (Bio-MEMS). The molecular structure (degree of substitution and molecular weight) of the modified agarose was confirmed by <sup>1</sup>H-NMR, and MALDI-TOF (Matrix: CHCA) analysis. Interestingly, the tailoring agarose gel provided the distinctive separation of small DNA fragments efficiently and also enhanced the discriminatory power in the gel electrophoresis based on the pendant groups' characteristics.

### **Conclusions**

Overall, the results from this study may be useful in understanding the role of the hydrophobic/hydrophilic balance in the separation of DNA fragments and further in the extracellular microenvironments in tuning a variety of cellular activities.

**TEMPERATURE- AND NITROGEN SOURCE-DEPENDENT GROWTH OF  
LISTERIA MONOCYTOGENES IMPLICATES AN IMPORTANT ROLE OF 2-  
OXOGLUTARATE AS INTERNAL SIGNAL DURING ADAPTATION TO CHANGING  
ENVIRONMENTS**

J. Schardt<sup>1</sup>, F. Schindele<sup>2</sup>, S. Scherer<sup>1</sup>, S. Müller-Herbst<sup>1</sup>

<sup>1</sup>Mikrobiologie,

Zentralinstitut für Ernährungs- und Lebensmittelforschung TU München, München,  
Germany

<sup>2</sup>Hygiene und Medizinische Mikrobiologie, Max von Pettenkofer-  
Institut LMU München, München, Germany

**Background**

The pathogen *Listeria monocytogenes* lives either saprophytically in the environment or within cells in the vertebrate host. Thus it has to adapt its lifestyle to its ecological niche and the availability of nutrients.

**Objectives**

The aim of this study was to investigate the impact of different nitrogen sources and temperatures on growth of *L. monocytogenes*.

**Methods**

Nitrogen source dependent growth analysis was conducted in defined minimal medium at 24°C or 37°C with either glutamine or ammonium as nitrogen source. Nitrogen source- and temperature-dependent gene transcription was validated by qPCR.

**Conclusions**

A preference for ammonium over glutamine was observed in growth experiments. This might be ascribed to the interrupted TCA cycle in *L. monocytogenes*, causing accumulation of the intermediate 2-oxoglutarate. 2-oxoglutarate has to be removed to allow a permanent glucose metabolism by continuous channeling of pyruvate in the TCA cycle. During growth on ammonium twice the amount of 2-oxoglutarate is removed compared to growth on glutamine.

Reduced growth on glutamine was more obvious at 24 °C than at 37 °C. When grown on the same nitrogen source, but at different temperatures, the removal of 2-oxoglutarate is mainly determined by the amount of glutamate used for the *de novo* biosynthesis of amino acids which is expected to be elevated at the optimal growth temperature of 37 °C.

It is assumed that in *L. monocytogenes* the intracellular 2-oxoglutarate concentration serves as internal signal that allows the adaptation of *L. monocytogenes* to two environmental parameters, temperature and nitrogen source, at the same time.

## **INVESTIGATION OF AUTOANTIBODIES IN CANCER PATIENTS**

A. Sener<sup>1</sup>, F. Tarhan<sup>2</sup>

<sup>1</sup>*Medical Microbiology, Izmir Katip Çelebi University, Izmir, Turkey*

<sup>2</sup>*Rheumatology, Izmir Katip Çelebi University, Izmir, Turkey*

### **Background**

Malignant diseases are often related with the induction of autoimmunity, characterized by the generation of autoantibodies against a wide range of autoantigens. Serum autoantibodies have been identified in patients with solid tumors and in patients with hematological malignancies.

### **Objectives**

The purpose of the study was to investigate the prevalence of antinuclear antibodies (ANA) in sera of the patients with various cancer types.

### **Methods**

Serum samples were obtained from 54 patients with cancer (37 breast, 1 *myxoid liposarcoma*, 1 brain, 2 lung, 1 colon, 3 gastric, 1 pancreas, 2 lymphoma, 1 multiple myeloma, 1 nasopharynx, 1 renal, 1 prostate, 1 vulva, 1 endometrial) and with rheumatic complaint. A total of 100 healthy blood donors served as the study control group. ANA patterns were searched by using the HEp-2010/Liver (Monkey) indirect immunofluorescence assay (IFA) kit (Euroimmun AG, Germany). In addition these samples were further processed by line immunoassay (LIA), (Euroimmun AG, Germany).

### **Conclusions**

Of 54 patients, 18 were ANA-positive by IFA and LIA. Homogen (8), granular/speckled (2), nucleolar (2), anticontromere (2) and mixed (4) patterns were detected by IFA. SS-A/Ro (8), SS-B/La (6), antidsDNA (2), antiSci (2) and CENP-B (2) positivity were observed by LIA. In healthy control group, ANA was not detected. There was statistically significant difference between the results of the patients and of the control group. Of 54 patients, 29 were diagnosed with cancer while 20 were diagnosed with rheumatic disease firstly; and 5 were diagnosed with both simultaneously. In

conclusion, the association between rheumatic diseases and malignant diseases need further investigation.

## **ANTI-DFS70 ANTIBODIES IN 500 HEALTHY BLOOD DONORS**

A. Sener<sup>1</sup>, B. Peker<sup>1</sup>, B. Uzun<sup>1</sup>, I. Afsar<sup>1</sup>

<sup>1</sup>*Medical Microbiology, Izmir Katip Çelebi University, Izmir, Turkey*

### **Background**

Autoantibodies against DFS70 (dense fine speckled 70) antigen have been recently identified among the antinuclear antibodies (ANAs) in patients with systemic autoimmune rheumatic diseases.

### **Objectives**

The typical DFS has been described as indirect immunofluorescence (IIF) staining pattern which is uniformly distributed throughout the interphase nucleus and, most notably, are localized on metaphase chromosomes. We undertook this study to examine the frequency of anti-DFS70 antibodies in a large number of healthy blood donors and to evaluate the significance of these antibodies, accordingly.

### **Methods**

Sera of 500 healthy blood donors (459 men, 41 women) were analyzed for ANAs and anti-DFS70 antibodies by IIF with HEP-2 cells as a substrate.

### **Conclusions**

ANAs were determined in 0.8% of all blood donors by IIF. Positive results were detected in different serum dilutions: Three subjects (0.6%) 1:320 nucleolar pattern, and 1 subject (0.2%) 1:1000 homogeneous/nucleolar pattern. There were 3 anti-DFS70 antibody positive blood donors. In this study, anti-DFS70 autoantibody was detected 0.6% in healthy blood donors. Among anti-DFS70 antibody-positive subjects the percentage of male was 0.65% (3 of 459 subjects). The prevalence of anti-DFS70 antibody positivity decreased with increasing age. According to our results, anti-DFS70 autoantibody is detected more commonly in male than female healthy blood donors. More comprehensive studies are needed to be done to investigate the anti-DFS70 autoantibody specificity for healthy individuals.

**FEMS-1166**  
**Free subjects**

## **ANTI-DFS70 ANTIBODIES IN SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES**

*B. Peker<sup>1</sup>, A. Sener<sup>1</sup>, F. Tarhan<sup>2</sup>, B. Uzun<sup>1</sup>, S. Kaya<sup>1</sup>*

*<sup>1</sup>Medical Microbiology, Izmir Katip Çelebi University, Izmir, Turkey*

*<sup>2</sup>Rheumatology, Izmir Katip Çelebi University, Izmir, Turkey*

### **Background**

Systemic autoimmune rheumatic diseases are major cause of morbidity and mortality. The presence of various autoantibodies, such as antinuclear antibodies produced against intracellular antigens, are characteristic of systemic autoimmune rheumatic disease (SARD).

### **Objectives**

In this study, we aimed to investigate the prevalence of anti- DFS70 antibodies in SARD and to evaluate the significance of these antibodies, accordingly.

### **Methods**

In our study we created test groups as; 107 healthy blood donors, 418 Rheumatoid arthritis (RA), 101 Systemic Lupus Erythamatosus (SLE) patients, 36 Systemic sclerosis patients, 71 Sjögren syndrome patients, 43 Ankylosing spondylitis and 2555 Connective tissue disease (CTD) pre-diagnosed patients. Serum samples were evaluated by indirect immunofluorescence assay (IFA). Anti-DFS70 positive samples were also tested by ELISA test.

### **Conclusions**

Anti DFS70 antibody was detected 1.4% in RA, 2.97% in SLE, 1.4% in Sjögren syndrom and 1.05% in disease group with pre-diagnosed CTD. It was not detected in AS and SSc patient groups. Totally 39 out of 47 samples were also found to be anti DFS70-positive by ELISA method. According to our results, anti-DFS70 autoantibody is detected more commonly in certain disease sub-groups of SARD than healthy individuals.

## **NONTOXIGENIC CLOSTRIDIUM DIFFICILE MEMBRANE FRACTION AS A VACCINE CANDIDATE**

M. Senoh<sup>1</sup>, M. Iwaki<sup>1</sup>, A. Yamamoto<sup>1</sup>, H. Kato<sup>1</sup>, T. Fukuda<sup>1</sup>, K. Shibayama<sup>1</sup>

<sup>1</sup>Bacteriology II, National Institute of Infectious Diseases, Tokyo, Japan

### **Background**

*Clostridium difficile* is a leading cause of infectious diarrhea and pseudomembranous colitis. Standard treatment for *C. difficile* infections (CDI) includes the administration of antibiotics. However, the rate of CDI recurrence after initial therapy is approximately 20% and even increases when antibiotic therapy is repeated.

### **Objectives**

Therefore, alternatives or additional measures to current antibiotic therapy are required to achieve lower rates of CDI recurrence. Vaccination is one of prevention measures by which low recurrence rate is expected. In this study, we demonstrate the potential of nontoxigenic *C. difficile* membrane fraction (ntCDMF) as a vaccine candidate.

### **Methods**

Mice immunized with ntCDMF showed serum IgG and intestinal IgA titers of 4,660 and 156, respectively, as compared to 30 and 13, respectively, for non-immunized controls. In Caco-2 cell adhesion assay for 9 different *C. difficile* strains, the number of adherent bacterial cells pretreated with the immune serum was 5.8–9.3 CFU per 100 Caco-2 cells, which was significantly lower than in the case treated with non-immunized serum (21.1 to 36.6). Similar findings were observed for intestinal fluid, where the number of adherent bacterial cells ranged from 19.6 - 29.1 and 25.9 - 42.0 CFU per 100 Caco-2 cells for immunized and control mice, respectively.

### **Conclusions**

These results support the idea of ntCDMF-derived *C. difficile* vaccine capable of preventing the adhesion for *C. difficile* to the intestinal cells, as well as emphasize its potential as a preventive measure against CDI.

## **TOXICITY AND ANTIBACTERIAL ACTIVITY OF CYANOBACTERIAL STRAINS ISOLATED FROM SERBIAN FRESHWATERS**

J. Simeunovic<sup>1</sup>, O. Babic<sup>1</sup>, D. Kovac<sup>1</sup>, Z. Svircev<sup>1</sup>

<sup>1</sup>Department of Biology and Ecology, Faculty of Sciences-University of Novi Sad, Novi Sad, Serbia

### **Background**

This paper reviews the toxicity and antibacterial activity of ten cyanobacterial strains isolated from fresh waters in Serbia.

### **Objectives**

All investigated cyanobacterial strains showed toxic effect to *A. salina*. The highest toxicity was observed in the case of strains belonging to *Microcystis* genera (*Microcystis* L1 and P1) with detected larval mortality of 98% and 96%, respectively. The observed LD50 values were from 0.24 mgml<sup>-1</sup> (*Anabaena* P1) to 3.37 mgml<sup>-1</sup> (*Oscillatoria* K3). The intracellular microcystin concentrations, calculated as microcystin-LR equivalents, were in the range of 0.1–3.96 µgmg<sup>-1</sup> dry weight. All cyanobacterial strains revealed antibacterial activity and inhibited the growth of at least one bacterial species. The intracellular extract of *Aphanizomenon* K2 strain showed the most evident inhibitory effects to 6 bacteria. The MIC values of the tested strains were in the range of 0.00014 gL<sup>-1</sup> - 0.5805 gL<sup>-1</sup>.

### **Methods**

The toxicity of intracellular extracts of cyanobacterial strains was tested by *Artemia salina* bioassay and expressed as the percentage of larval mortality. The intracellular hepatotoxin (microcystin) content of cyanobacterial strains was determined by colorimetric protein phosphatase 1 inhibition assay (PP1). Methanolic intracellular extracts of cyanobacterial strains were tested for antibacterial activity using agar diffusion method and broth microdilution assay.

### **Conclusions**

The results suggest that toxic effect on larvae *A. salina* found in the most tested strains is likely to be a consequence of their microcystin production. The obtained results indicate that toxins are probably not responsible for the expressed antibacterial activity of the tested strains.

## **LABELLING OF EICOSAPENTAENOIC ACID WITH STABLE ISOTOPE ( $^{13}\text{C}$ ) IN BACTERIA**

*J. Tejerina<sup>1</sup>, J. Ryan<sup>2</sup>, M. Vyssotski<sup>2</sup>, K. Lagutin<sup>2</sup>, G. Visnovsky<sup>1</sup>*

<sup>1</sup>*Chemical and Process Engineering, University of Canterbury, Wellington, New Zealand*

<sup>2</sup>*IBT, Callaghan Innovation, Wellington, New Zealand*

### **Background**

Eicosapentaenoic acid (EPA) is an essential omega-3 polyunsaturated fatty acid (PUFA) well known for its beneficial effects on human and animal health.

EPA is present at relatively high levels in a number of marine animals with its primary dietary source being microalgae and some bacteria. This essential bioactive plays a critical role in marine life; however its transfer between different trophic levels is yet to be fully understood.

### **Objectives**

A simple and affordable method to study and trace the fate of EPA through the trophic food chain was developed.

### **Methods**

*Shewanella* sp. is a marine bacterium, known to produce EPA [1, 2]. In this work, we describe a simple method to label the EPA present in the bacterial strain IRL 567 (*Shewanella* sp.) with the stable isotope  $^{13}\text{C}$ . Labelling assays were performed at small scale (100 ml shake flask) and bench scale (1lt stirred tank bioreactor). By incubating the bacteria with  $^{13}\text{C}$ -acetate in culture medium, we demonstrated that EPA is *de-novo* synthesized utilizing the simplest carbon source -acetate- as precursor.  $^{13}\text{C}$  incorporation into the EPA molecule was determined by mass spectrometry (ESI TOF MS), finding that 95.5% of synthesized EPA being labelled in the shake flask and 88.6% in the bioreactor, yielding a concentration of labelled EPA of 5.36 mg/l and 2.90 mg/l, respectively, with between 2 to 8  $^{13}\text{C}$  atoms contained in EPA structure.

### **Conclusions**

Labelled EPA could be a valuable research tool to understand the assimilation and metabolic routes of fatty acids, essential components in human and animal diets.

**BLOODSTREAM FUNGAL ISOLATES DURING 8-YEAR PERIOD: 2007-2014**

*T. Tosic<sup>1</sup>, M. Jovanovic<sup>1</sup>, Z. Varagic Stojanovic<sup>1</sup>, B. Stosovic<sup>1</sup>, B. Lukovic<sup>1</sup>,  
S. Tomanovic<sup>1</sup>, S. Stefanovic<sup>1</sup>, D. Ilic<sup>1</sup>, M. Radic Sekeres<sup>1</sup>, S. Jovanovic<sup>1</sup>*

*<sup>1</sup>Bacteriology Laboratory, Clinical Center of Serbia, Belgrade, Serbia*

**Background**

The occurrence of candidemia is on a rise worldwide. Non-albicans *Candida* species have emerged as major causes of candidemia in many countries. Added to it is the problem of antifungal resistance in *Candida* isolates.

**Objectives**

The aim of our study was to investigate the isolation of *Candida* spp in blood cultures and to evaluate their antifungal susceptibility during a 8-year period (2007-2014) in a tertiary care hospital.

**Methods**

The blood cultures were incubated in the automated blood culture system BACTEC9240 (Becton Dickinson). Positive blood cultures were examined microscopically directly for yeast or pseudohyphae and subcultured on Sabouraud dextrose agar (Liofilchem Italy). *Candida* isolates were identified using automated VITEK 2 system (bioMérieux) or Api 20CAUX (bioMérieux). Antifungal susceptibility was carried out by automated VITEK 2 system (bioMérieux) using AST Y01 or AST Y07 test card.

**Results:** During the study period there were 67 candidemia cases. The 51.35% of candidemias occurred in the ICUs, the 40.54% in the medical wards and the rest of 8.11% in surgical wards. *C. parapsilosis* was the predominant species (35.15%), followed by *C. albicans* (32.43%), *C. glabrata* (10.81%), *C. tropicalis* (8.12%) and *C. norvegensis*, *C. guilliermondii*, *C. kefyr*, *C. famata*, *Cryptococcus neoformans* with (2.70%). All tested isolates were susceptible to amphotericin B and voriconazole. Among non-albicans strains increasing resistance to fluconazole was found: *C. parapsilosis* (8.33%), and *C. tropicalis* (8.33%).

**Conclusions**

Candidemia was more frequent in ICUs followed by medical and surgical wards. *C. parapsilosis* was the predominant cause of candidemias in our Hospital. Amphotericin B and voriconazole were active against all tested isolates.

**ASSESSMENT OF IMMUNE PROTECTIVE CAPACITY OF THE RECOMBINANT IRON SUPEROXIDE DISMUTASE (FESOD) FROM BORDETELLA PERTUSSIS**

C. Yılmaz<sup>1</sup>, A. Apak<sup>2</sup>, E. Ozcengiz<sup>3</sup>, G. Ozcengiz<sup>1</sup>

<sup>1</sup>Biology, Middle East Technical University, Ankara, Turkey

<sup>2</sup>Department of Dermatology Venerology and Allergology, Charité-Universitätsmedizin Berlin, Berlin, Germany

<sup>3</sup>Çerkezköy Production Plants, Deva Holding, Tekirdağ, Turkey

**Background**

Whooping cough (pertussis) is a highly contagious respiratory infection caused by *Bordetella pertussis*. Although availability of effective pertussis vaccines seems to decrease the incidence of the disease, *B. pertussis* circulation in population has not been eliminated. Thus, finding new protein candidates with high immune protective capacities is necessary to enhance the efficacy of current acellular pertussis (Pa) vaccines (1).

**Objectives**

The aim is to evaluate immune protective capacity of iron superoxide dismutase (FeSOD) protein from *B. pertussis* with the aim of developing new generation pertussis vaccines.

**Methods**

FeSOD gene was cloned, expressed in *Escherichia coli* and the recombinant protein was purified. FeSOD was formulated with Aluminum hydroxide (Alum) or Monophosphoryl Lipid A (MPLA) and mice were immunized intraperitoneally. IgG1, IgG2a and IFN- $\gamma$  levels were determined and bacterial colonization on mice lungs were evaluated.

**Conclusions**

IgG1 and IgG2a responses were significantly increased in both mice groups immunized with FeSOD-Alum and FeSOD-MPLA, the level of IgG2a was relatively higher in mice vaccinated with FeSOD-MPLA. Immunization with FeSOD-MPLA formulation provided a significant decrease in bacterial count in mice. Moreover, antigen specific-IFN- $\gamma$  response was significantly increased in the group vaccinated with FeSOD-MPLA. These findings, altogether, suggested that the recombinant FeSOD protein formulated with MPLA can be a possible acellular pertussis vaccine candidate.

**Background**

MIRRI (Microbial Resources Research Infrastructure, [www.mirri.org](http://www.mirri.org)) is an initiative within the European Strategy Forum on Research Infrastructure (ESFRI) that includes 16 partners (14 public microbial Culture Collections / mBRCs), supported by 21 collaborators; the preparatory phase is currently funded by the European Commission.

MIRRI aims to construct a pan-European distributed infrastructure that boosts research and development in the field of biotechnology by improving access to the microbial resources present in European public collections, their associated data and expertise.

**Objectives**

One of the MIRRI objectives is to create clusters bringing together the expertise available at different partner and non-partner institutions to respond to concrete demands of the MIRRI stakeholders. These expert clusters will provide solutions in aspects such as regulatory framework (e.g. biosecurity, ABS, IPR), managerial best practices, taxonomy or microbial applications, among others.

**Methods**

To design the content, composition and rules of operation of the clusters, the relevant stakeholders have been consulted (face to face meetings, workshops and surveys). An analysis of the comparable RIs of the ESFRI 'Food and Health' group was performed to bridge the gap between information sharing and facilitating a collaboration landscape.

**Conclusions**

Here, we present the concept of the MIRRI Clusters of expertise as a tool to share and generate knowledge within the MIRRI stakeholder community (culture

collections, policy makers, scientists, bioindustry, etc.) to foster innovation within science, research and development. The authors gratefully acknowledge the contribution of the MIRRI consortium and the consulted persons to this work.

This project has received funding from EU FP7 (grant agreement 312251).

<sup>4</sup>School of Mathematics and Statistics, Newcastle University, Newcastle upon Tyne,  
United Kingdom

**Background**

The bacterial flagellum is a complex organelle requiring the coupling of gene expression to the assembly pathway. In *Escherichia coli* and *Salmonella enterica* serovar Typhimurium the *flhDC* operon encodes the essential FlhD<sub>4</sub>C<sub>2</sub> flagellar-specific master transcriptional regulator. The activity of FlhD<sub>4</sub>C<sub>2</sub> is influenced by many flagellar-specific and global regulatory stimuli. FlhD<sub>4</sub>C<sub>2</sub> activity responds to cellular and environmental factors through regulators including OmpR, RcsB and CRP. Flagellar-specific signals known to influence FlhD<sub>4</sub>C<sub>2</sub> activity are controlled by the action of FlhT and FlhZ. *flhDC* expression is also sensitive to cell growth.

**Objectives**

Our objective in this study was to investigate the impact of growth rate on flagellar formation in *E. coli* and *S. Typhimurium*

**Methods**

Our methods to study our objective included the use of steady-state chemostat cultures. Our measure was flagellar abundance using a functional FlhM-GFP fusion protein. We will show that flagellar abundance correlates with growth rate, where faster growing cells produce more flagella in both species. We will present data showing that the impact of transcriptional, post-transcriptional and flagellar-specific regulation of *flhDC* with respect to the growth rate response of the flagellar system leads to a marked difference in flagellar abundance when the species are compared.

**Conclusions**

Our data suggests that even though both flagellar systems have a high degree of genetic similarity the way *E. coli* and *S. Typhimurium* assimilate signals during flagellar regulation may reflect the lifestyle of these two bacterial species.

**TYPE VI SECRETION IN THE SOIL BACTERIUM PSEUDOMONAS PUTIDA:  
ROLE IN BACTERIAL COMPETITION**

P. Bernal<sup>1</sup>, C. Civantos<sup>2</sup>, A. Filloux<sup>1</sup>, M.A. LLamas<sup>2</sup>

<sup>2</sup>Environmental Protection,  
Estacion Experimental del Zaidin (Spanish National Research Council), Granada,  
Spain

**Background**

Bacterial type VI secretion systems (T6SSs) are recently discovered nanomachines used to inject effectors into prokaryotic or eukaryotic cells. T6SSs are therefore involved in both inter-bacterial competition and bacterial pathogenesis.

**Objectives**

The aim of this work is the analysis of T6SS in the soil bacterium *Pseudomonas putida*. *P. putida* is known for its capacity to colonise the root of crop plants providing growth advantages to the plant and, importantly, protection against plant pathogens. Since T6SS is mainly used by environmental bacteria for interbacterial competition, we analysed whether this secretion system of *P. putida* might be involved in such protection.

**Methods**

- *In silico* analysis of *P. putida* KT2440 genome to identify potential T6SSs
- Competition assays to determine *P. putida* T6SS activity and bacterial targets.
- qRT-PCR and transcriptional fusions to study *P. putida* T6SS expression and regulation

**Conclusions**

*P. putida* contains three putative T6SSs named as H1, H2, and H3. These clusters contain the genes encoding the T6SS conserved core components and some accessory proteins, including regulatory proteins and toxins-immunity pairs. Additional T6SS-related genes are found scattered on the chromosome. At least the H1-T6SS is active and used by *P. putida* to kill other bacteria, including the phytopathogen *Pseudomonas syringae*. Expression of this system is maximal in stationary phase and it is controlled by the global regulators RetS and GacS-GacA, and by two alternative sigma factors, RpoS and RpoN.

## **A PSEUDOMONAS FLUORESCENS TYPE VI SECRETION SYSTEM IS INVOLVED IN ANTIBACTERIAL ACTIVITY**

M. Gallique<sup>1</sup>

<sup>1</sup>Laboratory of Microbiology Signals and Microenvironment, University of Rouen, EVREUX, France

### **Background**

To persist in an ecological niche, bacteria have developed several strategies to enable them to resist in the environment. One of these mechanisms able to struggle with other bacterial species is Type VI Secretion System (T6SS). This allows the bacterium to inject toxins directly into prey' cytoplasm and could cause death. A mucoid environmental strain of *Pseudomonas fluorescens*, MFE01, has antibacterial activity carried by T6SS. MFE01 is not virulent against eukaryotic cell models (amoebas, plant or animal cell models). Currently, genomic analysis reveals only one T6SS core component cluster and three *hcp* genes were found (named *hcp1*, *hcp2* and *hcp3*).

### **Objectives**

Aims of this study are to assign a role to each Hcp protein and to test the potential application of this secretion system to prevent infection by nosocomial strain (like *Pseudomonas aeruginosa*) in burn wound.

### **Methods**

Mutations of *hcp1*, *hcp2* and *hcp3* were performed. Furthermore, T6SS apparatus was also inactivated by *tssE* gene mutagenesis. Competitor activity were established in different conditions: immobilized experiment, swarming or swimming conditions. Hereafter, we will use Hacat keratinocyte model to study the ability of MFE01 to protect against infection by etiologic agents.

### **Conclusions**

MFE01 T6SS plays a crucial role in bacterial competition in ecological niche. Hcp2 was involved in antibacterial activity whereas Hcp1 immobilized prey cell. Hcp1 and Hcp2 proteins had a synergic effect which Hcp1 inhibits prey cell mobility and then Hcp2 can killed it. Presently, no role is attributed to Hcp3.

## **MICRO- AND MACRO-SCALE INSIGHTS ON THE TRANSFORMATION OF SELENITE TO SELENIUM NANOPARTICLES BY MIXED MICROBIAL AGGREGATES**

G. Gonzalez-Gil<sup>1</sup>, P. Lens<sup>1</sup>, P. Saikaly<sup>2</sup>

<sup>1</sup>*Pollution Prevention and Control Core, UNESCO\_IHE, Delft, Netherlands*

<sup>2</sup>*Water Desalination and Reuse Center, King Abdullah University of Science and Technology, Thuwal, Saudi Arabia*

### **Background**

Selenium oxyanions can be reduced by diverse microorganisms resulting in the formation of selenium nanoparticles (SeNP). This process has been mostly investigated using pure bacterial cultures. However, using pure cultures for treatment of wastewater containing selenium oxyanions is not recommended. Anaerobic granular sludge, which consists of aggregates of mixed microbial communities, may also reduce selenium oxyanions and would thus be appropriate for developing treatment systems.

### **Objectives**

The aims were: (i) to investigate which microorganisms prevailed in a granular sludge that was exposed to selenite and reduced this oxyanion to SeNP, (ii) to investigate at the macro- and micro-scale the location of the produced SeNP, and (iii) to identify proteins associated to the SeNP.

### **Methods**

High-throughput pyrosequencing, electron microscopy and proteomic approaches were employed.

### **Conclusions**

A large change in the microbial community occurred when the inoculum granular sludge was exposed to and reduced selenite during a 20 day period. Most abundant microorganisms in the selenite reducing granular sludge were affiliated to *Veillonellaceae* and *Pseudomonadaceae* families. Most of selenium bioreduction occurred in the outer layer of the granular sludge, where most biomass contents are localized. At the micro-scale, electron tomography showed that SeNP were produced inside the cells. A proteomic analysis of extracted SeNP revealed that most of their associated proteins were proteins found in the outer and inner membranes. The used granular sludge readily reduced selenite and the combined results allowed proposing mechanisms for the bacterial synthesis of SeNP in these mixed microbial aggregates.

**YERSINIA PSEUDOTUBERCULOSIS TYPE III SECRETION IS RELIANT UPON AN AUTHENTIC DUAL FUNCTIONAL N-TERMINAL YSCX SECRETOR DOMAIN.**

J. Gurung<sup>1</sup>, A. Amer<sup>1</sup>, S. Chen<sup>2</sup>, M. Francis<sup>3</sup>

<sup>1</sup>*Department of Molecular Biology, Umeå University, Umeå, Sweden*

<sup>2</sup>*Wuhan institute of Virology, Chinese Academy of Sciences, Wuhan, China*

<sup>3</sup>*Umeå University, Department of Molecular Biology, Umeå, Sweden*

**Background**

Various Gram negative bacteria employ a type III secretion system (T3SS) to deliver effector proteins into eukaryotic cells to form mutualistic or pathogenic interactions with their host. A T3SS is comprised of about 25 different proteins many of whose functions still remain obscure. In *Yersinia* Ysc-Yop T3SS, YscX and YscY are two proteins which have not been well characterised. However, a Ysc-Yop T3SS is non-functional in the absence of either *yscX* or *yscY*, suggesting that both YscX and YscY are crucial Ysc-Yop T3SS constituents.

**Objectives**

An attempt to understand the role of YscX and YscY was initially investigated by studying the functional interchangeability between genetically conserved members of the YscX-YscY protein families. It suggested that YscX might be functionally unique to *Yersinia* despite reciprocal binding with YscY family members. Intrigued by the specificity of YscX function, we scrutinized the role of YscX N-terminus in secretion of itself and other T3S proteins.

**Methods**

Site directed mutagenesis and defined domain swapping revealed YscX N-terminus to be a critical aspect of *Yersinia* T3S as it prevented the polymerisation of surface localized YscF needle. This was neither due to a defect in YscX secretion potential nor any observable defect in forming a bipartite interaction with YscY or a tripartite interaction with YscV as measured by standard protein interaction assays.

**Conclusions**

Therefore, the YscX N-terminus must perform dual functions; on the one hand it is a secretion recognition motif and on the other, a non-redundant recognition signal important for the correct assembly of Ysc-Yop T3SS.

## **NEW INSIGHTS ON THE ROLE OF SPAS AUTOCLEAVAGE IN SALMONELLA TYPE III SECRETION SYSTEM**

J. Monjaras Feria<sup>1</sup>, S. Wagner<sup>1</sup>

<sup>1</sup>*Microbiology, Interfaculty Institute of Microbiology and Infection Medicine Tübingen, Tübingen, Germany*

### **Background**

The type III secretion system (T3SS also known as 'injectisome') is organized in three main structures: a multi-ring basal body that houses the export apparatus, a needle, and a translocon in the host cell membrane. To assemble a functional T3SS, specific substrates must be targeted to the apparatus in the correct order. The substrate specificity switch from early to intermediate substrates occurs once the needle has reached its full length.

The Salmonella T3SS export apparatus protein SpaS, is a multifunctional component involved in the switch. It consists of a transmembrane region and a C-terminal cytoplasmic domain that undergoes autocleavage at a conserved NPTH motif.

### **Objectives**

Elucidating the timing of autocleavage and why it is critical for SpaS function.

### **Methods**

In this study we test expression and secretion levels of T3 proteins by immunoblotting and blue-native gel electrophoresis to study the composition of the assembled T3SS. Our data are complemented by injectisome purification and its visualization by electron microscopy.

### **Conclusions**

Studying autocleavage in its physiological context we could demonstrate that the kinetics of SpaS autocleavage are not regulated by injectisome state of assembly or secretion and that the autocleavage mechanism is independent from needle length control. Rather, autocleavage is a fast process occurring before SpaS incorporation into the injectisome base, which is demonstrated by the fact that a functional injectisomes can assemble on pre-expressed fully cleaved SpaS. We also found that autocleavage at the NPTH motif is not a prerequisite for switching since also SpaS cleavage by an endogenous site-specific protease leads to functional switching.

<sup>2</sup>*Electricity and Electronics, Universidad del País Vasco UPV/EHU, Leioa, Spain*

<sup>3</sup>*Applied Physics I, Universidad del País Vasco UPV/EHU, Leioa, Spain*

**Background**

Magnetotactic bacteria are motile prokaryotes with the ability to swim along the Earth's geomagnetic field lines due to the presence of intracellular structures called magnetosomes. Magnetosomes are composed of a mineral core of magnetite or greigite surrounded by a 2-4 nm thick lipid bilayer membrane (1). In recent years, the magnetosomes have attracted great attention because of their potential usefulness in biotechnological and biomedical applications (2).

**Objectives**

In this work, we explore different methods to isolate magnetosomes from *Magnetospirillum gryphiswaldense* and check their biocompatibility on eukaryotic cells.

**Methods**

Two mechanic cell lysis procedures are compared based on the amount and quality of the magnetosomes obtained. The isolated magnetosomes were structurally characterized by TEM as cuboctahedral magnetite particles with an average diameter of 45(±3) nm (3). The aggregation behaviour of magnetosomes in solution is followed by Dynamic Light Scattering technique. The Zeta potential was always lower than -30mV indicating moderately stability. Infrared spectroscopy (FT-IR) revealed the presence of poly-β-hydroxybutyrate under some extraction conditions.

The biocompatibility is evaluated *in vitro* in cytotoxicity assays on murine macrophage ANA-1 cell line. Cells are incubated with 30 pg of magnetite per cell and viability is measured using flow cytometer by annexin-propidium staining. Magnetosomes labeled with fluorescein isothiocyanate are used to track the location of the internalized particles in the cells.

**Conclusions**

No evident signs of cytotoxicity were found after 48 hour of incubation.

**DETERMINATION OF VIRULENCE OF FOOD-BORNE SALMONELLA  
SEROTYPES BY USING CAENORHABDITIS ELEGANS AS A MODEL SYSTEM**

D. Aksoy<sup>1</sup>, E. Şen<sup>1</sup>

<sup>1</sup>Biology Department, Trakya University Faculty of Science, Edirne, Turkey

**Background**

Salmonellosis caused by *S. enterica* is an important food-borne disease worldwide and pathogenicity and antibiotic resistance of these bacteria is an important health concern. *C. elegans* is a current nematode model to test pathogenicity of *Salmonella*.

**Objectives**

We determined pathogenicity, antibiotic resistance, serotypes and plasmid profiles of 32 non-typhoidal food-borne *Salmonella* isolates and searched for a correlation between these characteristics among the isolates.

**Methods**

Pathogenicity of isolates was tested in *C. elegans* model. Nematodes (20/group) were fed with *Salmonella* isolates grown on NGM agar (0.6 at OD600). The time required for 50% of nematodes in each group to die (TD50) was calculated. *S. Typhimurium* ATCC14028 and *E. coli* OP50 were used as positive and negative controls, respectively. Plasmids were isolated by Kado-Liu method and examined by agarose gel electrophoresis (0.7%). Serotyping of isolates was done by slide agglutination test and their antibiotic resistance was investigated by disc diffusion method.

**Conclusions**

26 of *Salmonella* isolates belonged to Infantis, 4 to Enteritidis, 1 to Kentucky and 1 to Telaviv serotypes. 6 isolates harboured 1-3 plasmids ranging from 1.2 to 35.8 kb. TD50 values were 4.2±0.5 days for *S. Typhimurium* ATCC 14028 fed, 8.0±0.02 days for *E. coli* OP50 fed, and between 3.5-7.2 days for food-borne *Salmonella* fed nematodes. The significance of differences in TD50 values were tested by t test (p<0.05). 22 of isolates were pathogenic in *C. elegans*; 20 of these isolates were multi-drug resistant, 2 were ciprofloxacin resistant and 21 were nalidixic acid resistant. Multi-drug resistant isolates identified as pathogens in nematodes may pose serious health risk for consumers.

**Bacterial pathogenicity**

## **LECTIN PRODUCTION BY ACINETOBACTER BAUMANNII CLINICAL AND ENVIRONMENTAL ISOLATES**

V. Aleksic<sup>1</sup>, A. Petrovic<sup>1</sup>, M. Petrusic<sup>1</sup>, M. Eper<sup>1</sup>, N. Stankovic-Nedeljkovic<sup>2</sup>,  
P. Knezevic<sup>1</sup>

<sup>1</sup>Department of biology and ecology, Faculty of Sciences-University of Novi Sad,  
Novi Sad, Serbia

<sup>2</sup>Hygienic and Epidemiological Service, Health Center "Aleksinac", Aleksinac, Serbia

### **Background**

*Acinetobacter baumannii* is an emerging opportunistic pathogen which cause severe infections in immunocompromised patients and exhibit resistance to many conventional antibiotics. Factors responsible for *A. baumannii* pathogenesis are numerous; some of them are biofilm formation and hemagglutination, which are dependent on lectin production.

### **Objectives**

The aims were to determine the lectin production ability of the *A. baumannii*, to determine the lectin specificity to different blood types, and to semi-quantify lectin produced by *A. baumannii*.

### **Methods**

The study was carried out with 3 reference strains (ATCC BAA-747, ATCC 19606, NCTC 13423), 8 environmental and 20 MDR *A. baumannii* wound isolates. Lectin production screening was performed using the hemagglutination assay. The supernatant of overnight cultures were examined using 3 % erythrocyte suspension of different blood types (O Rh+, A Rh+ i B Rh+) and results were recorded after 30 min. The semiquantitative determination of lectin production was examined by *ex vivo* modified hemagglutination assay with erythrocyte of A blood type in microplates using two-fold culture supernatant dilutions (from 1/2 to 1/2048).

### **Conclusions**

All examined isolates were able to produce lectins *in vitro* and expressed hemagglutination activity to all examined blood types. The semiquantitative method showed that titer is in a range from 1/4 to 1/64. The clinical strains produced lectins in slightly higher amount compared to the environmental isolates, but without significant statistical difference ( $P>0.05$ ). The results indicate that lectin production can be a new target for development of novel anti-*Acinetobacter* agents.

**MOLECULAR CHARACTERIZATION OF KLEBSIELLA OXYTOCA STRAINS  
ISOLATED FROM PATIENTS WITH ANTIBIOTIC-ASSOCIATED DIARRHEA**

*M. Alikhani<sup>1</sup>, F. Shahcheragh<sup>2</sup>, S. Khodaparast<sup>1</sup>, A. Mozaffari Nejad<sup>1</sup>, S. Mousavi<sup>2</sup>*

<sup>1</sup>*Microbiology, Hamadan University of Medical Sciences, Hamadan, Iran*

<sup>2</sup>*Microbiology, Pasteur Institute of Iran, Tehran, Iran*

**Background**

The main complication of colitis would be seen after antibiotic treatment by  $\beta$  lactams, quinolone and aminoglycosides antibiotics. Recently, *Klebsiella oxytoca* has been known to cause this type of diarrhea.

**Objectives**

Investigating the prevalence and characterizations of *K. oxytoca* isolated from patients with antibiotic associated diarrhea. *K. oxytoca* isolates were also tested for cytotoxin production.

**Methods**

This study was carried out from May 2011 to Dec 2013. Fecal samples were collected from hospitalized patients who received antibiotics. Initial cultivation was performed on specific media. Clinical isolates were confirmed by PCR using the specific *K. oxytoca* polygalacturonase (*pehX*) gene. The double disk diffusion test was used to detect ESBLs producing strains. Tracking ESBLs encoding genes were performed by PCR. The bacteria's cytotoxin production was conducted using cell culture on Hep2 cell lines.

**Conclusions**

Five (12%) isolates had cytotoxin activity less than 30%, 12 (30%) strains had moderate cytotoxin activity between 30 and 60% and 23 (58%) strain had cytotoxin activity equal to/or greater than 60%. The cytotoxin producing *K. oxytoca* can be described as one of the causes of antibiotic induced colitis. Drug discontinuation and creating opportunities for the establishment of intestinal normal flora or appropriate medication after antibiogram would perform better chance earlier in patients with hemorrhagic colitis caused by antibiotics.

**DESIGN AND PRODUCTION OF RECOMBINANT PROTEINS OMP P2, OMP P5 AND D15 OF HAEMOPHILUS PARASUIS AND THE STUDY OF THEIR IMMUNITY IN RABBITS**

Á. Álvarez Estrada<sup>1</sup>, S. Martínez Martínez<sup>1</sup>, E.F. Rodríguez Ferri<sup>1</sup>, S. Yubero<sup>1</sup>, R. Frandoloso<sup>1</sup>, C.B. Gutierrez Martín<sup>1</sup>

<sup>1</sup>Animal Health, University of León, Leon, Spain

**Background**

*Haemophilus parasuis* is the etiological agent of porcine Glässer's disease.

**Objectives**

Based on previous studies, three recombinant outer membrane proteins of *H. parasuis* serovar 5 (P2, P5 and D15) were designed and produced for studying their immunogenicity and potential use as vaccine antigens.

**Methods**

Each gene was amplified and cloned into a pBAD/TOPO vector, this plasmid being enable to express each protein with a tag of histidines for facilitating the subsequent purification. *Escherichia coli* was transformed with the vector and then, it was cultured with arabinose to induce protein expression. As the three proteins were expressed at insoluble fraction, it was necessary to develop a denaturation process using urea, in order to solubilize and refold them. Refolding was performed at the same time as purification by means of immobilized nickel-histidine affinity chromatography. Each of these proteins was retained in the stationary phase and washed with buffers containing decreasing urea concentrations until removing totally urea; the proteins were then eluted with imidazole. Rabbits were used to evaluate the capacity of these proteins to induce a humoral response before testing them in Glässer's disease natural host. Groups of animals were immunized thrice with each of these proteins, and blood was collected after each inoculation. Sera were used to perform indirect ELISAs, in which purified proteins were used as antigen for coating plates.

**Conclusions**

An increasing in antibody titres with seroconversion can be found after immunizations for recombinant P2, P5 and D15 proteins.

**SIDEROPHORE RECEPTOR GENES AS PATHOGENIC MECHANISM IN ADHERENT-INVASIVE ESCHERICHIA COLI STRAINS ISOLATED FROM BIOPSIES OF CHILEAN CROHN'S DISEASE PATIENTS.**

D. Araya<sup>1</sup>, M. De La Fuente<sup>2</sup>, F. Del Canto<sup>1</sup>, M. Hermoso<sup>2</sup>, R. Vidal<sup>1</sup>

<sup>1</sup>Microbiología y Micología, Universidad de Chile, Santiago, Chile

<sup>2</sup>Inmunología, Universidad de Chile, Santiago, Chile

**Background**

Crohn's disease (CD) is a chronic gastrointestinal inflammatory disease. Adherent invasive *Escherichia coli* (AIEC) strains, which have the capacity to attach and invade intestinal epithelial cells, and also survive within macrophages; have been associated with CD.

**Objectives**

To identify immunogenic proteins in the outer membrane of AIEC isolates obtained from Chilean patients with CD, and determine their role in pathogenicity.

**Methods**

AIECs were isolated from biopsies of Chilean patients with CD. AIEC outer membrane proteins (OMPs) were obtained from cultures grown at 20 °C and 37 °C, and separated by SDS-PAGE. Immunogenic proteins were identified by immunoblot using sera from patients with CD and MALDI-TOF/TOF. Genes coding identified proteins were knocked out and mutant strains were characterized according to: 1) Capacity to adhere and invade intestinal cells, and to survive within macrophages. 2) Differential expression of outer membrane proteins by (2D SDS-PAGE and MALDI-TOF/TOF. 3) Capacity to stimulate production of inflammatory cytokines.

**Conclusions**

Siderophore receptors IutA and ChuA were identified as immunogenic OMPs. No effect in adherence and invasion capacity was observed after knocking out their genes, however, mutant strains did not survive within macrophages. Additionally, mutation altered the outer membrane profile by apparently affecting expression of virulence-associated proteins. A decrease in IL-1, IL-2, IL-12, IL-4 and IFN-gamma levels was detected in supernatants of macrophages infected with the mutant, while TNF- alpha level did not change. Therefore, IutA and ChuA would be required for AIEC intracellular survival in the host, in order to capture iron and express virulence factors. Finally mutating these receptors the strain becomes unstable and avirulent bacteria, which can not survive oxidative stress because other virulence genes are repressed by iron deficiency.

### **Background**

*Klebsiella pneumoniae* (*K. pneumoniae*) is one of the main pathogens in nosocomial infections. Type 3 pilus (T3P) is a virulence factor required for biofilm formation and adherence to epithelial cells. Three promoters control the expression of T3P: *mrkA* (codes for the pilin) *mrkHI* (code for two activator proteins) and *mrkJ* (a repressor protein). H-NS nucleoid protein structures the bacterial genome, mainly Gamma-proteobacteria. Hypermucoviscosity that is attributed to the capsule formation, is a hallmark of pathogenic strains. No reports have been described for the role of H-NS protein in regulating T3P and capsule in *K. pneumoniae*.

### **Objectives**

1. Determine the role of H-NS protein in transcription of T3P.
2. Analyze both the biofilm and capsule formation in the absence of H-NS.

### **Methods**

Transcriptional expression of *mrkA*, *mrkH*, *mrkI* and *mrkJ* genes was carried out by qRT-PCR. Using EMSA, promoter regions (PCR) of *mrkA*, *mrkJ* and *mrkHI* were incubated with purified H-NS protein and DNA-proteins complexes were observed. Biofilm formation was quantified by the method of 96-wells polystyrene microplates. The abundance of capsule was determined by measuring spectrophotometrically the supernatants of bacterial cultures at exponential phase.

### **Conclusions**

*K. pneumoniae hns* mutant affected the growth at exponential phase and resulted in a hypermucoviscosity phenotype. The absence of H-NS affected the biofilm formation and differentially regulated the *mrk* promoters: derepressed and repressed to *mrkHI*-*mrkJ* and *mrkA*, respectively. H-NS directly bound to the three promoters of T3P. The H-NS protein is a crucial regulator of the main virulence determinants of *K. pneumoniae*.

**EXOGENOUS SUPPLEMENTATION WITH BRANCHED-CHAIN AMINO ACID PROMOTES AEROBIC GROWTH OF SALMONELLA TYPHIMURIUM UNDER NITROSATIVE STRESS CONDITIONS**

Y.M. Park<sup>1</sup>, I. BANG<sup>1</sup>

<sup>1</sup>Microbiology and Immunology, Chosun University School of Dentistry, Gwangju, Korea

**Background**

An intracellular pathogen *Salmonella enterica* serovar Typhimurium can detoxify cytotoxic nitric oxide (NO) produced in phagocytes of host animals by their metabolism depending largely on the flavohemoglobin Hmp. In *hmp* mutant *S. Typhimurium*, NO causes deficiency in amino acids including branched-chain amino acids (BCAA). In the BCAA biosynthetic pathway, iron-sulfur cluster-containing enzymes dihydroxyacid dehydratase (IlvD) and isopropylmalate isomerase (LeuCD) have been implicated to be targets of NO, suggesting the importance of BCAA metabolism in the NO-induced amino acid auxotrophy.

**Objectives**

This study aimed to determine the effect of BCAA supplementation on *Salmonella* resistance to NO under different oxygen conditions, and to test physiological roles of IlvD and LeuCD in the intramacrophage survival of *Salmonella* in the presence or absence of BCAA supplementation.

**Methods**

Gene mutations deficient in *ilvD* and *leuCD* were constructed in *S. Typhimurium*. With mutant *S. Typhimurium* having combinations of these gene mutations and *hmp* mutation, we measured the effect of BCAA on the susceptibility to nitrosative stress, the NO consumption rate, and the intramacrophage growth.

**Conclusions**

Under nitrosative stress conditions, BCAA supplementation restored the growth of *hmp* mutant and mutants further lacking IlvD and LeuCD in aerobic and semiaerobic cultures, but not in anaerobic cultures. Intracellular survival of *ilvD* and *leuCD* mutants in macrophages was also promoted by BCAA supplementation. Results suggest that the NO-induced BCAA auxotrophy of pathogenic bacteria due to inactivation of iron-sulfur enzymes in the BCAA biosynthetic pathway could be rescued by bacterial taking up exogenous BCAA available in oxic environments of host animals.

**PASTEURELLA MULTOCIDA - A NOVEL PARADIGM FOR BACTERIAL INVOLVEMENT IN CANCER**

A. Banu<sup>1</sup>, A.J. Lax<sup>1</sup>, A.E. Grigoriadis<sup>2</sup>

<sup>1</sup>Microbiology, King's College London, London, United Kingdom

<sup>2</sup>Craniofacial Development and Stem Cell Biology, King's College London, London, United Kingdom

**Background**

*Pasteurella multocida* toxin (PMT) is mitogenic for many cell lines. It acts via modification of three of the four families of heterotrimeric G-proteins which are- G<sub>q/11</sub>, G<sub>12/13</sub> and G<sub>i</sub>. PMT has been shown to induce anchorage independent cell growth, enhance anti-apoptotic proteins, increase  $\beta$ -catenin signalling in a differentiating adipocyte system, and up-regulate JAK/STAT and MAPK signalling pathway, all of which are implicated in various cancers. These different effects of PMT suggest it may have a carcinogenic potential.

**Objectives**

Here we are studying PMT as a potential carcinogen by chronically treating cells *in vitro* with PMT to analyse its involvement in cell transformation.

**Methods**

The following end points are being monitored to assess the carcinogenic potential of PMT: cell proliferation, stress fibre formation, cellular morphology, levels of normal G-proteins, levels of PMT-modified G-proteins, and anchorage independent growth. Results achieved so far show that PMT-treated cells have an increased cell number, show morphological changes, and differences in protein levels compared to the untreated cells.

**Conclusions**

Together the data suggests that prolonged exposure to G-proteins modified by chronic treatment with PMT can set cells along a transformation pathway.

**SINC, A TYPE III SECRETED EFFECTOR OF CHLAMYDIA PSITTACI, TARGETS EMERIN AND THE INNER NUCLEAR MEMBRANE OF INFECTED CELLS AND UNINFECTED NEIGHBORS**

S.A. Mojica<sup>1</sup>, K.M. Hovis<sup>1</sup>, M.B. Frieman<sup>2</sup>, B.A.O. Tran<sup>3</sup>, R. Hsia<sup>4</sup>, J. Ravel<sup>5</sup>, K.L. Wilson<sup>6</sup>, P. Bavoil<sup>1</sup>

<sup>1</sup>Microbial Pathogenesis, University of Maryland Baltimore, Baltimore, USA

<sup>2</sup>Microbiology and Immunology, University of Maryland Baltimore, Baltimore, USA

<sup>3</sup>Mass Spectrometry Center, University of Maryland Baltimore, Baltimore, USA

<sup>4</sup>Electron Microscopy Core Imaging Facility, University of Maryland Baltimore, Baltimore, USA

<sup>5</sup>Institute for Genome Science, University of Maryland Baltimore, Baltimore, USA

<sup>6</sup>Cell Biology, Johns Hopkins University, Baltimore, USA

**Background**

*Chlamydia* species encode a type III secretion (T3S) system that enables the translocation of effector proteins into the host cell cytosol, where they target host pathways to benefit the pathogen. We have identified SINC, a novel T3S effector of *Chlamydia psittaci*, a highly infectious avian pathogen, and medically significant zoonotic pathogen of humans.

**Objectives**

To identify and characterize the eukaryotic target(s) of SINC.

**Methods**

Immunofluorescence, immunoelectron microscopy, differential digitonin permeabilization, inhibitors of nuclear transport, BioID (in situ biotinylation analysis of effector-BirA-proximal eukaryotic targets, streptavidin affinity purification, mass spectrometry).

**Conclusions**

SINC uniquely targets the nuclear envelope (NE) of *C. psittaci*-infected cells and uninfected neighboring cells. Digitonin-permeabilization studies of infected or SINC-GFP-transfected HeLa cells indicate SINC targets the inner nuclear membrane (INM). SINC localization at the NE was blocked by importazole, confirming SINC import into the nucleus. Candidate partners were identified by proximity to biotin ligase-fused SINC in HeLa cells and mass spectrometry. Several candidates were identified with high confidence including the nucleoporin ELYS, lamin B1 and four INM proteins (emerin, MAN1, LAP1 and LBR), suggesting SINC interacts with host proteins that control nuclear structure, signaling, chromatin organization and gene silencing. GFP-

SINC association with the native LEM-domain protein emerin, a conserved component of nuclear 'lamina' structure, was confirmed by GFP pull-down. We conclude that SINC is a novel bacterial effector with the capability of globally altering nuclear envelope functions in the infected host cell and neighboring uninfected cells. These properties may contribute to the aggressive virulence of *C. psittaci*.

<sup>3</sup>Centre for Immunology and Infectious Disease, Queen Mary University of London, London, United Kingdom

### **Background**

Colorectal cancer (CRC) remains one of the most prevalent cancers in the Western world. However, the factors leading to the development of colon cancer have not been determined, with genetics, diet and other environmental factors all likely to play a role. Mechanisms by which *Bacteroides fragilis* and *Fusobacterium nucleatum* may drive colonic tumour development have been identified. Some *B. fragilis* isolates contain a metalloprotease toxin known as BFT or fragilysin. BFT has been demonstrated to promote colonic hyperplasia in animal models. *F. nucleatum* is of relevance due to the consistent finding across several studies that it is enriched on CRC tumours. Its FadA adhesin can mediate invasion into the cell with a resultant increase in expression of host oncogenes.

### **Objectives**

Advances in next generation sequencing technologies have led to a high resolution of the CRC microbial community. The aim of this study is to use a hypothesis led approach to focus on potential key isolates and genes in the development of colonic tumours.

### **Methods**

We are compiling a comprehensive collection of human colonic tissue from patient cohorts representing different stages of disease. These samples are being analysed using a PCR-based assay to determine the prevalence of selected bacterial taxa and genes. Results show primer specificity, PCR optimization and sensitivity of detection that have been experimentally determined.

### **Conclusions**

Overall this work describes the design and validation of a panel of primers with the intention of analysing a fresh collection of human tissue. Preliminary findings using a collection of pilot samples will be presented.

#### • GENOMIC CHARACTERIZATION OF AVIAN PATHOGENIC AND COMMENSAL CHICKEN *E. COLI* ISOLATES

E. Trost<sup>1</sup>, D. Biran<sup>2</sup>, C. Schouler<sup>3</sup>, E. Oswald<sup>4</sup>, E. Ron<sup>2</sup>, U. Dobrindt<sup>1</sup>

<sup>1</sup>Institute of Hygiene, University of Münster, Münster, Germany

<sup>2</sup>Dept. of Microbiology & Biotechnology, Tel Aviv University, Tel Aviv, Israel

<sup>3</sup>UMR1282 Infectiologie et Santé Publique,  
Institut National de recherche Agronomique, Nouzilly, France

<sup>4</sup>UMR960 INRA-ENVIT Microbiologie, École Nationale Vétérinaire de Toulouse,  
Toulouse, France

### Background

Extraintestinal pathogenic *E. coli* (ExPEC) are a major source of urinary tract infection, newborn meningitis and sepsis in humans. Avian pathogenic *E. coli* (APEC) cause colibacillosis, a complex systemic infection in poultry. Certain human ExPEC and APEC cannot be clearly distinguished based on molecular epidemiology and their virulence-associated genome content. APEC are considered as a reservoir of virulence- and resistance genes for human ExPEC and a zoonotic risk cannot be excluded.

### Objectives

To characterize potential differences between APEC and chicken commensal *E. coli*, we compared the virulence- and antibiotic resistance-associated genome content of commensal *E. coli* isolates from healthy chicken with APEC strains.

### Methods

*E. coli* isolates from tracheal and fecal samples of healthy chicken were collected and subjected to virulence gene and antibiotic resistance profiling. The genomes of 127 commensal and APEC isolates were sequenced.

### Conclusions

The virulence gene content of commensal chicken and APEC isolates was similar. Comprehensive genome comparison of APEC and chicken commensals will extend our knowledge of bacterial traits that could contribute to pathogenesis and antibiotic resistance. Interestingly, animal husbandry has a great impact on the spread of antibiotic resistance determinants among chicken *E. coli* isolates. As APEC have a zoonotic potential and serve as potential gene pool for human ExPEC, the increased presence of antibiotic resistance determinants in *E. coli* from conventionally raised

chicken can facilitate the spread of multiresistant human ExPEC.

**PROPERTIES OF THE DSBA PROTEIN (CLA0559) FROM CAMPYLOBACTER LARI RM2100.**

A.M. Łasica<sup>1</sup>, K.M. Bocian-Ostrzycka<sup>1</sup>, A. Mikołajczuk-Szczyrba<sup>1</sup>, K. Jastrząb<sup>1</sup>,  
E.K. Jagusztyn-Krynicka<sup>1</sup>

<sup>1</sup>Institute of Microbiology Department of Bacterial Genetics,  
University of Warsaw Faculty of Biology, Warsaw, Poland

**Background**

*Campylobacter spp.* are known to be one of a major cause of gastrointestinal illness throughout the world. Most prevalent species responsible for human infections are *C. jejuni* and *C. coli*. Human infections by *Campylobacter lari* are also associated with gastrointestinal diseases but mostly in developing countries. So far, little is known about *C. lari* molecular attributes. CLA0559 protein shows high homology to members of DsbA family. As Dsb enzymes control the formation and rearrangement of disulfide bonds during the folding of extracytoplasmic proteins they play an important role in pathogenesis. *In silico* analysis indicate that *C. lari* Dsb system might be a novel, different from the ones described for those operating in *E. coli* or *C.jejuni* cells.

**Objectives**

*C. lari* CLA0559 mutant remains motile but becomes sensitive to DTT. *E. coli* complementation tests (cadmium resistance, motility test and alkaline phosphatase assay) clearly showed that CLA0559 substitutes for EcDsbA activity and acts in cooperation with EcDsbB. CLA0559 functions *in vitro* as an oxidase. It was proven by *in vitro* RNase activity assay. CLA0559 doesn't cooperate with CIDsb1/Dsb12, homologs of DsbB).

**Methods**

All genetic manipulations were performed using standard molecular biology procedures. For complementation purposes in *E. coli* cells *CldsbA* was expressed from low copy vector. *In vitro* tests were performed with CIDsbA purified from *E. coli* using affinity and size exclusion chromatography

**Conclusions**

Our results showed that *cla0559* gene encodes for CIDsbA protein functioning in an oxidizing pathway in *C. lari* cells. Its redox partner still remains unknown.

**FEMS-2371**

**IN VITRO PROPERTIES OF THE TRUNCATED FORM OF HELICOBACTER  
PYLORI HP0231 PROTEIN.**

K.M. Bocian-Ostrzycka<sup>1</sup>, A.M. Łasica<sup>1</sup>, A.M. Dobosz<sup>1</sup>, K. Drabik<sup>1</sup>, E.K. Jagusztyn-Krynicka<sup>1</sup>

<sup>1</sup>*Institute of Microbiology Department of Bacterial Genetics,  
University of Warsaw Faculty of Biology, Warsaw, Poland*

**Background**

Dsb proteins control the formation and rearrangement of disulfide bonds during the folding of membrane and exported proteins. The mechanism of disulfide bond formation in microorganisms is extremely diverse. The *H. pylori* Dsb system seems to be novel and different from the Dsb system in *E. coli*. Dsb system plays an important role in *H. pylori* pathogenesis as *H. pylori* mutant impaired in disulfide bond formation revealed greatly reduced ability to colonize mice gastric mucosa.

**Objectives**

Our recent work led to the characterization of the HP0231 functioning mainly in an oxidizing pathway in *H. pylori* cells. It is intriguing that HP0231 acts as periplasmic oxidase, as EcDsbA, despite its structural resemblance to EcDsbG. Additionally HP0231 acts as chaperone and is involved in the cytochrome c biogenesis. To assess relations between HP0231 structure and its oxidizing activity we tested biochemical activities of the truncated form of HP0231 (HP0231m) containing only catalytic domain.

**Methods**

All genetic manipulations was performed using standard molecular biology procedures. Correctness of the obtained constructs were verified by sequencing. HP0231m was overexpressed in *E. coli* Rosetta strain and purified using NGC™ Medium-Pressure Chromatography (Bio-Rad). Purified protein was used to perform insulin reduction assay, chaperone activity assay and izomerization/oxidation RNase activity test.

**Conclusions**

Our results show that HP0231m mutated protein possess chaperone activity slightly higher than native HP0231 form and at the same time it lost ability to reduce insulin. It displays the same level of oxidation activity as HP0231 and similarly to native HP0231 does not have izomerization activity.

**NOD1+32656 T>GG FUNCTIONAL POLYMORPHISM AFFECTS SUSCEPTIBILITY TO CHLAMYDIA TRACHOMATIS (CT) INFECTION AND RISK OF TUBAL FACTOR INFERTILITY IN WOMEN**

*I. Brankovic<sup>1</sup>, E. van Ess<sup>2</sup>, M.P. Noz<sup>2</sup>, W.J. Wiericx<sup>2</sup>, J. Spaargaren<sup>2</sup>, J.A. Land<sup>3</sup>, S. Ouburg<sup>2</sup>, S.A. Morré<sup>2</sup>*

<sup>1</sup>*Genetics & Cell Biology, Maastricht University, Maastricht, Netherlands*

<sup>2</sup>*Medical Microbiology and Infection Control, VU Medical Center, Amsterdam, Netherlands*

<sup>3</sup>*Obstetrics and Gynaecology, UMC Groningen, Groningen, Netherlands*

**Background**

Genital *CT* infections cause tubal factor infertility (TFI) in some women. Bacterial motif recognition by intracellular pattern-recognition receptors NOD1 and NOD2 can trigger immune response. Whether their functional polymorphisms impact *CT* infection has not been researched.

**Objectives**

Our objective was to test the effects *NOD1*+32656 T>GG and *NOD2* 1007fs on susceptibility and severity of *CT* infection in Dutch Caucasian women.

**Methods**

*Susceptibility cohort:* We selected 737 women visiting the Amsterdam STD outpatient clinic. Questionnaires were collected in regards to urogenital complaints.

*Severity cohort:* 490 Dutch Caucasian female patients visiting the UMC Groningen Fertility clinic were selected. Laparoscopy was used to grade the tubal pathology status as TFI grade 0-4. Controls were TFI grade 0 as assessed by either laparoscopy or hysterosalpingography (HSG).

**Conclusions**

The *NOD1* +32656 GG insertion appears protective against *CT* infection, but predisposes to TFI and a higher occurrence of symptoms in women with a past *CT* infection. The GG variant might be enhancing successful clearing while acting deleterious in the upper genital tract, causing tubal pathology.

**GENOTYPIC AND PHENOTYPIC CHARACTERIZATION OF ATYPICAL ENTEROPATHOGENIC ESCHERICHIA COLI (AEPEC) AND ENTEROHEMORRHAGIC E. COLI (EHEC) ISOLATED FROM OVINE IN BRAZIL**

*C. Bruschi<sup>1</sup>, F. Martins<sup>2</sup>, J. Pelayo<sup>2</sup>*

<sup>1</sup>CBQF, Universidade Catolica Portuguesa, Porto, Portugal

<sup>2</sup>Bacteriology, Universidade Estadual de Londrina, Londrina, Brazil

**Background**

Atypical Enteropathogenic Escherichia coli (aEPEC) and Enterohemorrhagic E. coli (EHEC) are human pathogens that causes attaching and effacing lesions (A/E) in the intestinal mucosa. EHEC differs from aEPEC because it carries stx genes.

**Objectives**

Characterizing genotypic and phenotypic samples of aEPEC and EHEC.

**Methods**

E. coli was isolated from 130 healthy sheep and characterized by PCR technique as aEPEC (eae+/bfpA/stx-) and EHEC (eae+/stx+). 25 samples of aEPEC and 14 samples of EHEC were analyzed by PCR for presence of ehx, tirY-P (Tir phosphorylated), tirS (no phosphorylated), tccp e tccp2. PCR-triplex was used for phylogenetic classification with chuA, vjaA genes and fragments of TspE4.C2. Samples were also tested for sorbitol fermentation (SOR), enzymatic activity of  $\beta$ -D-glucuronidase (GUD), hemolysins production and HEp-2 cell adhesion.

**Conclusions**

The stx gene subtypes analysis by PCR and cytotoxic effect in Vero cells were realized only in EHEC. The ehx, tirY-P, tirS e tccp2 genes frequency was 40, 60, 16 and 16% in aEPEC and 78, 64, 7 and 28% in EHEC. The tccp gene was present only in aEPEC and only two aEPEC samples were SOR-/GUD+, being the another samples characterized as SOR+/GUD+. Enterohemolysin expression was analyzed in 32% of aEPEC and 66% of EHEC. A diversity patterns adhesion were observed. For the phylogeny, both patotypes were classified as belonging to B1 group. A 100% of EHEC samples presented cytotoxic effect in Vero cells, eight (57%) presented stx1c and seven (60%) stx2d. We concluded that aEPEC and EHEC, isolated from ovine, are two heterogenic groups of bacteria.

## **DOMINANT GENOTYPE OF STAPHYLOCOCCUS AUREUS IN A WELFARE CENTER**

A. Hamdan<sup>1</sup>, R. Hernández<sup>1</sup>, S. González<sup>1</sup>, J. Bustos<sup>1</sup>

<sup>1</sup>Atención a la Salud, Universidad Autónoma Metropolitana - Xochimilco, Mexico City, Mexico

### **Background**

*Staphylococcus aureus* is associated with various diseases both in hospitals and in the community. The MRSA strains had manifested primarily in hospitals, but in recent years have appeared in community outbreaks in healthy people, so is called MRSA strains community-acquired (CA-MRSA), and now is important its detection.

### **Objectives**

Identify MRSA strains in vulnerable adults admitted to a Welfare Center

### **Methods**

Pharyngeal, nose and hands swabs were taken, of 100 volunteers in two samples of 50 people each; one in November 2012 and another in May 2014. The presence of *S. aureus* was determined by microbiological methods and biochemical tests. MIC for oxacillin was performed. Detection of genes for resistance to methicillin, *mecA* and Panton-Valentine Leukocidin, *lukS-PV* / *lukF-PV*, was made by PCR. The strains were typed by *spa*-typing and the clonal determination was performed by PFGE.

### **Conclusions**

44 strains of *S. aureus* were isolated: 15 in throat, 13 in nose, and in 16 hands. Only two strains were resistant to methicillin. The dendrogram obtained from PFGE banding pattern shows that almost all strains are identical, which was corroborated by the *spa*-type where 83% of the strains tested showed the same *spa*-type t003.

One dominant genotype of *S. aureus* in the population studied was found: *spa*-type t003. The MRSA clone of this type is dominant in Europe, but was not reported in Mexico in addition the type found here is methicillin-susceptible (MSSA). It could be a health problem in this community center.

**DETECTION OF COMMUNITY-ACQUIRED METHICILLIN-RESISTANT STAPHYLOCOCCUS SPP IN ICU AND IN AREA HOSPITAL.**

A. Hamdan<sup>1</sup>, S. Robles<sup>1</sup>, M. Soriano<sup>1</sup>, S. González<sup>1</sup>, J. Bustos<sup>1</sup>

<sup>1</sup>Atención a la Salud, Universidad Autónoma Metropolitana - Xochimilco, Mexico City, Mexico

**Background**

Nosocomial infections are an important cause of morbidity and mortality worldwide. At present, *Staphylococcus aureus* and *Staphylococcus epidermidis* are important etiologic agents of hospital infections. *S. aureus* is common in surgical areas of adult intensive care (ICU), sepsis being the most common process involved. Currently strains of community-acquired MRSA (CA-MRSA) have entered in the hospitals.

**Objectives**

The aim of this study was to detect the strains of community-acquired methicillin-resistant *Staphylococcus* in a General Hospital

**Methods**

Swabs of oral and nasal cavity of 52 patients, both male and female with different pathologies were taken, aged between 28 and 72 years, 14 patients were in the ICU and 38 the hospitalization area. The presence of *S. epidermidis* or *S. aureus* was determined by microbiological methods. MIC for oxacillin was measured. The presence of the *mecA* gene, the Panton-Valentine leukocidin gene, and the arginine catabolic mobile (ACME) gene, were detected by PCR. The strains were typed by *spa*-type.

**Conclusions**

We found that 100% of the samples analyzed in the area of hospitalization were strains of *S. aureus*, of which 37% were resistant to methicillin (MRSA). While 93% of the strains tested in ICU were *S. epidermidis*, and 31% of these were methicillin resistant (MRSE). All methicillin-resistant strains showed the presence of the *mecA* gene. One CA-MRSA strain and two CA-MRSE strains were found.

We detected the presence of community-acquired methicillin-resistant *Staphylococcus* in the hospital analyzed, so it is important to conduct periodic sampling to prevent outbreaks caused by this pathogen.

**FEMS-2256**

**Bacterial pathogenicity**

**DETECTION OF COMMUNITY-ACQUIRED METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS IN A NURSERY**

A. Hamdan<sup>1</sup>, S. González<sup>1</sup>, J. Bustos<sup>1</sup>

<sup>1</sup>Atención a la Salud, Universidad Autónoma Metropolitana - Xochimilco, Mexico City, Mexico

**Background**

*Staphylococcus aureus* is a microorganism of great medical importance. For many years it has been recognized as one of the major pathogens for humans. Infections with methicillin-resistant *S. aureus* (MRSA), are usually acquired in hospitals (strains HA-MRSA). However, in the late 90's, MRSA strains emerged in healthy adults and children in communities. These strains cause infections in the community. The prevalence of these infections has increased significantly in recent years. Strains of *S. aureus* that cause these infections are called strains MRSA community-acquired (CA-MRSA).

**Objectives**

The aim of this work was to make the identification and molecular characterization of strains of *Staphylococcus aureus* isolated in a daycare of Mexico City.

**Methods**

Throat swabs samples from 87 children, between 2 and 6 years old were taken. *S. aureus* was identified by microbiological methods. The *mecA* and Panton-Valentine leukocidin (PVL) genes were detected by PCR. The *SCCmec* type and *spa*-type were determined.

**Conclusions**

25% of the population had *S. aureus* in the throat. From the strains isolated, we found that 22% (five strains) were MRSA, of which only one present the *mecA* gene, the gene of PVL and *SCCmec* type IV, therefore we found a CA-MRSA strain. The results show there may be strains CA-MRSA in healthy carriers in Mexico City, so strains CA-MRSA are present circulating in the community.

**FEMS-2312**

**Bacterial pathogenicity**

**PRESENCE OF COMMUNITY-ACQUIRED METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS IN AN ORPHANAGE**

A. Hamdan<sup>1</sup>, S. González<sup>1</sup>, J. Bustos<sup>1</sup>

<sup>1</sup>Atención a la Salud, Universidad Autónoma Metropolitana - Xochimilco, Mexico City, Mexico

**Background**

*Staphylococcus aureus* is a pathogenic bacterium that is associated with various diseases both in hospitals and in the community. Between 20% and 35% of the adult population are carriers of this microorganism in the nasal vestibule, but can also be found in the pharynx of people. The MRSA strains had manifested primarily in hospitals, but in recent years have appeared in community outbreaks in healthy children and adults, with no history of hospitalization. These strains were called community-acquired methicillin-resistant *Staphylococcus aureus* (CA-MRSA).

**Objectives**

The objective of this work was to detect the presence of strains CA-MRSA in an orphanage in Mexico City.

**Methods**

Pharyngeal and nasal swabs of 80 people between 3 and 19 years old of both genders were taken. We identified *S. aureus* by microbiological methods. The *mecA* and Panton-Valentine leukocidin (PVL) genes were detected by PCR. The *SCCmec* type and *spa*-type were determined.

**Conclusions**

56% of the population had *S. aureus*; 12.5% only in the pharynx, 17.5% only in the nose and 26% at both sites. We detected only four MRSA strains (5%), one in the pharynx and three in the nose, which presented the *mecA*, the PVL genes, and have the *SCCmec* type IV, so they are CA-MRSA strains. The results show that there are CA-MRSA strains in healthy children and adolescents in an orphanage in Mexico City.

**IDENTIFICATION AND REGULATION OF A NOVEL CITROBACTER RODENTIIUM GUT COLONIZATION FIMBRIAE (GCF)**

G.G. Caballero Flores<sup>1</sup>, M.A. Croxer<sup>2</sup>, V.I. Martínez Santos<sup>1</sup>, B.B. Finlay<sup>2</sup>, J.L. Puente<sup>1</sup>

<sup>1</sup>Departamento de Microbiología Molecular, Instituto de Biotecnología UNAM, Cuernavaca, Mexico

<sup>2</sup>Michael Smith Laboratories, University of British Columbia, Vancouver British Columbia, Canada

**Background**

*Citrobacter rodentium* is a natural mouse bacterial pathogen that has been extensively used as a surrogate model for studying the human pathogens enteropathogenic and enterohemorrhagic *Escherichia coli*. During infection these pathogens employ surface structures called fimbria to adhere and colonize the host intestinal epithelium; however, for *C. rodentium* only a small number of its fimbrial operons have been studied.

**Objectives**

To analyze the regulation and role in colonization of the *C. rodentium* fimbrial operon *gcfFGABCDE*.

**Methods**

The role in colonization of the Gcf fimbriae was evaluated in mouse colonization assays, while the regulation of the *gcf* operon was assessed using transcriptional fusions and western blot. The promoter of *gcf* was identified by *in silico* analysis, primer extension assays and site-directed mutagenesis. Mutant strains and electrophoretic mobility shift assays were used to determine the role of H-NS as a repressor of *gcf* expression.

**Conclusions**

Here we report the characterization of Gcf (Gut colonization fimbriae) as an important *C. rodentium* colonization determinant of the mouse gastrointestinal tract. We demonstrated that the promoter of the *gcf* fimbrial operon is highly repressed under several *in vitro* growth conditions by H-NS1, one of the five H-NS paralogs encoded in the *C. rodentium* genome. H-NS binds to the regulatory region of *gcf*, further supporting its direct role as a repressor. The *gcf* operon possesses novel and interesting features that open future opportunities to expand our knowledge of these

essential bacterial structures during infection. Work supported by grants IN209713 (DGAPA) and 154287 (CONACyT).

**Background**

*Salmonella* Typhimurium infects a wide range of animal hosts, and generally causes a self-limiting gastroenteritis in humans. However, some variants of this serovar, sequence-type ST313, have been associated with an emergent invasive *Salmonella* disease in sub-Saharan Africa, which usually affects susceptible HIV<sup>+</sup> or malarial individuals. A genomic comparison between an ST313 isolate, D23580, and the well-characterized 4/74 strain (sequence-type ST19) shows that both strains share 96% coding genes. Genetic differences include 1000 SNPs, D23580-specific prophages and the presence of pseudogenes.

**Objectives**

We tested the hypothesis that the two strains had different pathogenic mechanisms that are reflected by altered gene expression patterns and gene fitness in environmental conditions that reflect the infectious process.

**Methods**

RNA-seq-based transcriptomic data were obtained for strains 4/74 [1] and D23580 grown under seventeen infection-relevant *in vitro* conditions. Transcriptomic data were validated with a proteomic approach. In addition, a transposon library was generated in the D23580 strain and sequenced after passaging in different media.

**Conclusions**

Comparative transcriptomics between the two strains revealed that the proportion of differentially-expressed genes varied between 1% to 9% of all genes in various stress conditions. Proteomics for the early stationary phase condition confirmed 60% and 54% of the transcriptomic data in 4/74 and D23580, respectively. We are currently analysing the D23580 transposon library data. The differences observed in the expression and fitness of virulence-associated genes under specific environmental conditions may reflect altered regulatory mechanisms of these *Salmonella* strains.

## **ADHERENCE PROFILE OF ATYPICAL ENTEROPATHOGENIC ESCHERICHIA COLI (AEPEC) STRAINS ISOLATED FROM DOGS IN BRAZIL**

A.M.F. Cerqueira<sup>1</sup>, A.V. Barbosa<sup>2</sup>, J.R.C. Andrade<sup>2</sup>

<sup>1</sup>*Microbiologia e Parasitologia, Universidade Federal Fluminense, Niterói, Brazil*

<sup>2</sup>*Microbiologia e Parasitologia, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil*

### **Background**

Atypical Enteropathogenic *E. coli* (aEPEC) is a human pathotype implicated in endemic infantile diarrhea. aEPEC with an identical virulence gene profile has been isolated from several animals including dogs, suggesting a zoonotic behavior. Adherence to host enterocytes is a key step of aEPEC virulence, being mediated through the expression of LEE locus genes, leading to formation of attaching-effacing (A/E) lesions. However, similar to LEE-positive Shiga Toxin-producing *E. coli* (STEC), aEPEC may contain distinct non LEE-associated effectors molecules and adhesins.

### **Objectives**

Investigate the adhesion profile of aEPEC strains through search of non LEE-associated virulence markers and interaction assays with epithelial cells.

### **Methods**

We analyzed by PCR the distribution of several virulence genes, including 16 *nle* genes, among aEPEC strains isolated from children (n=5) and dogs (n=5). Adherence phenotypes were determined through *in vitro* assays with HEp-2, Caco-2 and T84 cells.

### **Conclusions**

The occurrence of virulence genes was: *ecpA* (100%), *fimH* (80%), *lpfA* (60%), *hcpA* (50%), *toxB* (30%), *iha* (10%). Fifteen *nle* genes were detected in all strains with different combinations. aEPEC of O157:H7 and O4:H16 serotypes carried the *nleB* and *nleE* genes, both located in PAI-122, an important pathogenicity island of STEC O157:H7. All strains showed a localized-like adherence phenotype (LLA) in HEp-2, Caco-2 and T84 cells. Although aEPEC strains are a very heterogeneous group, these findings show a similar virulence profile between human and canine isolates belonging to the same serotype, suggesting an important role for dogs in the maintenance of the virulence gene pool of aEPEC.

**PRESENCE OF L-ASPARAGINASE II (ANSB) IN OUTER MEMBRANE PROTEIN EXTRACTS OF SHIGA TOXIN-PRODUCING ESCHERICHIA COLI (STEC) AND ITS ROLE IN PATHOGENICITY.**

*N. Chamorro Veloso<sup>1</sup>, M. López Nitsche<sup>2</sup>, D. Montero Forero<sup>1</sup>, M. Pardo Córdova<sup>1</sup>, A. Torres Muñoz<sup>1</sup>, R. Vidal Alvarez<sup>1</sup>*

<sup>1</sup>MICROBIOLOGY, Facultad de Medicina Universidad de Chile, Santiago, Chile

<sup>2</sup>IMMUNOLOGY, Facultad de Medicina Universidad de Chile, Santiago, Chile

**Background**

L-asparaginase II (AnsB) enzyme of *E. coli*, known for their use in treatment of children with acute lymphoblastic leukemia (ALL), and has been described as a bacterial periplasmic protein. However, we detected its presence in outer membrane proteins (OMP) extracts of different STEC serotypes, by Western blot using sera from STEC infected-patients and diagnosed with HUS. Recent reports using a mouse T cells co-cultured with wild type *S. Typhimurium* strain, showed that AnsB is sufficient to suppress T lymphocyte blastogenesis.

**Objectives**

Determine the AnsB presence in outer membrane protein extract of different STEC serotypes, its secretion and effect on T lymphocyte proliferation

**Methods**

The OMP and soluble proteins fractions were separated by SDS- PAGE 12% and western blot directed to AnsB detection was performed with commercial specific antibody anti-AnsB. A electron microscopy using a secondary antibody labeled with gold particles for visualization by immunogold was done. Peripheral blood mononuclear cells, from healthy individuals were incubated in the absence or presence of STEC O157: H7, O157:H7 $\Delta$ ansB, O157:H7 $\Delta$ ansB/pVB1\_ansB, STEC O113:H21, commensal *E. coli* HS strain and *S. Typhimurium*, as a negative and positive control for AnsB effect, respectively. The suppression of proliferation was measured by flow cytometry. Study protocols for peripheral-blood mononuclear cells were approved by the Institutional Review Board of the Faculty of Medicine, University of Chile.

**Conclusions**

We observed by immunogold that the AnsB enzyme is secreted and some molecules remain associated with the outer membrane in STEC. AnsB expressed in O157: H7 contribute to its pathogenicity by inhibiting T lymphocyte proliferation.

## **INSIGHTS INTO THE AUTOTRANSPORT PROCESS OF TRIMERIC AUTOTRANSPORTER YAD A.**

N. Chauhan<sup>1</sup>, D. Linke<sup>1</sup>

<sup>1</sup>Department of Biosciences, University of Oslo, Oslo, Norway

### **Background**

YadA is a trimeric autotransporter adhesin present in *Yersinia enterocolitica* and *Yersinia pseudotuberculosis*. It has a transmembrane domain which forms a highly stable  $\beta$ -barrel anchoring it to the outer membrane and an N-terminal passenger domain which translocates through the  $\beta$ -barrel forming a coiled-coil stalk followed by a sticky head which mediates attachment of bacteria to host cell ECM components (1). The mechanism by which the N-terminal domain is translocated is still under debate. A relatively flexible region has been found near the C- terminus of the passenger domain known as the ASSA region which has been proposed to act as a hairpin during translocation (2).

### **Objectives**

The idea is to mutate residues in the 'ASSA' region to obtain stalled translocation intermediates. The intermediates will be analyzed with various methods, followed by structural analysis using solid state NMR experiments.

### **Methods**

**Heat stability assays** of the mutants indicated a different tertiary structure as well as less stability compared to wildtype. **Infrared Spectroscopy** indicated loss of  $\alpha$ -helical content of mutant YadA by 33%. **Electron Microscopy** images showed that mutant YadA does not form fibre-like projections on cell surface and cells do not autoaggregate which was proved in **Autoaggregation assays**.

### **Conclusions**

Preliminary results indicate a translocation intermediate which needs to be further analysed by ssNMR.

**FUNCTIONAL GENETIC ANALYSIS OF THE ENVZ-OMPR TWO-COMPONENT SYSTEM IN ENTEROHEMORRHAGIC E. COLI PATHOGENICITY**

S. Wang<sup>1</sup>, C. Chen<sup>2</sup>

<sup>1</sup>*Institute of Basic Medical Sciences, National Cheng Kung University, Tainan, Taiwan*

<sup>2</sup>*Institute of Basic Medical Sciences and Department of Biochemistry and Molecular Biology National Cheng Kung University, National Cheng Kung University, Tainan, Taiwan*

**Background**

Enterohemorrhagic *Escherichia coli* O157:H7 (EHEC) causes severe diarrhea, hemorrhagic colitis, and can also lead to life-threatening diseases like hemolytic uremic syndrome (HUS). Several EHEC virulence factors have been reported and encoded in the virulence plasmid pO157 and the O157 pathogenicity islands (O-Islands), including the locus of enterocyte effacement (LEE) island (148 O-Island encodes the type three secretion system and effector proteins) and the 93 and 45 O-Islands (encode the two Shiga-like toxins).

**Objectives**

In our previous studies, we utilized the model animal *C. elegans* for studying EHEC infection *in vivo*. Using this EHEC-*C. elegans* model to perform an EHEC transposon library screen, we found that mutations in the *ompR* gene confer the virulence-attenuated phenotype of EHEC against *C. elegans* animals. Here, we aimed to test whether the EnvZ-OmpR two-component system can regulate these reported EHEC virulence genes to infect *C. elegans*.

**Methods**

We identified several potential OmpR binding sites in the promoter regions of these EHEC virulence genes through *in silico* analysis. Furthermore, the mRNA transcript levels of these EHEC virulence genes were significantly down regulated in the *ompR* deletion mutant.

**Conclusions**

Taken all together, our current data suggested that OmpR is one of the EHEC virulence master regulators to manipulate the expression of virulence factors during infection *in vivo*.

## **FUNCTIONAL ANALYSIS OF BIOCONTROL BACTERIUM PSEUDOMONAS TAIWANENSIS**

W.J. Chen<sup>1</sup>, Y.L. Yang<sup>1</sup>, T.Y. Kuo<sup>1</sup>, J.R. Liu<sup>2</sup>, M.C. Shih<sup>1</sup>

<sup>1</sup>Agricultural Biotechnology Research Center, Academia Sinica, Taipei, Taiwan

<sup>2</sup>Institute of Biotechnology, National Taiwan University, Taipei, Taiwan

### **Background**

*Pseudomonas taiwanensis* is a broad host range Gram-negative bacterium. Recently, we found that *P. taiwanensis* displayed strong antagonistic activity against rice pathogen *Xanthomonas oryzae* pv. *oryzae* (Xoo). Rice bacterial blight caused by Xoo is one of the most destructive diseases of rice worldwide.

### **Objectives**

Understanding which genes are required by *P. taiwanensis* to resist the leaf blight of rice pathogen *Xanthomonas oryzae* pv. *oryzae* (Xoo)

### **Methods**

Here we combined whole genome sequencing and Tn5-transposon mutagenesis to identify anti-Xoo toxin factors and related regulatory pathway. A high quality complete sequencing was accomplished by a combination of Roche 454, Illumina Solexa, Sanger sequencing and Optical mapping.

### **Conclusions**

The complete sequence of the 5.08-Mb genome sequence and 4666 CDS were determined. We used transposon random insertion to identify genes involved in the production and regulation of anti-Xoo activity based on analyses of 6000 individual insertion-strains. Our results show that the siderophore pyoverdine biosynthetic gene (*pvd*), Type VI secretion system (T6SS), and EnvZ/OmpR two-component system have important roles in antagonistic activity against Xoo. On the other hand, the toxicity of *P. taiwanensis* was negatively regulated by the RpoS sigma factor. We further used MALDI-imaging mass spectrometry (MALDI-IMS) to track pyoverdine in *P. taiwanensis* and mutants. The results showed that pyoverdine was positively regulated by EnvZ/OmpR two-component system and secreted by T6SS. In contrast, pyoverdine was negatively regulated by RpoS. To the best of our knowledge, this is the first report that Pyoverdine has toxicity toward Xoo and T6SS can secrete small compounds.

<sup>1</sup>Biological Science, Silla University, Busan, Korea

**Background**

IL-6 is a key proinflammatory cytokine which has been considered to be important in the pathogenesis of periodontal disease. Host modulatory agents directed at inhibiting IL-6, therefore, appear to be beneficial in terms of attenuating periodontal disease progression and potentially improving disease susceptibility.

**Objectives**

In the current study, we investigated the effect of flavonoid isorhamnetin on the production of IL-6 in murine macrophages stimulated with LPS from *P. intermedia*, a pathogen implicated in inflammatory periodontal disease, and its mechanisms of action.

**Methods**

LPS from *P. intermedia* ATCC 25611 was isolated by using the standard hot phenol-water method. Culture supernatants were collected and assayed for IL-6. We used real-time PCR to quantify IL-6 and HO-1 mRNA expression. HO-1 protein expression and levels of signaling proteins were monitored by immunoblot analysis. DNA-binding activity of NF- $\kappa$ B was analysed by using the ELISA-based assay kits.

**Conclusions**

Isorhamnetin significantly down-regulated *P. intermedia* LPS-induced production of IL-6 as well as its mRNA expression in RAW264.7 cells. Isorhamnetin upregulated HO-1 expression at both gene transcription and translation levels in *P. intermedia* LPS-activated cells. In addition, inhibition of HO-1 activity by SnPP blocked the inhibitory effect of isorhamnetin on IL-6 production. Isorhamnetin failed to prevent LPS from activating either JNK or p38 pathways.

Although further research is required to clarify the detailed mechanism of action, we propose that isorhamnetin may contribute to blockade of the host-destructive

processes mediated by IL-6, and could be a highly efficient modulator of host response in the treatment of inflammatory periodontal disease.

**NON-K1 SEROTYPES OF KLEBSIELLA PNEUMONIAE CAUSING LIVER ABSCESS AND ORGAN COMPLICATIONS IN HEALTHY MICE MODEL**

P. Y. Chung<sup>1</sup>, L. Kunaselan<sup>2</sup>, P. Krishnappa<sup>1</sup>, A. Barua<sup>3</sup>

<sup>1</sup>Pathology, International Medical University, Kuala Lumpur, Malaysia

<sup>2</sup>Medical Science, International Medical University, Kuala Lumpur, Malaysia

<sup>3</sup>Community Medicine, International Medical University, Kuala Lumpur, Malaysia

**Background**

*Klebsiella pneumoniae* is an opportunistic pathogen that affects immunocompromised patients and commonly associated with nosocomial infections. In the past two decades, the capsular serotype K1 has emerged as the predominant pathogen in causing liver abscess, affecting primarily Asians. While many studies have been reported for K1 and K2 which has comparable virulence to K1, very few of the 82 capsular serotypes have been studied.

**Objectives**

To determine the association between *K. pneumoniae* serotypes K1, K11, K19 and K31, and liver abscess and complications in kidney, spleen and lungs

**Methods**

Bacterial suspensions of the four serotypes of *K. pneumoniae* were inoculated intraperitoneally into healthy mice models. After 72 hours, the organs were aseptically removed, and histopathological examination and bacterial enumeration were carried out. The presence of liver abscess and complications in the other organs were characterized by the observation of necrosis and severity of inflammation, respectively.

**Conclusions**

From the histopathology examination, serotypes K1, K19 and K31 resulted in liver abscess, unlike K11. The spleen was severely inflamed with K1 and mildly inflamed with the other three serotypes. Moderate inflammation was observed in the lungs infected with K1 while the other serotypes caused mild inflammation. The immune system of the mice was able to clear the bacteria in all the organs within 72 hours when infected with all four serotypes. Our preliminary data supports a statistical association between non-K1 *K. pneumoniae* serotypes and liver abscess and organ complications in healthy mice models.

**THE EFFECTOR PROTEIN SDHA FROM PISCIRICKETTSIA SALMONIS IS OVEREXPRESSED DURING AN INFECTIOUS PROCESS IN CELL LINE SHK-1.**

M. Cortes<sup>1</sup>, C. Oliver<sup>1</sup>, R. Haro<sup>1</sup>, R. Sandoval<sup>1</sup>, R. Wirth<sup>2</sup>, A. Yañez<sup>1</sup>

<sup>1</sup>Facultad de Ciencias- Universidad Austral, Instituto de Bioquímica y Microbiología, Valdivia, Chile

<sup>2</sup>Achaea Centre- Regensburg University, Mikrobiologie-NWF III, Regensburg, Germany

**Background**

*Piscirickettsia salmonis* is the etiological agent of Piscirickettsiosis disease in Chilean Salmon farming and cause significant economic losses in this industry. For similar pathogens like *Legionella pneumophila* and *Coxiella burnetii* some effector proteins were described that modify cellular processes of the host to establish intracellular infection. Nowadays there is no evidence for similar effector proteins of *P. salmonis*. Only one report described a type 4b secretion system (SST4b) in this pathogen.

**Objectives**

Evaluate gene expression levels of *dotH*, *dotG* and *sdhA* genes during an infectious process induced by *Piscirickettsia salmonis* on SHK-1 cell line.

**Methods**

RNA extraction was performed combining Trizol with commercial kit for total RNA. RT reaction was performed with M-MLV and Real Time PCR was performed by commercial SYBR Green master mix kit.

**Conclusions**

The expression levels of *dotG*, *dotH* and *sdhA* genes are increased in a correlated manner between them during an infectious process induced by *Piscirickettsia salmonis*. At early times such 2 hours after infection the expression levels are increased and then decrease a few fold-change to increase again at the final days of infection but not as much as in the beginning of the experiment. From this pattern of gene expression we propose that the SST4b is involved in traslocating the effector protein SdhA to the cytoplasm of the infected cell.

**LIPL21 LEPTOSPIRAL PROTEIN BINDS EXTRACELLULAR MATRIX(ECM) COMPONENTS B2 INTEGRINS AND C3/C4 COMPLEMENT FACTORS**

M. Cosate<sup>1</sup>, G.H. Siqueira<sup>1</sup>, Z.M. Moraes<sup>1</sup>, S.A. Vasconcellos<sup>1</sup>, A.L.T.O. Nascimento<sup>1</sup>

<sup>1</sup>Biotechnology, Butantan Institute, São Paulo, Brazil

**Background**

Leptospirosis is a zoonosis with global distribution recognized as a re-emergent disease caused by pathogenic bacteria of the genus *Leptospira*. LipL21 is major leptospiral surface protein identified by proteomics.

**Objectives**

The goal of this work is to obtain the recombinant protein LipL21 expressed in *E. coli* and to evaluate its binding activity with extracellular matrix components (ECM), integrins cell receptors ( $\alpha$ L $\beta$ 2,  $\alpha$ M $\beta$ 2) and C3b and C4b complement factors.

**Methods**

The gene LIC10011 encoding for LipL21 was cloned and expressed in *Escherichia coli*. Protein attachment to individual ECM components,  $\alpha$ L $\beta$ 2,  $\alpha$ M $\beta$ 2 integrins, and C3b and C4b was screened by ELISA, and the binding was evaluated by probing the reaction with anti-LipL21 serum. Binding of LipL21 recombinant protein to ECM and integrins was compared with their binding to gelatin, BSA and fetuin negative controls, by using Student's two-tailed t-test.

**Conclusions**

LipL21 was expressed in *E. coli* with a 6X HIS sequence tag at N-terminal. The protein was present in its soluble form, and was successfully purified in Ni<sup>2+</sup>-charged resin, as assessed by SDS-PAGE. Binding of LipL21 was statistically significant with cellular fibronectin, collagen IV, laminin and  $\alpha$ L $\beta$ 2,  $\alpha$ M $\beta$ 2 integrins, which may be justified by the occurrence of *DGEA* integrin binding domain in LipL21 protein. The binding of LipL21 with C3b and C4b was significantly enhanced when the protein was associated with  $\alpha$ M $\beta$ 2 integrin, probably due the presence of binding sites for these components in the ligand. These results suggest that this protein has the potential to cooperate in the bacterial immune evasion and dissemination in the hosts.

## **CHARACTERIZATION OF VIRULENCE FACTORS IN ESCHERICHIA COLI ISOLATES FROM HAEMOCULTURES**

K. Curova<sup>1</sup>, M. Kmetova<sup>1</sup>, R. Vargova<sup>1</sup>, V. Hrabovsky<sup>1</sup>, L. Siegfried<sup>1</sup>

<sup>1</sup>Department of Medical and Clinical Microbiology,

Pavol Jozef Šafárik University in Košice Faculty of Medicine, Kosice, Slovakia

### **Background**

Extraintestinal pathogenic *Escherichia coli* (ExPEC) is one of the main etiological agents of Gram-negative bloodstream infections. Capacity of ExPEC to cause systemic infections is due to genes encoding virulence factors, which include adhesins, toxins, polysaccharide coatings, siderophores or iron acquisition systems.

### **Objectives**

The aim of our study was to analyse the presence of virulence genes *fimA*, *bfpA*, *pap*, *sfa*, *eae*, *afa*, *cnf1*, *α-hly*, *aer*, *ial*, *lt*, *st*, *ipaH*, *iucC*, *cdtI-V* and to determine the phylogenetic origin of *E. coli* strains isolated from septicemic patients.

### **Methods**

This study included 133 *E. coli* strains isolated by haemoculture from adult patients with bacteriemia. Automated blood culture system (Bactec 9050) was used in haemocultivation. *E. coli* strains of positive haemoculture were identified on a Microflex MALDI Biotyper (Bruker Daltonik) and confirmed by standard biochemical methods ENTEROtest 16, ENTERO-Rapid 24 (Lachema, Czech Republic). Polymerase chain reaction was used to detect virulence genes and to determine ECOR phylogenetic classification of *E. coli* strains.

### **Conclusions**

We found that *fim A* (96%), *aer* (75%) and *iucC* (68%) represent most common genes encoding virulence properties. Toxin studies revealed a relatively high incidence of *cnf1* (20%) and *α-hly* (19%). Phylogenetic classification showed that 80% of *E. coli* strains tested fall into phylogenetic groups B2 and D, representing main groups of virulent *E. coli*.

<sup>3</sup>Center for Bioinformatics and Computational Biology, University of Maryland Institute for Advanced Computer Studies, College Park MD, USA

<sup>4</sup>Microbiology and Immunology, Institute for Genome Sciences University of Maryland School of Medicine, Baltimore MD, USA

<sup>5</sup>Microbiology and Immunology, Center for Vaccine Development University of Maryland School of Medicine, Baltimore MD, USA

### **Background**

Enterotoxigenic *Escherichia coli* is leading cause of diarrhea, mainly in children and travelers to endemic regions. Currently, there is no effective vaccine to prevent ETEC-caused diarrhea. ETEC colonizes the small intestine by using a diverse set of adhesins including about twenty different pili. However, between 15-50% of the isolates obtained from diarrhea cases worldwide are negative in detection of the known adhesins, suggesting presence of additional unidentified adherence determinants and, at the same time, presenting an obstacle in the development of adhesin-based vaccine candidates.

### **Objectives**

To identify novel fimbrial loci in ETEC strains negative for detection of the known adhesins

### **Methods**

Genomes of 35 ETEC strains isolated from diarrhea cases in Chile (14 isolates), Kenya (5), Mozambique (2), The Gambia (1), Mali (3), Bangladesh (3), India (2) and Pakistan (5), which were negative in detection of 23 adhesin genes, were partially sequenced by a paired-end protocol (Illumina, HiSeq 2000). Genomic sequences were screened for 161 fimbrial usher genes belonging to nine families of fimbriae (alpha, beta, gamma-1, gamma-2, gamma-3, gamma-4, kappa, sigma and pi), in order to locate homologous genes and find putative novel loci encoding usher/chaperone assembled adhesins. Genomic sequences of non- pathogenic *E.*

*coli* strains (13) and other ETEC strains (H10407, E24377A and B7A) were included as controls.

### **Conclusions**

Loci encoding putative novel gamma-2 fimbriae were found in 23 strains, being frequent among ETEC strains negative for detection of known adhesins.

## Bacterial pathogenicity

### COORDINATED REGULATION OF THE MAJOR VIRULENCE GENE *pelD* OF THE PHYTOPATHOGEN BACTERIUM *DICKEYA DADANTII* BY FIS, CRP AND H-NS

*A. Duprey*<sup>1</sup>, *S. Reverchon*<sup>1</sup>, *W. Nasser*<sup>1</sup>

<sup>1</sup>UMR5240 CNRS/INSA/UCB, Université de Lyon, Villeurbanne, France

#### Background

Pathogenic bacteria tightly regulate their virulence genes in response to the variations of their environment. Many transcription factors have been identified for such genes, but their interactions remain poorly understood. The *pel* genes of the phytopathogen bacterium *D. dadantii* are a good example of this situation, with a dozen identified regulators, yet an integrative view of their action was lacking.

#### Objectives

As a first step towards an integrative model, this work aims at taking into account the interactions between the major global regulators of virulence (Fis, CRP and H-NS) in the regulation of the *pelD* virulence gene. In particular, Fis has 2 sites overlapping the promoter (-34 and -10 from the transcription start site) and an upstream site (-126). The relationships between those sites are investigated here as well.

#### Methods

Binding sites were inactivated individually by site-directed mutagenesis and the impact of the modifications was evaluated both *in vivo* by *gfp* gene fusion measurements, and *in vitro* by quantitative DNase I, potassium permanganate footprinting and *in vitro* transcription.

#### Conclusions

*D. dadantii* has established 3 redundant mechanisms to ensure a full repression of *pelD* in exponential phase : 2 of the Fis binding sites (-34 and -10) directly compete with RNA polymerase, 1 Fis site (-34) prevents the activator CRP from binding and a Fis-regulated (involving the -126 Fis site) reverse promoter represses the *pelD* promoter. On top of this, H-NS modulates the action of Fis. These results show that the importance of interactions in transcriptional regulation should not be underestimated.

<sup>3</sup>*Department of Surgery, Shuang Ho Hospital Taipei Medical University, Taipei,  
Taiwan*

**Background**

The phenotype of *Salmonella yqiC* gene and its impacts on host responses are little known.

**Objectives**

To investigate whether *yqiC* is responsible for *Salmonella* colonization/invasion, bacterial motility/adherence, and interleukin (IL)-8/human  $\beta$ -defensin-3 (hBD3) production in human intestinal epithelium.

Fig. 1

Fig. 2

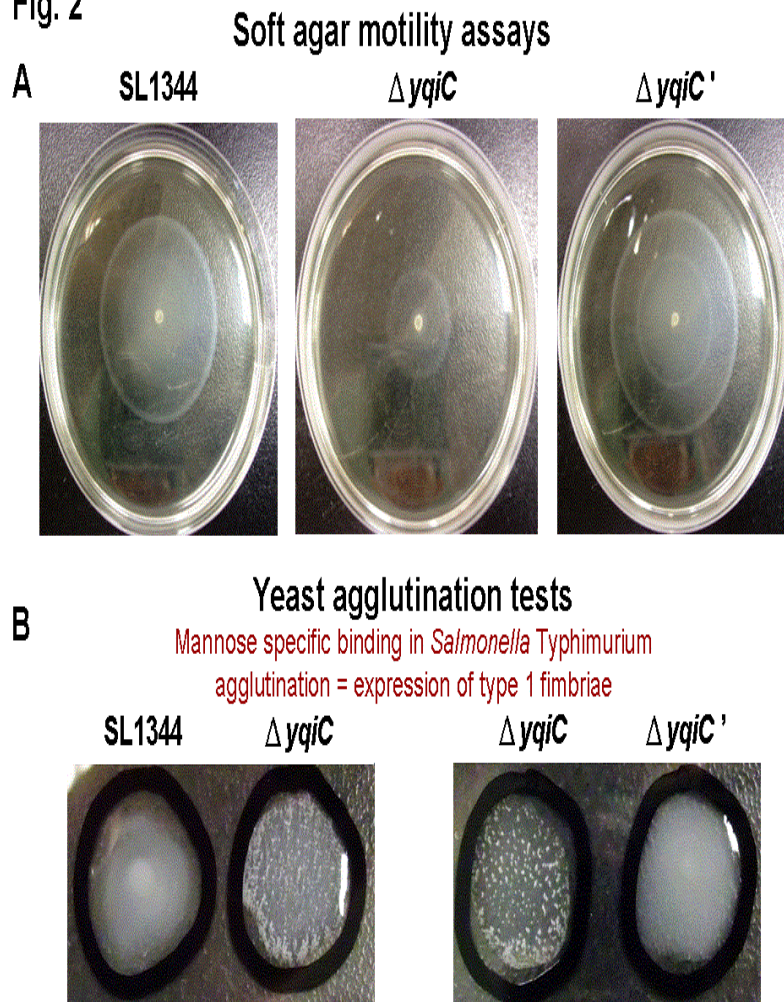

Fig. 3

## Methods

HeLa, Caco-2, LS174T, and THP-1 cells were infected with *Salmonella* Typhimurium

wild-type SL1344, *yqiC*-depleted mutant  $\Delta yqiC$ , its complemented strain  $\Delta yqiC'$ , and *fliC*-deleted mutant  $\Delta fliC$  (MOI=5) for 2 hours, and treated with plain medium (output pool A: colonizing bacteria) or gentamicin (output pool B: invading bacteria) for 1 hour. At these times cell-associated bacterial numbers were calculated. Next, motility and adherence of these strains were examined by soft agar motility assays and yeast agglutination tests. Last, LS174T cells were treated with these strains, flagellin, and IL-1 $\beta$  for 2 hours, incubated in gentamicin for 1 hour, and the infections were continued for 15 hours. At the end-point, the supernatants were collected to measure IL-8 and hBD3 using ELISA.

## **Conclusions**

Compared with SL1344,  $\Delta yqiC$  was attenuated in bacterial colonization and invasion in 4 cells (Fig.1), lost swimming ability (Fig.2A), and constitutively expressed type 1 fimbriae (Fig.2B). IL-8 production in  $\Delta yqiC$ -infected cells was lower than that in SL1344-infected cells, with lower levels than those in  $\Delta fliC$ -infected cells (Fig.3A). Furthermore,  $\Delta yqiC$  and  $\Delta fliC$  induced lower hBD3 secretion than SL1344 did in LS174T cells (Fig.3B).

In conclusion, *yqiC* is required for *Salmonella* Typhimurium colonization, and host IL-8 and hBD3 production. This is mediated by its modulation in *Salmonella* motility and flagellation via downregulation of type 1 fimbriae.

## **ROLE OF FIBRONECTIN IN THE ADHERENCE OF DIARRHEAGENIC *E. COLI* TO INTESTINAL CELLS AND THE INDUCTION OF SECRETION OF PRO-INFLAMMATORY CYTOKINES**

*D. Yañez<sup>1</sup>, M. Izquierdo<sup>1</sup>, M. Farfan<sup>1</sup>*

<sup>1</sup>*Pediatrics, Universidad de Chile, Santiago, Chile*

### **Background**

Fibronectin has been shown to be important for the adherence of diarrheagenic *E. coli* (DEC), but the biological relevance of the DEC-fibronectin-mediated interaction to intestinal cells remains unclear

### **Objectives**

We evaluated the impact of the DEC-fibronectin-mediated interaction on the induction of secretion of pro-inflammatory cytokines

### **Methods**

We assessed the ability of EAEC, ETEC and EHEC to bind to HEp-2 cells in the presence or absence of purified fibronectin protein and we quantified the amount of IL-8 secreted by infected cells. Additionally, we quantified the expression of *FOS*, *NFkB*, *IL8*, *CCL20*, *IL1A* and *TNFalpha* genes. Alternatively, we quantified the IL-8 secretion of HEp-2 cells transfected with small hairpin RNA (shRNA) for fibronectin or scrambled shRNA infected with EAEC strain.

### **Conclusions**

We found a significant increase in the adherence to HEp-2 cells pre-incubated with fibronectin compared with cells not incubated with this protein for all DEC assayed. However, the IL-8 secretion was significantly reduced in the presence of fibronectin. Real-time PCR assay indicated that of all genes assayed only *IL8* gene expression was reduced in HEp-2 cells pre-incubated with fibronectin. Experiments using fibronectin shRNA revealed a decrease in the EAEC adherence to cells, but no changes in the IL-8 secretion.

Overall, all data suggested that fibronectin participates exclusively in the adherence of DEC to epithelial cells, but not in the inflammation originated as a consequence of the infection.

### **ARO<sup>A</sup> DEFICIENT SALMONELLA – MORE THAN AN AUXOTROPHIC MUTANT?**

S. Felgner<sup>1</sup>, M. Frahm<sup>1</sup>, M. Erhardt<sup>2</sup>, R. Curtiss III<sup>3</sup>, S. Häussler<sup>4</sup>, S. Weiss<sup>1</sup>

<sup>1</sup>Molecular Immunology, Helmholtz Centre for Infection Research, Braunschweig, Germany

<sup>2</sup>Infection Biology of Salmonella, Helmholtz Centre for Infection Research, Braunschweig, Germany

<sup>3</sup>Infectious Diseases and Vaccinology, Biodesign Institute, Tempe, USA

<sup>4</sup>Molecular Bacteriology, Helmholtz Centre for Infection Research, Braunschweig, Germany

#### **Background**

Attenuated *Salmonella* employed as live vaccine carrier could provide protection against many infectious diseases. To guarantee successful vaccination, balance between attenuation and immunestimulation is required. Since aromatic amino acids are not freely available in the host,  $\Delta$ aroA is commonly used as an attenuating factor. However, we observed that an aroA deficiency also dramatically modified the phenotype of *Salmonella* by increasing bacterial virulence.

#### **Objectives**

In the present work the molecular basis for the phenotypic changes in the strains should be determined by transcriptional profiling and gene deletion of apparently relevant genes.

#### **Methods**

We were able to demonstrate via transcriptome profiling that *Salmonella* is consuming excessive pyruvate by up-regulating sugar pathways like *manXYZ* or *glpABCQT* resulting most likely in an osmotic imbalance. Furthermore, aroA deficient mutants are more prone to express FljB flagella. These metabolic dysregulations could be a possible explanation for the observed phenotype of increased virulence. In accordance after intravenous application of  $\Delta$ aroA *Salmonella* to mice (86/609/EEC), significantly increased induction of pro-inflammatory cytokines like TNF- $\alpha$  or IFN- $\beta$  was observed emphasizing the importance of this deletion for *Salmonella*'s phenotype. We also employed such bacteria in bacteria-mediated tumor therapy. We could show that the  $\Delta$ aroA strains display an increased tumor colonization and an improved anti-tumor response.

#### **Conclusions**

Disturbing the bacterial metabolism by mutating aroA in *Salmonella* leads to a modified phenotype that results on one site in attenuation but also improves *Salmonella*'s ability to induce an immune response. Therefore this mutation might be a preferable modification for vaccine and cancer research.

**THE CAPSULE OF CAMPYLOBACTER JEJUNI PREVENTS BINDING TO SIGLEC-1 AND SIGLEC-7**

S. Franch-Arroyo<sup>1</sup>, R. Huizinga<sup>2</sup>, B.C. Jacobs<sup>2</sup>, H.P. Endtz<sup>1</sup>, A.P. Heikema<sup>1</sup>

<sup>1</sup>Medical Microbiology and Infectious Diseases,

Erasmus MC University Medical Center, Rotterdam, Netherlands

<sup>2</sup>Immunology, Erasmus MC University Medical Center, Rotterdam, Netherlands

**Background**

*Campylobacter jejuni* (*C. jejuni*) is the leading cause of bacterial gastroenteritis worldwide. Besides diarrhoea, an infection with *C. jejuni* can precede the acute and severe polyneuropathy Guillain-Barré syndrome (GBS). Lipooligosaccharides (LOS), present in the outer membrane of *C. jejuni*, cause activation of the innate immune system and sialylation of LOS is critical for the induction of GBS. Sialylated LOS can be recognised by two host immune-receptors, Siglec-1 and Siglec-7. Recent research indicates that *C. jejuni* LOS are not always exposed to the external environment. We hypothesize that *C. jejuni* exploits the polysaccharide capsule as an evasion strategy to prevent immune recognition mediated by Siglec-1 and Siglec-7.

**Objectives**

To determine whether the polysaccharide capsule of *C. jejuni* prevents the specific binding of bacterial LOS to Siglec-1 and Siglec-7.

**Methods**

Capsule and sialic acid transferase knock-out mutants were generated. Bacteria were FITC-labelled, incubated with Siglec-1 or Siglec-7 transfected cells and binding of live or heat-inactivated bacteria was measured using flow cytometry.

**Conclusions**

Absence of the capsule of *C. jejuni* enhanced binding of *C. jejuni* sialylated LOS to Siglecs. For Siglec-1, this was observed for both live and heat-inactivated bacteria. In contrast, for Siglec-7 the difference in binding between wild-type and non-capsulated *C. jejuni* was only observed for live bacteria. Sialic acid mutants showed lower binding to Siglecs. Our results give insight in how the immune system recognizes *C. jejuni* and define the capsule as a bacterial factor that may influence the onset of GBS.

<sup>3</sup>Structural and Molecular Microbiology, Vrije Universiteit Brussel, Brussels, Belgium

<sup>4</sup>Sciences et Technologies, CNRS - Université de Lille, Lille, France

### **Background**

*Brucella abortus* is a facultative intracellular pathogen for mammals. Many aspects of its intracellular trafficking have been investigated in HeLa cells and RAW264.7 macrophages. However very little is known about its cell cycle regulation, except that bacteria are blocked in G1 phase during early hours of infection.

### **Objectives**

The main goal of this project is to investigate the regulon of CtrA, a central transcription factor.

We also decided to investigate a two-component system (TCS) located upstream of a signalling pathway regulating CtrA phosphorylation status. This TCS involves a histidine kinase, PdhS, and a single-domain response regulator, DivK (Hallez).

### **Methods**

We used RSA-Tools (Van Helden) to look for the consensus sequence bound by CtrA in *B. abortus* genome. This *in silico* approach allowed the prediction of a long list of putative CtrA targets. A ChIP-seq analysis confirmed part of these targets. The activity of some of these promoters was monitored by fusing them to a gene coding for an unstable GFP.

We performed *in vitro* kinase assays to test PdhS autophosphorylation and its ability to transfer the phosphate group to DivK.

### **Conclusions**

Promoters bound by CtrA are predicted to control genes involved in cell cycle regulation, such as division, chromosome replication and segregation.

The reporter system showed that the activity of some promoters varies in bacteria grown in rich culture medium according to their cell size, as well as during *B. abortus* intracellular trafficking in HeLa cells.

*In vitro* kinase assays show that PdhS can autophosphorylate and quickly transfer its phosphate group to DivK.

## **THE DUAL BEHAVIOUR OF CARBON STARVATION GENES PROVIDES A LINK BETWEEN METABOLISM AND PATHOGENESIS OF SALMONELLA**

P. Garai<sup>1</sup>, D. Chakravorty<sup>1</sup>

<sup>1</sup>Department of Microbiology and Cell Biology, Indian Institute of Science, Bangalore, India

### **Background**

The ability of the enteric pathogen *Salmonella* to utilize a diverse set of nutrients, allows it to survive in various nutrient limiting conditions, rendering it one of the most successful pathogens. *Salmonella* employs sophisticated machinery to either acquire a specific nutrient from the surrounding environment or modify the host's ecosystem for its own metabolic benefit. Carbon starvation (*cst*) genes represent one such class that are proposed to be expressed during carbon starvation, the most common stress encountered by *Salmonella*. Two *cst* genes, *cstA* and *yjiY*, predicted to mediate peptide utilization, were previously reported to be regulated by the global regulator CsrA and YehU/YehT two-component system in *E. coli*.

### **Objectives**

In *Salmonella*, *cstA* was shown to be required for virulence in *C. elegans*, however, the underlying mechanism remains unknown. The objectives of this study are to establish the role of *cst* genes in metabolism and to understand how they affect *Salmonella* pathogenesis.

### **Methods**

We generated knockout for the genes *cstA* and *yjiY* in *Salmonella* Typhimurium. Phenotype microarray on various nutrient sources along with transcriptome analysis was carried out for wild-type and knockout strains. Virulence was assessed using cell culture and animal models.

### **Conclusions**

Phenotype microarray confirmed the importance of *cst* genes in metabolism of *Salmonella*. Despite the high similarity in their sequences, *cstA* and *yjiY* displayed different effects on motility, adhesion, biofilm forming ability and virulence in the animal model of infection. This study brings forward pleiotropic role of *cst* genes and highlights the crucial cross-talk between metabolism and pathogenesis of *Salmonella*.

## **TRANSCRIPTOMIC ANALYSIS IN SALMONELLA ENTERICA REVEALS PRODUCTS OF THE STD FIMBRIAL OPERON AS GLOBAL REGULATORS OF GENE EXPRESSION**

L. García Pastor<sup>1</sup>, E. Puerta-Fernández<sup>2</sup>, J. Casadesús<sup>1</sup>

<sup>1</sup>Genética, Universidad de Sevilla, Sevilla, Spain

<sup>2</sup>Abengoa Research, Abengoa, Sevilla, Spain

### **Background**

Fimbriae are virulence factors in *Salmonella enterica*, playing diverse roles in bacterial adhesion (Humphries et al. *FEMS microbiology letters*, 201:121-125, 2001). Synthesis of Std fimbriae, that are not expressed under laboratory conditions, has been shown to occur in the animal intestine, but the molecular mechanisms involved remain unknown (Weening et al. *Infection and immunity*, 73:3358-3366, 2005). It was previously described that derepression of the *std* operon occurs in DNA adenine methylase (*dam*) mutants and that HdfR, a poorly known LysR-like factor, is necessary for *std* transcription. However, HdfR-mediated activation of *std* transcription occurs only in a fraction of the bacterial population, suggesting the occurrence of either bistable expression or phase variation (Jakomin et al. *Journal of bacteriology*, 190:7406-7413, 2008).

### **Objectives**

This work aims to further understand the molecular mechanisms that might allow expression of the *std* operon inside the animal and to analyze the effect of its expression in *S. enterica*.

### **Methods**

A genetic screen for additional *std* regulators revealed that the *std* operon itself is a positive regulator, and the downstream genes of the operon, *stdE* and *stdF*, are crucial for this control. Surprisingly, transcriptomic analysis revealed that StdE and StdF control a plethora of *S. enterica* loci including genes involved in motility, chemotaxis, biofilm formation, conjugation, and virulence.

### **Conclusions**

StdEF-mediated control may play a role in the crosstalk between motility, adhesion and invasion, considered essential for optimal *Salmonella* infection. If StdEF expression is subjected to phase variation during infection, subpopulation formation can be expected to occur in the animal intestine.

**IDENTIFICATION OF GENES MODULATING THE INNATE IMMUNE RESPONSE OF MAMMARY EPITHELIAL CELLS TO ESCHERICHIA COLI P4**

P. GERMON<sup>1</sup>, C. BERTHAULT<sup>1</sup>, M. REPERANT<sup>1</sup>, P. CUNHA<sup>1</sup>, F.B. GILBERT<sup>1</sup>, P. RAINARD<sup>1</sup>

<sup>1</sup>UMR 12828 ISP, INRA, Nouzilly, France

**Background**

Despite continuous efforts to reduce its incidence, mastitis remains a major disease in dairy cows. Main mastitis pathogens include *Streptococcus uberis*, *Staphylococcus uberis* and *Escherichia coli*.

Induction of the innate immune response is a key mechanism in the initiation of the host response during infections of the mammary gland in cows by *Escherichia coli*.

*E. coli* P4 is a prototypical mastitis strain isolated from a case of clinical mastitis. Previous studies showed that *E. coli* P4 was virulent in a mouse model of mastitis. Yet, we have found that this strain induced a reduced pro-inflammatory response in mammary epithelial cells (MEC) compared to other *E. coli* isolates.

**Objectives**

Our objective was to identify genes responsible for the low pro-inflammatory response induced in MEC by *E. coli* P4 and determine if this reduced pro-inflammatory response contributed to the virulence of *E. coli* P4 in a murine mastitis model.

**Methods**

By screening a library of 2000 mutants for increased pro-inflammatory response on MEC, we identified a series of mutations that increase the response of MEC to strain P4. The impact of these mutations on the phenotype of *E. coli* P4 will be presented in details and discussed.

**Conclusions**

Altogether, results presented will allow a better understanding of the initial steps of the interaction between mammary epithelial cells and mastitis pathogens. This work will help understand if the low pro-inflammatory response triggered by *E. coli* P4 contributes to its virulence.

## **GARDNERELLA VAGINALIS AS A TRIGGER OF RECURRENT E. COLI UTI**

N.M. Gilbert<sup>1</sup>, V.P. O'Brien<sup>1</sup>, A.L. Lewis<sup>1</sup>

<sup>1</sup>*Molecular Microbiology, Washington University, St. Louis, USA*

### **Background**

Recurrent urinary tract infection (**rUTI**), most often caused by uropathogenic *Escherichia coli* (**UPEC**), is a life altering, potentially life threatening problem for many women. Asymptomatic carriage of UPEC in bladder reservoirs has long been believed to be a source for rUTI. However, the natural triggers of UPEC emergence from these reservoirs have remained mysterious. Women with bacterial vaginosis (**BV**), an imbalance of the vaginal microbiota, are at increased risk for UTI.

### **Objectives**

We sought to address the long-standing idea that UPEC bladder reservoirs seed rUTI and to understand why women with BV are more prone to UTI. Translocation of BV bacteria to the urinary tract is likely to occur during sexual activity, which is often a prelude to rUTI. We tested the hypothesis that bladder exposure to BV-associated bacteria may initiate UPEC emergence from intracellular reservoirs.

### **Methods**

Mice containing UPEC bladder reservoirs were challenged by transurethral inoculation with either PBS (control) or the BV-associated bacterium *Gardnerella vaginalis*. We monitored the consequences of bladder exposure to *G. vaginalis* by 1) enumerating urinary tract bacterial titers, 2) assessing epithelial exfoliation by immunofluorescence and scanning-electron microscopy and 3) RNAseq analysis.

### **Conclusions**

Here we show that *G. vaginalis* triggers bladder epithelial exfoliation and emergence of *E. coli* from intracellular reservoirs. We observed phenotypes consistent with rUTI, including high UPEC titers and neutrophils in urine.. These data strongly suggest that *G. vaginalis* presence within the urogenital microbiota may be a trigger for rUTI and likely contributes to the substantially increased risk of UTI in women with BV.

<sup>2</sup>Faculty of Science and Letters Department of Molecular Biology and Genetics, Yeni Yuzyil University, Istanbul, Turkey

<sup>3</sup>Medical Faculty Medical Biology and Genetics Department, Yeni Yuzyil University, Istanbul, Turkey

**Background:** The gene expression of microorganisms and environmental factors are closely related.

**Objectives:** To investigate possible changes in the gene expression levels of virulence genes [*sfa/foc* (S and F1C fimbriae), *cnf 1* (cytotoxic necrotizing factor), and *usp* (uropathogenic-specific protein)] in a uropathogenic *E. coli* standard strain (UPEC C7) in the presence of insulin and glucose.

**Methods:** The UPEC strain was cultured in broth media (tryptic soya broth-TSB) under 5 different conditions: 0.1% glucose, 20µU insulin, 200µU insulin, 0.1 % glucose+200µU insulin, and control TSB. After incubation for 24 hours at 37°C, total RNA isolations were prepared from all five bacteria cultures. Gene expression levels were determined by quantitative PCR. Changes in gene expression were evaluated using the expression levels of 16sRNA as a “housekeeping gene,” according to the Pfaffl equation.

**Conclusions:** The medium containing 0.1 % glucose+200µU insulin had increased expression levels of all three genes in the *E. coli* C7 strain. In contrast, the other media (0.1% glucose, 20µU insulin, 200µU insulin) had a decrease in the expression levels of virulence genes, all compared to control medium.

This investigation shows that some environmental factors, such as glucose and insulin, could determine the pathogenicity of *E. coli* strains.

<sup>2</sup>Department of Clinical Chemistry and Hematology, University Medical Center Utrecht, Utrecht, Netherlands

<sup>3</sup>Department of Environmental Health Sciences, University Medical Center Freiburg, Freiburg, Germany

**Background**

*Enterococcus faecium* is a commensal of the mammalian gastrointestinal tract. Recently, it has become an important nosocomial pathogen, causing infections that are difficult to treat. However, little is known about the mechanisms that *E. faecium* employs to colonize and infect mammals.

**Objectives**

We aimed to clarify the interactions of *E. faecium* with the host and we hypothesized that genes important for colonization and infection, could exhibit temperature-regulated expression control.

**Methods**

We performed a transcriptome analysis of *E. faecium* E1162, during mid-exponential growth at 25°C and 37°C. Furthermore, we functionally characterized a surface protein of *E. faecium*, that was found to be produced at higher levels during growth at 37°C than at 25°C.

**Conclusions**

We found thirty-three genes expressed significantly higher at 37°C compared to 25°C. One of the most highly upregulated genes (4.4-fold), is predicted to encode a peptidoglycan-anchored surface protein. The N-terminal domain of this protein is unique to *E. faecium* and closely related enterococci. The C-terminal domain contains

three proline-rich repeats, leading us to name the protein PrpA for proline-rich protein A. PrpA is a surface-exposed protein, that was maximally produced in exponentially growing cells at 37°C. PrpA is immunogenic as specific antibodies were observed in patients after they suffered from an *E. faecium* bacteremia. Heterologously expressed and purified PrpA was able to bind to fibrinogen, fibronectin and to platelets. Furthermore, a *prpA* deletion mutant was defective in the early stages of biofilm formation. Our data indicate that PrpA may contribute to the pathogenesis of *E. faecium* infections in hospitalized patients.

T. Uebanso<sup>1</sup>, K. Mawatari<sup>1</sup>, A. Takahashi<sup>1</sup>

<sup>1</sup>Preventive Environment and Nutrition,

Univ of Tokushima Grad Sch of Health Biosciences, Tokushima, Japan

**Background**

The intestinal epithelium provides a physical barrier to luminal bacteria. This barrier serves as the first line of defense against bacterial adhesion and invasion.

*Campylobacter jejuni* is a Gram-negative commensal bacterium in domestic animal and cause gastrointestinal foodborne disease in human. *C. jejuni* is able to adhere and invade gut epithelium, which lead cause of acute gastroenteritis in human. It has believed that the function of tight junctions (TJs) in human intestinal epithelium is closely related with invasion of *C. jejuni*.

**Objectives**

The aim of this study was to investigate interaction between *C. jejuni* and host intestinal barrier functions. In this study, we used cultured islands (unpolarized) and sheets (polarized) form Caco-2cell.

**Methods**

Invasion of *C. jejuni* was measured by gentamycin protection assay in Caco-2 cells. Confocal microscopy was used to examine the localization of internalized bacteria. And the most of bacteria were observed on cellular lateral part in islands of cell. Interestingly, *C. jejuni* efficiently invaded from basolateral surface compared with apical surface and intracellular *C. jejuni* was significantly increased in disruption of TJs by the treatment with EGTA. Furthermore, *C. jejuni* infection induced the distribution of the TJs component.

**Conclusions**

These date indicated that the TJs formed by each of neighboring cells might act as physical barrier for prevention of *C. jejuni* invasion, and infection of *C. jejuni* might effect on formation of TJs component. These results suggested that the *C. jejuni* infection inducible TJs disruption might enhance *C. jejuni* invasion into host cell.

## **CAPNOCYTOPHAGA CANIMORSUS IS ADHERING TO HOST MEMBRANE GLYCOPROTEINS**

E. Hess<sup>1</sup>, F. Renzi<sup>1</sup>, G.R. Cornelis<sup>1</sup>

<sup>1</sup>URBM, UNamur, Namur, Belgium

### **Background**

*Capnocytophaga canimorsus* (Cc), member of the *Bacteroidetes* phylum, is an oral commensal from dogs which causes rare but severe infections in humans. Cc feeds on sugar moieties of glycoproteins expressed on host cell membranes. Removal of N-linked glycans is achieved by the glycoprotein deglycosylation (Gpd) complex encoded by a polysaccharide utilization locus, a hallmark of *Bacteroidetes*.

### **Objectives**

The aim of this study is to determine whether Cc is adhering to the host cells it is feeding on and, if so, which mechanisms are implicated.

### **Methods**

Cell lines were infected with strain Cc5. Mutant bacteria were constructed by site-directed gene replacements. Adhesion was monitored by microscopy and flow cytometry.

### **Conclusions**

Cc5 adheres to epithelial, endothelial and immune cells. In *Flavobacterium johnsoniae*, another member of the *Bacteroidetes* phylum, gliding motility and adhesion are associated. In Cc5 adhesion was not abrogated in a mutant unable to glide. Adhesion of Cc5 was mainly mediated by the Gpd complex. Cc5 adhered to host cells via the membrane glycoproteins as inhibition of protein glycosylation by tunicamycin led to a decreased adhesion. Removal of serum from the assay, leaving cell glycoproteins as the only feeding source, increased adhesion. If fetuin, a glycoprotein deglycosylated by Cc5, was added to the serum-depleted medium, adhesion decreased. We conclude that adhesion of Cc5 to cells is linked to feeding through the Gpd complex. Further work will be conducted to find out whether adhesion could be important during infection.

<sup>5</sup>Infection Immunity & Inflammation, University of Leicester, Leicester,  
United Kingdom

**Background**

Members of the *Mycobacterium tuberculosis* complex are the causative agents of tuberculosis, a major global health threat. The majority of individuals are thought to be infected latently whereby the bacteria are in a non-replicating dormant state, and the individual is asymptomatic. Many of the proteins secreted by this organism have been shown to be essential for the virulence, survival and dormancy, and function in a variety of different roles. The resuscitation promoting factors (Rpfs) are one such family of proteins whose peptidoglycan hydrolyzing activities have been correlated with the resuscitation of dormant bacteria; however, the precise molecular mechanisms underlying this process remain poorly understood.

**Objectives**

The aim of this work is to gain insight into the expression and localisation patterns of Rpfs during bacterial growth and macrophage infection.

**Methods**

We have generated a number of Rpf deletion mutants and Rpf specific polyclonal antibodies to monitor Rpf expression *in vitro* using flow cytometry, and during *Mycobacterium marinum* infection of murine macrophages by immunofluorescence and confocal microscopy.

**Conclusions**

Having observed Rpfs at the level of individual bacteria, we conclude that a subset of

the mycobacterial population express Rpf at a detectable level during *in vitro* growth, and the infection process.

<sup>1</sup>Department of Biochemistry and Microbiology,  
University of Chemistry and Technology Prague, Prague 6, Czech Republic

**Background**

*Cronobacter* spp. was proposed as a new genus in 2008. All the members of *Cronobacter* are considered to be potentially pathogenic; however recent epidemiological studies indicated differences in virulence. The most often isolated species from clinical samples were *C. sakazakii* and *C. malonaticus*. Some reports revealed the connection between sequence type and virulence of particular strain. It has been shown that sequence type 4 (ST4 – *C. sakazakii*) is prevalent for meningitides, ST7 (*C. malonaticus*) is often associated with adult infections. These sequence types are considered as the evidence of virulence.

**Objectives**

The objectives of this work were to implement PCR specific for virulent proteins and to reveal connection between sequence type (MLST) and virulence genes.

**Methods**

Several factors responsible for virulence were targeted: the system for iron acquisition, outer membrane protein A, haemolysin and metalloprotease placed on chromosome and type six secretion system, secretion system FHA and outer membrane protease placed on plasmids.

PCR protocols for the detection of corresponding genes were applied to all *Cronobacter* species and compared with determined sequence type.

**Conclusions**

The predominance of some virulence genes was observed within particular species, in some cases even with sequence type; for example, haemolysin was detected in all tested *C. sakazakii* strains and in *C. malonaticus* presenting sequence type 7.

This work was supported by the Czech Grant Agency (13-23509S).

## **OUTER MEMBRANE PROTEIN 1 P1 IS THE CEACAM-BINDING ADHESIN OF HAEMOPHILUS INFLUENZAE**

A. Kengmo Tchoupa<sup>1</sup>, S. Lichtenegger<sup>2</sup>, J. Reidl<sup>2</sup>, C.R. Hauck<sup>1</sup>

<sup>1</sup>Lehrstuhl für Zellbiologie, Universität Konstanz, Konstanz, Germany

<sup>2</sup>Institute of Molecular Biosciences, University of Graz, Graz, Austria

### **Background**

*Haemophilus influenzae* (*Hinf*) is a Gram-negative pathogen colonizing the upper respiratory tract mucosa. *Hinf* belongs to a group of human-restricted bacteria, which bind to carcinoembryonic antigen related cell adhesion molecules (CEACAMs) on epithelial cells. Adhesion to CEACAMs is thought to be mediated by the *Hinf* outer membrane protein (OMP) P5 promoting establishment of the pathogens in the human nasopharynx.

### **Objectives**

Aiming at preventing *Hinf* colonization, we sought to identify the molecular requirements for *Hinf* binding to CEACAMs.

### **Methods**

Binding assays with soluble receptor ectodomains, followed by flow cytometric analysis or Western Blotting, were used to characterize CEACAM-binding profiles of wildtype and mutant *Hinf*. OMP P1, and not OMP P5, was identified as the CEACAM-binding adhesin. Multiple amino acid sequence alignment of P1 combined to heterologous expression of wild-type, chimeric, or mutated P1 in *E. coli* depicted the molecular details of the P1-CEACAM interaction.

### **Conclusions**

Surprisingly, *Hinf* P5 mutants still avidly bind CEACAMs and *Hinf* P5 expressed in *E. coli* fails to mediate CEACAM targeting. Instead, a genetic screen identifies *Hinf* P1 as the CEACAM-binding adhesin. Deletion of P1 in *Hinf* and heterologous expression in *E. coli* demonstrate that P1 is necessary and sufficient to bind several human CEACAMs. Concordantly, when expressed on the surface of *E. coli*, P1 promotes adhesion to and invasion into epithelial cells. Structure-activity relationship investigations with P1 mutants demonstrate that several flexible extracellular loops allow P1 to engage human CEACAMs. These results provide the first evidence for the involvement of the major outer membrane protein P1 of *Hinf* in pathogenesis.

<sup>3</sup>*Institute of Pathology, Medical University Graz, Graz, Austria*

<sup>4</sup>*Departments of Medicine and Microbiology, New York University School of Medicine, New York, USA*

### **Background**

Despite its late-in-life pathogenicity (gastric cancer and peptic ulcer disease), due to its potential early-life benefits (protection against childhood-onset asthma, diarrheal disease, and reflux esophagitis), *Helicobacter pylori* (*Hp*) might be considered a commensal. The ongoing disappearance of *Hp* from the human microbiome is concerning as little is known about the influence of *Hp* on the host's microbiome and immunity.

### **Objectives**

In this study, we aimed to investigate the interactions of *Hp* with its host in a mouse model.

### **Methods**

We infected C57/Bl6 mice with *cagA*+ *Hp* PMSS1, or not (control). Groups of mice were serially sacrificed over a period of 6 months and host responses analyzed.

### **Conclusions**

All inoculated mice were *Hp*-positive when sacrificed, as verified with PCR and culture and displayed gastric histology typical for *Hp* colonization. All infected mice showed high levels of IgM/IgG to *Hp* but not to CagA. Nanostring® analysis, performed on stomach and lung, revealed a large number of immune genes in the stomach with increased expression. Immune gene expression was also altered in the lung and flow-cytometry confirmed significantly higher levels of Th17-cells in infected mice compared to controls. Extracted DNA from fecal pellets, gastric, ileal and cecal contents were subjected to 16S rRNA gene sequencing to determine changes in the microbiome due to *Hp* colonization. Overall, control and colonized mice displayed

different population structures in both their gastric and intestinal microbiota. These findings indicate that in this mouse model, *Hp* influences both the microbial population structure and local and distant host immune responses.

<sup>3</sup>Chest Diseases, Istanbul University Cerrahpasa Medical Faculty, ISTANBUL, Turkey

<sup>4</sup>Immunology, Istanbul University Cerrahpasa Medical Faculty, ISTANBUL, Turkey

**Background**

Although *L.pneumophila* serogroup(sg)1 is the common disease causing serogroup, rare serogroups can also cause legionellosis.

**Objectives**

We aim to present six cases of legionellosis, of which four cases presented as Pontiac fever and the other two cases presented as Legionnaires' disease. And then emphasize the regional epidemic and pandemic threats of infectious diseases that are transmitted between neighboring countries.

**Methods**

We reported 6 cases of legionellosis caused by rare sg of *L. pneumophila*. Their diagnosis was supported with clinical, Radiological and serological findings and serogrouping *L. pneumophila*. The analyses of IgG and IgM were performed in our unit using the Anti-Legionella Pneumophila Indirect Immunofluoresan IgM, IgG kit (Euroimmun AG, Leubeck, Germany). All six serum samples sent, Euroimmun AG Clinical Immunology Laboratory in Lubeck, Germany for serogrouping.

**Conclusions**

Two of them were diagnosed with Legionnaires' disease caused by *L.pneumophila* sg12 (index case KY ) and sg11 (his wife ZY ) and 4 of the cases

were diagnosed with Pontiac fever caused by *L.pneumophila* sg14 (ZY), sg4(AK), sg4 with sg6 (BT) whereas the sg of *L.pneumophila* detected in ZC could not be identified. This study reemphasized that not only *L. pneumophila* serogroup 1, but other rare serogroups might cause also legionellosis which may increase in frequency and cause regional epidemics. It should be noted that these epidemics can also become a threat and a severe public health problem for all countries. Global-scale solutions should be developed for epidemics that could threaten this region

<sup>2</sup>*Medical Pathology, Istanbul University Cerrahpasa Medical Faculty, ISTANBUL, Turkey*

<sup>3</sup>*Gastroenterology, Istanbul University Cerrahpasa Medical Faculty, ISTANBUL, Turkey*

**Background**

Geographical variation in the frequency of various gastroduodenal pathologies was shown to be related to the geographical diversity of H.pylori cagA/EPIYA patterns.

**Objectives**

We sought to determine the EPIYA patterns of cagA-positive H.pylori strains isolated from patients with different endoscopic diagnoses and from patients with gastric cancer (GC) who lived in Istanbul and surroundings areas, a Western region of Turkey located both in Europe and Asia.

.

**Methods**

One hundred and fifty-eight cagA-positive strains were included in the study; 84 were isolated from patients with gastritis (G), 38 were from patients with GC, 22 were from patients with duodenal ulcers (DU) and 14 were from patients diagnosed endoscopically with having normal gastrointestinal systems (NGIS). Specific primers were used for the detection of EPIYA patterns and representative bands were also confirmed by DNA sequencing.

**Conclusions**

EPIYA A, B, C or D were found in 142 of the 158 strains (89.9%). EPIYA-ABC was detected in 83 H. pylori 50 (59.5%) were isolated from patients with G, 14 (63.7%) were isolated from patients with DU, 9 (23.7%) were isolated from patients with GC and 10 (71.4%) were isolated from patients with NGIS. EPIYA-C with  $\geq 2$  repeats was detected in 34 (21.5%) cagA-positive H.pylori cases and 22(64.7%) of these cases involved GC. The most common EPIYA pattern isolated from cases with different endoscopic diagnoses was the Western type EPIYA-C. EPIYA-C with  $\geq 2$  repeats was

found to be more common in cases with GC; in other cases with different endoscopic diagnoses, EPIYA-C with one repeat was the most frequent.

**IDENTIFICATION AND CHARACTERIZATION OF STRESS FIBER INDUCING EFFECTOR PROTEIN OF VIBRIO PARAHAEMOLYTICUS T3SS2**

H. Hiyoshi<sup>1</sup>, R. Okada<sup>1</sup>, S. Matsuda<sup>1</sup>, K. Gotoh<sup>1</sup>, Y. Akeda<sup>1</sup>, T. Iida<sup>1</sup>, T. Kodama<sup>1</sup>

<sup>1</sup>International Research Center for Infectious Diseases, RIMD Osaka University, Osaka-Suita, Japan

**Background**

*Vibrio parahaemolyticus* is an important pathogen that causes food-borne gastroenteritis in humans. The type III secretion system encoded on chromosome 2 (T3SS2) plays a critical role in the enterotoxic activity of this bacterium. Tissue culture analysis has shown that T3SS2 causes two dramatic changes in the actin cytoskeleton: the accumulation of F-actin beneath bacterial microcolonies and the induction of actin stress fibers. VopV, which is enterotoxic effector, exhibits F-actin binding activity and is responsible for the F-actin accumulation phenotype. However, the mechanisms that underlie T3SS2-dependent actin stress fiber formation and the main effector have not been elucidated.

**Objectives**

The aim of this study is to identify effector protein responsible for T3SS2-dependent stress fiber formation.

**Methods**

*V. parahaemolyticus* strain RIMD2210633 (KP-positive, serotype O3:K6) was used for parent strain. A four-primer polymerase chain reaction (PCR) technique was used to engineer an in-frame deletion mutation. Caco-2 cells were infected with *V. parahaemolyticus* for 3 h at a multiplicity of infection (MOI) of 10. Actin was detected with Alexa Fluor® 488-phalloidin. Cellular and bacterial DNAs were stained with Hoechst 33258.

**Conclusions**

After screening candidate ORFs encoded within the Vp-PAI region, a known pathogenicity island in pathogenic strains, we identified an effector candidate protein involved in stress fiber formation. A deletion of this gene did not affect to T3SS2-dependent enterotoxicity in rabbit ileal loop model, but this mutant caused a dramatic change in actin stress fiber formation, thereby suggesting that this protein is a T3SS2 effector involved in the induction of stress fiber formation.

## **STRUCTURE-FUNCTION ANALYSIS OF THE TYPE 3 SECRETION SYSTEM TRANSLOCATOR IPAB**

N. Kwak<sup>1</sup>, M. Kolbe<sup>1</sup>

<sup>1</sup>*Structural Systems Biology, Max Planck Institute for Infection Biology, Berlin,  
Germany*

### **Background**

The Type 3 Secretion System (T3SS) enables the invasion the human intestinal gut mucosa by *Shigella flexneri*. The T3SS consists of a membrane embedded basal body and an extracellular needle. At the distal end of the needle a tip complex senses and binds the host cell membrane. Upon binding secretion of effectors from the bacterial cytoplasm through the T3SS into the host cell is activated. The secretion of effectors follows a defined order and prior secretion unfolding of the effectors enables the transport through the needle. Early secreted effectors, known as translocators form pores in plasma membranes. The translocators such as the invasion plasmid antigen B (IpaB) are bound to chaperones (IpgC) in the bacterial cytoplasm. For successful infection the IpaB/IpgC complex disassembles and unfolded IpaB is secreted while IpgC remains in the bacterial cytoplasm. Thus, IpaB adopts different folding states before and after secretion which is studied by X-ray crystallography and other biophysical methods.

### **Objectives**

Analysis and comparison of different IpaB conformations with the aim to gain insight into IpaB function.

### **Methods**

Detergents for stabilizing the hydrophobic domains of full length IpaB were used for crystallization trials as well as full length IpaB in complex with IpgC without detergent. In another approach soluble fragments of IpaB were successfully crystallized and the structure determined. IpaB fragments were also cocrystallized with IpgC and the structural determination is in progress.

### **Conclusions**

Based on this study, future design of small inhibitors preventing correct IpaB folding could be beneficial for therapeutic-clinical use against *Shigella* infections.

**MIXED INFECTION ENHANCES THE VIRULENCE OF AEROMONAS IN THE CAENORHABDITIS ELEGANS MODEL**

T. Mosser<sup>1</sup>, E. Talagrand-Reboul<sup>1</sup>, S. Colston<sup>2</sup>, J. Graf<sup>2</sup>, M.J. Figueras<sup>3</sup>, E. Jumas-Bilak<sup>1</sup>, B. Lamy<sup>1</sup>

<sup>1</sup>Équipe Pathogènes Hydriques Santé Environnements UMR 5569 HSM, Université de Montpellier, Montpellier, France

<sup>2</sup>Department of Molecular and Cell Biology, University of Connecticut, Storrs, USA

<sup>3</sup>Unidad de Microbiología Facultad de Medicina y Ciencias de la Salud, Universidad Rovira i Virgili, Reus, Spain

**Background**

*Aeromonas* virulence remains poorly understood, virulence of any given strain being hardly predictable. In addition, *Aeromonas* human infections involve mixed *Aeromonas* isolates (5-10% cases) with an unknown impact on virulence.

**Objectives**

To evaluate virulence of strains recovered from mixed aeromonad infections, alone and in association.

**Methods**

Twelve *Aeromonas* isolates recovered in pairs from 6 mixed infections were tested against the *Caenorhabditis elegans* virulence model. Dead worms were counted each day during 15 days. Median time for killing worms (TD50) was determined for single isolates and for natural and experimental pairs. Experiments were repeated 3 times, independently. Genomes of 7 isolates were sequenced using an Illumina Myseq; virulence-associated genes were sought within the draft genomes.

**Conclusions**

Eight isolates were weak killers (TD50≥7 days) when they were administered alone, two pairs showed an enhanced virulence: the TD50 was significantly lowered from 7.8 and 8.3 days to 3.3 days (couple 76c+77c) and from 6 and 9 days to 4.5 days (couple 25a+25b). Synergy was also observed for 5 of the 14 experimental pairs tested, each including one strain from the natural synergistic couples. Only couples involving strains from distinct species showed synergy. The genome content of virulence-associated genes failed to explain virulence synergy and to identify pathotypes, although some virulence-associated genes present in some strains were absent from the companion strain (e.g., T3SS).

Synergistic virulence observed between infectious *Aeromonas* isolates stresses to consider *Aeromonas* infection process at the community level and not only according to virulence content as in pathotype concept.

**STAPHYLOCOCCUS AUREUS-DERIVED MEMBRANE VESICLES EXACERBATE SKIN INFLAMMATION IN ATOPIC DERMATITIS**

J. LEE<sup>1</sup>, S. JUN<sup>1</sup>, J. LEE<sup>1</sup>, S. KIM<sup>2</sup>, C. CHO<sup>2</sup>, S. KIM<sup>3</sup>

<sup>1</sup>Department of Microbiology, Kyungpook National University School of Medicine, Daegu, Korea

<sup>2</sup>Division of Life Science, Korea Basic Science Institute, Daejeon, Korea

<sup>3</sup>Department of Pharmacology, Kyungpook National University School of Medicine, Daegu, Korea

**Background**

Skin colonization or infection with *Staphylococcus aureus* is known to trigger aggravation of atopic dermatitis (AD). However, the exact mechanisms by which *S. aureus* can worsen AD are unknown.

**Objectives**

We investigated whether and how *S. aureus*-derived membrane vesicles (MVs) contribute to worsening of AD.

**Methods**

HaCaT cells were treated with *S. aureus* MVs and were analyzed for the expression of pro-inflammatory cytokine genes. Immunopathology and cytokine gene profiles were analyzed after topical application of *S. aureus* MVs to AD-like skin lesions in a mouse model.

**Conclusions**

Intact MVs from *S. aureus* delivered their components to keratinocytes and stimulated pro-inflammatory cytokine gene expression. However, MVs with a disrupted membrane neither delivered their components to keratinocytes nor resulted in cytokine gene expression. A knockdown of nucleotide-binding oligomerization domain 2 by using small interfering RNAs completely suppressed IL-8 gene expression. Topical application of *S. aureus* MVs to AD-like skin lesions in the mouse model induced massive infiltration of inflammatory cells and the resulting eczematous dermatitis. This inflammatory reaction was associated with a mixed Th1/Th2 immune response and enhanced expression of chemokine genes in AD-like skin lesions. *S. aureus* MVs delivered effector molecules to host cells and triggered an inflammatory response both *in vitro* and *in vivo*. MVs produced by *S. aureus* colonizing or infecting AD skin lesions may be responsible for worsening of AD. Thus, *S. aureus* MVs are a new therapeutic target for the management of AD aggravation.

<sup>2</sup>Interfaculty Institute for Microbiology and Infection Medicine, University Clinics Tübingen, Tübingen, Germany

<sup>3</sup>Protein Evolution, Max Planck Institute for Developmental Biology, Tübingen, Germany

<sup>4</sup>Department of Microbial Genetics, University of Tübingen, Tübingen, Germany

<sup>5</sup>Electron Microscopy facility, Max Planck Institute for Developmental Biology, Tübingen, Germany

### **Background**

Intimin and Invasin are prototypical inverse (Type Ve) autotransporters and important virulence factors of enteropathogenic *Escherichia coli* and *Yersinia spp.* respectively. In addition to a C-terminal extracellular domain and a  $\beta$ -barrel transmembrane domain, both proteins also contain a short N-terminal periplasmic domain that, in Intimin, includes a lysin motif (LysM), which is thought to mediate binding to peptidoglycan.

### **Objectives**

We investigated the functions of the Intimin periplasmic domain, particularly to study its role in peptidoglycan binding and dimerisation.

### **Methods**

We used pull-down, solid phase binding and in vivo binding assays to demonstrate that the Intimin LysM binds to peptidoglycan. Dimerisation of the periplasmic domain was shown by analytical size exclusion chromatography and in vitro cross linking experiments. We further solved the structure of the Intimin LysM using NMR.

### **Conclusions**

We show that the periplasmic domain of Intimin does bind to peptidoglycan both in vitro and in vivo, but only under acidic conditions. We were able to determine a dissociation constant of 0.8  $\mu$ M for this interaction, whereas the Invasin periplasmic domain, which lacks a LysM, bound only weakly in vitro and failed to bind peptidoglycan in vivo. Furthermore, in contrast to previous reports, we show that the periplasmic domain mediates dimerisation.

We further show that dimerisation and peptidoglycan binding are general features of LysM-containing inverse autotransporters. Peptidoglycan binding by the periplasmic domain in the infection process may aid in resisting mechanical and chemical stress during transit through the gastrointestinal tract.

**BRINE SHRIMP: A HOST MODEL SYSTEM TO STUDY BACTERIAL VIRULENCE AND SYMBIOSIS**

X. LI<sup>1</sup>, M. LEE<sup>1</sup>, S. KIM<sup>1</sup>, J.-H. LEE<sup>1</sup>

<sup>1</sup>department of pharmacy, Pusan National University, Busan, Korea

**Background**

Brine shrimp is an aquatic crustaceans belonging to a genus of *Artemia*. This organism is widely used for testing the toxicity of chemicals and for live food in the larviculture of economically important fishes and crustaceans.

**Objectives**

In this study, a brine shrimp, *Artemia salina* was evaluated for the bacterial infection and symbiotic host model.

**Methods**

Brine shrimp nauplii were incubated in petri dish containing 5 ml of autoclaved artificial seawater. Various numbers of bacterial cells were added to the seawater and incubated at 28°C for several days. The survival of shrimps was daily scored after the addition of the bacteria and the existence of bacteria in shrimp gut was observed by fluorescence microscope.

**Conclusions**

Pathogenic bacteria caused significant death of brine shrimps reflecting their virulence, but some shrimps surviving the infection were found to grow bigger and faster. Both *E. coli* and *P. aeruginosa* could survive in the brine shrimp gut, but *E. coli* was able to survive only for limited period whereas *P. aeruginosa* survived more and longer in the gut than *E. coli*. Furthermore, we found that the pre-infection of avirulent *P. aeruginosa* strain improves the survival of brine shrimp in the challenge of other pathogenic bacteria. These results strongly suggest that survival of *P. aeruginosa* as a symbiont has a beneficial effect on host and brine shrimps may be a valuable artificial model to study symbiosis.

**DIRECT INVOLVEMENT OF CYCLIC AMP (cAMP) AND cAMP RECEPTOR PROTEIN (CRP) IN NATURAL COMPETENCE REGULATOR TFOX EXPRESSION**

R. Wu<sup>1</sup>, M. Zhao<sup>1</sup>, B. Kan<sup>1</sup>, W. Liang<sup>1</sup>

<sup>1</sup>Depart. of Diarrheal Disease,

National Institute for Communicable Disease Control and Prevention China CDC,  
Beijing, China

**Background**

*Vibrios* are normal inhabitants in the estuarine and marine environments, where they exist both as free-living bacteria and in association with phytoplankton, zooplankton, and crustaceans. Chitin-induced competence found in several *Vibrios* represents a newly appreciated mode of horizontal gene transfer in these marine bacteria and undergoes tight regulation. Sxy (also called TfoX) and CRP are two important activator proteins in the competence development. Sxy functions synergistically with CRP to activate the competence genes regulon expression.

**Objectives**

Sxy/TfoX expression has been shown to be regulated by RNA second structure and sRNA *tfoR* at the post-transcriptional level. In this study, we investigated the transcriptional regulation of *tfoX* expression by cAMP-CRP complex.

**Methods**

qRT-PCR and complement assay were used to analyze the *tfoX* mRNA level. Promoter transcriptional fusion and site-directed mutagenesis of the putative CRP-binding sites were applied to determine the *tfoX* promoter activities. EMSA assay was employed to demonstrate the direct binding of CRP to the *tfoX* promoter. The transcriptional start site of *tfoX*<sup>VF</sup> was determined by 5'RACE.

**Conclusions**

CRP positively regulates the *tfoX* expression at the transcriptional level; there are two functional CRP binding-sites on *tfoX*<sup>VC</sup> promoter region and CRP directly binds to the promoter region to initiate its transcription; transcriptional start site of *tfoX*<sup>VF</sup> was mapped at -126 nucleotides upstream of translational start site; similar -10 motifs and putative CRP-binding sites on different species' *tfoX* promoter indicate CRP regulation of *tfoX* is a conserved regulatory mechanism in *Vibrio* species.

## **REGULATION OF THE CYCLIC AMP SIGNALING PATHWAY OF KLEBSIELLA PNEUMONIAE IN TYPE 3 FIMBRIAE EXPRESSION**

C.T. LIN<sup>1</sup>, J.C. Lin<sup>1</sup>

<sup>1</sup>*School of Chinese Medicine, China Medical University, Taichung, Taiwan*

### **Background**

*Klebsiella pneumoniae* (Kp) is the predominant pathogen isolated from liver abscesses of diabetic patients in Asian countries. Although elevated blood glucose levels cause various immune problems, its effects on Kp virulence remains largely unknown. In bacteria, cyclic AMP (cAMP), a well-known second messenger, plays a fundamental role in global gene regulation in response to exogenous glucose levels. However, targets regulated by cAMP signaling pathway remain uncharacterized in Kp.

### **Objectives**

To investigate the role of cAMP signaling pathway in Kp pathogenesis.

### **Methods**

DNA microarray, promoter activity assay, qRT-PCR, western blotting assay, biofilm formation, electrophoresis mobility shift assay

### **Conclusions**

Based on the analysis of DNA microarray results, we noted a serial of type 3 fimbrial genes was apparently increased in  $\Delta crp$  strain. It indicates that CRP could repress the type 3 fimbriae expression. By using promoter activity assay, western blotting, and qRT-PCR to confirm that the MrkA expression, the major pilin of type 3 fimbriae, was regulated by cAMP signaling pathway. However, no typical CRP binding site was found in the sequence of  $P_{mrkA}$ , suggesting CRP regulates the *mrkA* transcription via other mediator(s). According to previous studies, multiple proteins, which include Fur, MrkH, MrkI, MrkJ, and YjcC have been shown to mediate the type 3 fimbriae expression. The underlying mechanism of cAMP signaling pathway and the mediators as described above in regulating the type 3 fimbriae expression was investigated in this study.

## **IDENTIFICATION OF FITNESS DETERMINANTS IN PSEUDOMONAS AERUGINOSA INFECTION**

A. Lorenz<sup>1</sup>, S. Weiß<sup>2</sup>, S. Häußler<sup>1</sup>

<sup>1</sup>Molecular Bacteriology, Helmholtz Centre for Infection Research, Braunschweig, Germany

<sup>2</sup>Molecular Immunology, Helmholtz Centre for Infection Research, Braunschweig, Germany

### **Background**

*Pseudomonas aeruginosa* is a clinically highly relevant opportunistic pathogen known to cause acute and chronic infections. This bacterium can adapt to the host by environmentally driven alterations in gene expression as well as genomic alterations in response to selective pressures by the environment.

### **Objectives**

The aim of this study is to identify genetic adaptations that are key to fitness and successful establishment of acute and chronic infections by *P. aeruginosa*.

### **Methods**

We have developed an *in vivo* model for *P. aeruginosa* biofilm formation in CT26 tumor-bearing mice. This murine model offers the unique opportunity to screen the contribution of individual genes to the fitness of *P. aeruginosa* during *in vivo* biofilm formation. Furthermore, the inclusion of an acute lung infection model allows the comparison of fitness parameters in chronic to acute infections. These parameters will be investigated using (i) a PA14 transposon mutant library (Skurnik *et al.* 2013) as forward genetic approach and (ii) a reverse genetic approach by passaging bacteria in the animal host. To evaluate the contribution of individual genes onto bacterial fitness, isolated bacteria are quantified using high-throughput insertion and whole-genome sequencing, respectively.

All animal experiments were approved by the local regulatory board LAVES (Niedersächsisches Landesamt für Verbraucherschutz und Lebensmittelsicherheit) and the EU Directive 86/609/EEC, OJ L 358, p 1-28; 18.12.1986.

### **Conclusions**

Here we present a dual approach to gain insights into fitness determinants important during *P. aeruginosa* infection in different host environments.

<sup>2</sup>Microbiology Immunology and Infectious Diseases, University of Calgary, Calgary, Canada

<sup>3</sup>Genetic, University of Córdoba, Córdoba, Spain

<sup>4</sup>Animal Health, University of Leon, León, Spain

**Background**

Glasser's disease, caused by *Haemophilus parasuis* (*Hps*), produces annually pig significant economic losses. It is broadly known the relevance of transferrin binding proteins (Tbps) as virulence factor for developing this disease in the host

**Objectives**

Subunit vaccines based on the native, wild-type TbpB and on a mutant TbpB (TbpBY167) (losing its ability for binding porcine transferrin) from *Hps* serovar 5 were designed

**Methods**

Immunization and challenge (with an intratracheal administration of 10<sup>8</sup> CFU/ml of the Nagasaki strain of *Hps* 5) experiment was implemented in colostrum deprived pigs for comparing the protective response developed for wild-type and mutant proteins. Clinical symptoms were monitored after challenge and pathological findings were determined upon necropsy. All the pigs immunized with adjuvant alone and challenged did not survive more than 72 hours. On the other hand, most of the pigs immunized with wild-type TbpB survived the full two weeks after challenge but clinical signs and severe chronic lesions were observed. All the pigs immunized with the mutant also survived until the end of the study, without signs of infection.

Were confirmed the results by indirect ELISA test, by immunohistochemistry and real-time quantitative PCR was used to determine the relative expression of 27 immune-related genes in the lungs of the pigs belonging to experimental groups, at the necropsy time

**Conclusions**

The highest protective response was that afforded by the mutant.

Genes associated with the inflammation are highly overexpressed in the group of only infected animals and this does not happen in the other two experimental groups.

## **GENETIC DIVERSITY OF COLICIN E1 AND FIMBRIAE TYPE I IN ESCHERICHIA COLI STRAINS**

L. Micenkova<sup>1</sup>, K. Pomorská<sup>1</sup>, D. Šmajs<sup>1</sup>

<sup>1</sup>Department of Biology, Masaryk University, Brno, Czech Republic

### **Background**

Uropathogenic *E. coli* (UPEC) strains are causative agents in the majority of human urinary tract infections (UTIs). UPEC strains contain several virulence factors allowing them to colonize human urinary tract (e.g. fimbriae type I). Moreover, higher prevalence of colicin E1 like plasmids and a possible role of colicin E1 protein as a potential important virulence factor of UPEC strains was described in UPEC strains.

### **Objectives**

The main aim of the study focused on the genetic variability of colicin E1 and *fimH* gene (encoding the mannose-sensitive FimH adhesin of fimbriae type I) between human intestinal and extraintestinal *E. coli* strains (UPEC strain).

### **Methods**

In the set of 58 human fecal *E. coli* strains and 55 UPEC strains, *fimH* gene and colicin E1 gene was sequenced and analyzed. All clinical samples were collected after patients gave informed consent. The study was approved by the ethics committee of the Faculty of Medicine, Masaryk University, Brno, CZ.

### **Conclusions**

Two different colicin E1 genetic variants were described. Colicin E1-A genetic variant that prevailed among human fecal *E. coli* had 1566 bp and colicin E1-B genetic variant (prevailed in UPEC strains) had 1569 bp. The main genetic difference identified between these variants encoded colicin receptor domain. A significant increase of the substitution of residue Arg166 - His166 in fimbriae-associated pilin domain of FimH was identified in UPEC strains. It is possible that genetic variability identified in genes encoding colicin E1 and FimH modify virulence of UPEC strains.

<sup>3</sup>Genetics Evolution and Bioagents, University of Campinas, Campinas, Brazil

### Background

*Salmonella enterica* is the causal agent of a widespread and neglected infectious disease in the world, that despite efforts, it lacks completely effective vaccine formulations. The non-typhoidal serovars Typhimurium and Enteritidis are frequently responsible for salmonellosis outbreaks, usually associated with gastrointestinal infections, but they can spread systemically, particularly in immunocompromised patients or those who suffering from malaria. In Africa, non-Typhi *Salmonella* comprises around 50% of reported cases of bacteremia and are associated with nearly 20% of the fatal cases of salmonellosis. It's crucial to test the potential of new mutants and new serovars for use as live attenuated vaccines to contain the disease.

### Objectives

We used recent clinical isolates of *S. Typhimurium* and *S. Enteritidis* to develop the strains LGBM01 $\Delta$ *fis* and SEnPT4 $\Delta$ *fis*, respectively, and evaluated their phenotype under *in vitro* conditions.

### Methods

The phenotypic tests performed included analysis of growth in Luria Broth with measurements taken every hour, motility test on semi-solid agar plates and invasiveness in primary macrophages obtained from BALB/c mice.

### Conclusions

The results showed no significant differences in growth rate in Luria Broth between the mutant strains and the respective wild strain, but the motility in semi-solid agar plates was significantly decreased, at least 50%, in the mutant strains. Interestingly, the ability to invade primary macrophage cells was significantly affected only in the Typhimurium mutant strain. Those results showed an important difference for the role of the same DNA binding protein in these serovars that needs to be considered for future use in vaccine development.

## **PATHOGENIC FEATURES OF BACTERIAL STRAINS ISOLATED FROM SURGICAL RINSE WATER AND MEDICAL INSTRUMENTS**

M. Mitache<sup>1</sup>, M. Popa<sup>2</sup>, I. Gheorghe<sup>2</sup>, A. Cota<sup>3</sup>, V. Lazar<sup>2</sup>, C. Bleotu<sup>2</sup>, M.C. Chifiriuc<sup>2</sup>

<sup>1</sup>preclinic, University of medicine Titul Maiorescu, Bucharest, Romania

<sup>2</sup>Life Environmental and Earth Sciences,

Research Institute of the University of Bucharest, Bucharest, Romania

<sup>3</sup>microbiology, INCDMI Cantacuzino, Bucharest, Romania

### **Background**

One of the potential sources for bacterial contamination in hospital environments is represented by the inadequate manual cleaning of medical instruments.

### **Objectives**

The purpose of this study was to investigate the pathogenic features of microbial strains isolated from sterile water use for rinsing the surgeons hands and surgical medical instruments, in order to establish potential contamination risks for patients.

### **Methods**

A number of 200 water samples and 400 surgical instruments have been processed for routine microbiological analyses, following the existent ISO guidelines. The isolated strains have been identified using miniAPI galleries and investigated for antibiotic susceptibility profiles and for the production of cell-associated (adherence to inert and cellular substratum, biofilm development) and soluble, enzymatic (hemolysins, lecithinase, lipase, caseinase, gelatinase, amylase, esculin hydrolysis, DN-ase) virulence factors, using phenotypic (disk diffusion method, selective media for enzymatic factors production) and PCR-based methods.

### **Conclusions**

Bacteria were isolated in 10% of the analyzed water samples and from 5% of the investigated instruments. The following bacteria were isolated in the frequency decreasing order: *Pseudomonas aeruginosa*, *Brevundimonas* sp., *Micrococcus luteus*, *Staphylococcus haemolyticus*, *S. warneri*, *P. putida*, *P. stutzeri*, *Stenotrophomonas maltophilia*, *Moraxella* sp. Pore-forming toxins and enzymes have been the most frequently produced, followed by caseinase and esculin hydrolysis. The genetic support of these virulence factors has been confirmed by PCR. The analyzed strains exhibited only natural resistance profiles, demonstrating the

environmental origin of the isolated strains. The highest frequency of pseudomonades suggests that biofilm formation within piping is the source of contamination of surgical rinse water.

**UNUSUAL INCREASE OF TYPHOID FEVER CASES IN JAPAN AND  
MOLECULAR EPIDEMIOLOGICAL ANALYSIS OF THE CAUSATIVE AGENT,  
SALMONELLA TYPHI**

M. Morita<sup>1</sup>, H. Izumiya<sup>1</sup>, M. Ohnishi<sup>1</sup>

<sup>1</sup>*Department of Bacteriology I, National Institute of Infectious Diseases, Tokyo, Japan*

**Background**

Typhoid fever is a systemic infection caused by *Salmonella enterica* serovar Typhi and transmitted from human to human via food or drinking water; therefore, hygiene and sanitary conditions mainly determine its spread. As a result of improved public sanitation, most of the cases in Japan have been sporadic and have come from abroad in recent years. In 2013, however, we observed an unusual increase of typhoid fever cases which seemed to be domestic infection.

**Objectives**

In this study, we assessed increase of the typhoid fever patients without histories traveling abroad and examined molecular epidemiological analysis of *S. Typhi*.

**Methods**

A total of 27 typhoid fever cases without histories traveling abroad were identified in 2013 and 26 *S. Typhi* isolates were collected. All isolates were examined with phage type and MLVA.

**Conclusions**

Of the 26 isolates, 15 strains were classified as phage type A or B1 and formed major cluster with 5 types of single locus variants by cluster analysis of the MLVA profiles. It seemed that closely related strains were causative agents of increased typhoid fever cases in Japan, 2013. These 15 patients were reported during 5 months (July to November) peaked at September. They ranged in age from 6 to 83 years (median age 32 years) and the male:female ratio was 1:1.5. Interviews by physicians or public health officers could not reveal specific information which leads to epidemiological link; therefore we have no identifiable source of infection.

Charles University 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic

<sup>2</sup>Laboratory of Genomics and Bioinformatics,

Institute of Molecular Genetics of the ASCR, Prague, Czech Republic

<sup>3</sup>School of Pharmacy and Biochemistry, University of Buenos Aires, Buenos Aires, Argentina

**Background**

*Burkholderia cepacia* complex (Bcc) bacteria pose major threat to cystic fibrosis (CF) patients. Bcc infections can result in untreatable and fatal cepacia syndrome (CS) which is manifested as rapid deterioration of lung functions and septicaemia. The mechanisms behind transition from Bcc chronic infection to CS remain unknown.

**Objectives**

To gain insight into processes involved in development of CS, we compared transcriptomes of a lung isolate (chronic infection) and a bloodstream isolate (CS) from the same patient. Both isolates were of the same sequence type (ST872) and belonged to the Bcc species *B. contaminans* which is predominant among CF infections in Argentina.

**Methods**

Both strains were cultivated in three growth media: sputum (natural habitat of lung isolate), heat-inactivated human serum (natural habitat of bloodstream isolate) and control mineral medium, each in biological triplicates. RNA was extracted in mid-log growth phase, sequenced using RNA-Seq technology (Illumina) and converted to normalized transcript level values.

**Conclusions**

The expression of approximately 1,300 (18%) genes differed more than 3-fold between lung and sputum isolate. The bloodstream isolate showed markedly increased expression of quorum sensing-regulated pathogenicity determinants (motility, extracellular proteases, AidA, lectins, Flp pilus), hypoxia-activated genes and two antifungal compound synthetic clusters (occidiofungin and pyrrolnitrin). Agar plate assays confirmed rapidly increased motility and proteolytic, hemolytic and antifungal activities of bloodstream isolate. Assessing these phenotypes might help to monitor the progress of infections by *B. contaminans*.

This work was funded by grant from Ministry of Health of the Czech Republic NT12405-5.

<sup>3</sup>Department of Molecular Biology and Genetics, Acibadem University School of Medicine, ISTANBUL, Turkey

<sup>4</sup>Department of Molecular Biology and Genetics, Istanbul Technical University, ISTANBUL, Turkey

### **Background**

*H. pylori* is the main cause of chronic gastritis, ulcer and gastric cancer. The balance between the bacterial virulence factors and the host immune response in the infection determines the different clinical outcomes. The association between Th1, Th17, Treg cells and *H. pylori* infection has been identified, but the effect of the nine major *H. pylori* specific virulence factors; *cag A*, *vacA*, *oipA*, *babA*, *hpaA*, *napA*, *dupA*, *ureA*, *ureB* on Th1, Th17 and Treg cells response in *H. pylori* infected patients has not been fully elucidated.

### **Objectives**

To investigate the correlation of the *H. pylori* virulence factors with the manifestations of gastric disease by developing a multiplex-PCR and the relationship between these virulence factors with Th1, Th17 and Treg cells.

### **Methods**

Multiplex and qRT-PCR were carried out to detect the *H.pylori* specific virulence factors and relationship between these virulence factors with T cells.

### **Conclusions**

The multiplex-PCR was developed to rapid characterisation of nine *H. pylori* virulence genes with in a three PCR reactions. Due to the multiplex-PCR results there was no significant difference in prevalence of virulence factors in patients with gastritis and ulcer. However, prevalence of *napA* virulence factor was significantly higher in

patients with ulcer than gastritis. A positive correlation between the *dupA* virulence factor and IFN- $\gamma$  was observed in gastritis patients. Additionally, IL-17 expression was found significantly positively correlated with the *babA* virulence factor in ulcer patients. Furthermore, a novel expert derived model is developed to identify set of factors and rules distinguishing the ulcer patients from gastritis patients.

## **IMPACT AND ROLE OF THE RNA CHAPERONE HFQ IN VIRULENCE GENE REGULATION OF LEGIONELLA PNEUMOPHILA**

G. Oliva<sup>1</sup>, T. Sahr<sup>1</sup>, M. Knoth<sup>1</sup>, C. Buchrieser<sup>1</sup>

<sup>1</sup>*Biologie des Bactéries Intracellulaires, Institut Pasteur and CNRS UMR3525, PARIS, France*

### **Background**

*Legionella pneumophila*, the causative agent of the pneumonia-like Legionnaires' disease, is commonly found in aquatic habitats worldwide where it multiplies within protozoa. To adapt between intra- and extracellular environments, *L. pneumophila* evolved a biphasic lifecycle wherein it alternates between a replicative (non-virulent) and a transmissive (virulent) phase. This switch is governed by a complex regulatory network. Expression of the Host Factor Q protein (Hfq), a hexameric, RNA-binding protein and chaperon of small RNAs (sRNA) is life cycle regulated and implicated in virulence. How Hfq expression is regulated in *L. pneumophila* is not known.

### **Objectives**

Our aim was to understand how the growth-phase dependent expression of Hfq is regulated and whether a newly identified sRNA is implicated

### **Methods**

By Transcriptional Starting Site mapping of the *L. pneumophila* genome, a sRNA that is transcribed antisense to the *hfq* gene and is overlapping its 5'UTR region was identified. Thus, we postulate that this antisense RNA, named *anti-hfq*, might regulate the life cycle dependent expression of Hfq. We constructed and characterized the *L. pneumophila hfq* deletion mutant and *anti-hfq* overexpressing strains *in vitro* and *in vivo*.

### **Conclusions**

Our results show that Hfq expression is growth-phase dependently regulated by this newly identified antisense RNA. Infection assays revealed that Hfq is a virulence factor necessary for efficient replication in amoeba. Overexpression of *anti-hfq* led to a similar virulence phenotype as *hfq* deletion. This suggests an important role of Hfq and *anti-hfq* in virulence and in the regulatory network governing the biphasic life cycle of *L. pneumophila*.

**Bacterial pathogenicity**

**ISOLATION AND CHARACTERIZATION OF OUTER MEMBRANE VESICLES OF THE FISH PATHOGEN *PISCIRICKETTSIA SALMONIS*.**

C. Oliver<sup>1</sup>, K. Valenzuela<sup>2</sup>, R. Sandoval<sup>1</sup>, R. Haro<sup>1</sup>, M. Hernández<sup>1</sup>, R. Garduño<sup>3</sup>, A. Yáñez<sup>1</sup>

<sup>1</sup>*Instituto de Bioquímica y Microbiología Universidad Austral de Chile, Facultad de Ciencias, Valdivia, Chile*

<sup>2</sup>*Department of Microbiology and Immunology Dalhousie University, Department of Microbiology and Immunology Dalhousie University, Halifax Nova Scotia, Canada*

<sup>3</sup>*Canadian Food Inspection Agency Dartmouth Laboratory, Canadian Food Inspection Agency Dartmouth Laboratory, Dartmouth Nova Scotia., Canada*

**Background**

*Piscirickettsia salmonis* is a Gram-negative intracellular bacterium that causes Piscirickettsiosis in salmonids farms in Chile. It was recently reported that *P. salmonis* produces exotoxins that play a role in the pathogenesis. However a delivery system has not yet been identified. Outer membrane vesicles (OMVs) are 10 to 300 nm spherical-bilayer structures discharged from the surface of many Gram-negative bacteria which are able to deliver toxins and virulence factors. However, the production of OMVs by *P. salmonis* has not been described.

**Objectives**

The aim of this study was to investigate if *P. salmonis* is able to produce OMVs and to realize a microscopic characterization of these vesicles.

**Methods**

*P. salmonis* was grown in basal broth supplemented with Cysteine (3.18 mM) and ferric chloride (0.05 mM) at 18°C until early stationary phase. Bacteria were removed by centrifugation (5000 x g, 10 min at 4°C) and the supernatant were filtrated through a 0.22-µm-pore-size filter. Then, vesicles present in the bacterial free supernatant were isolated by ultracentrifugation (125,000 x g, 2h at 4°C) and analyzed by SDS-PAGE. Finally, CHSE-214 cells infected with *P. salmonis* and negative stained OMVs were visualized by TEM.

**Conclusions**

*P. salmonis* is able to produce OMVs. The purified OMVs appeared as spherical vesicles of different sizes between 27.3 and 145.5 nm. SDS-PAGE analysis showed similar protein profile between OMVs and outer membrane extracts. Finally, OMVs were found into *P. salmonis*-containing vacuoles in infected CHSE-214 cells, suggesting that OMVs may contribute to the pathogenesis of *P. salmonis*.

**MULTIPLE COLONIZATION OF *HELICOBACTER PYLORI* IN PATIENTS WITH CHRONIC GASTRITIS OF REGIONS OF HIGH AND LOW RISK OF GASTRIC CANCER IN COLOMBIA**

A. Pazos<sup>1</sup>, L.E. Bravo<sup>2</sup>, J.A. Matta<sup>2</sup>

<sup>1</sup>Biology, University of Nariño, Pasto, Colombia

<sup>2</sup>Department of Pathology, University of Valle, Cali, Colombia

**Background**

Infection with virulent strains of *Helicobacter pylori* is necessary but not enough for the development of gastric cancer (GC) and its precursor lesions. In Nariño-Colombia, there are populations with high prevalence of *H. pylori* infection, but different GC risk. These results suggest different genetic characteristics of the circulating strains with varying degrees of pathogenicity.

**Objectives**

To evaluate multiple colonization of *H. pylori* isolated from patients with chronic gastritis from two populations with contrast in the risk of developing CG: Tumaco, low risk; Túquerres, high risk. Our hypothesis: there is a greater probability of multiple colonization of *H. pylori* in the population at highest risk for GC.

**Methods**

409 adult patients with dyspeptic symptoms were studied, of which gastric mucosa fragments from the antrum and body were used for the histopathological diagnosis, culture and genotyping (*cagA*, *vacA* and PCR-RAPD). 72 individuals were included, in whom *H. pylori* isolates was achieved in the three biopsies of gastric mucosa, (41/203) from Tumaco and (31/206) Tuquerres. Genetic similarity was calculated using the Nei's coefficient.

**Conclusions**

Genetic diversity was higher among isolates from Tuquerres (0.13) than Tumaco (0.07). After adjusting for age, sex and diagnosis, multiple colonization was 1.7 times more frequent in Tuquerres than Tumaco,  $p = 0.05$ . In Túquerres: high risk of gastric cancer, there was more likely to have multiple colonization. Based on the analysis of the results of the PCR - RAPD, we found greater genetic similarity from isolates of *H. pylori* in the population with low risk for developing GC

#### **IDENTIFICATION OF GENES INVOLVED IN VIRULENCE OF PUM505 PLASMID FROM PSEUDOMONAS AERUGINOSA**

*E. Rodríguez-Andrade*<sup>1</sup>, *V. Meza-Carmen*<sup>2</sup>, *R. Ortiz-Alvarado*<sup>3</sup>, *C. Cervantes*<sup>1</sup>,  
*M.I. Ramírez-Díaz*<sup>1</sup>

<sup>1</sup>Laboratorio de Microbiología, Instituto de Investigaciones Químico-Biológicas. UMSNH, Morelia, Mexico

<sup>2</sup>Laboratorio de Biotecnología, Instituto de Investigaciones Químico-Biológicas. UMSNH, Morelia, Mexico

<sup>3</sup>Fac. QFB, UMSNH, Morelia, Mexico

#### **Background**

pUM505 is a conjugative plasmid of 123 kilobases, originally isolated from a clinical strain of *Pseudomonas aeruginosa*. pUM505 possesses a pathogenicity island (PAI) of 78 genes, 64 of them have been found in the chromosomal PAPI-1 and PAPI-2 PAIs of *P. aeruginosa* PA14, a virulent clinical isolate, however it is unknown whether pUM505 is involved in virulence.

#### **Objectives**

The aim of this study is to determine if the plasmid increases the virulence of the *P. aeruginosa* PAO1 standard strain and to identify the genes responsible for this property.

#### **Methods**

Using as models of virulence lettuce leaves and *Dictyostelium discoideum* cultures pUM505 showed increased virulence of the PAO1 strain. To identify genes involved in virulence a gene bank was constructed by digesting the pUM505 plasmid and ligating the fragments to the vector pUCP20. A library of 120 clones was obtained in the Top10 strain of *E. coli* and PAO1 of *P. aeruginosa*. Four clones of this library were found to increase virulence in both *E. coli* and *P. aeruginosa*. The cloned inserts of these transformants was sequenced, and several ORF's of pUM505 were identified. The ORFs 2, 17 and 42 (*hop*) have homologues that have been reported involved in virulence.

#### **Conclusions**

In conclusion, pUM505 plasmid increases the virulence of its hosts due to some ORF's outside the pathogenicity island. The ORF's identified are currently under study.

**Bacterial pathogenicity**

**ANALYSIS OF THE SALMONELLA TYPHIMURIUM SPI-1 TYPE 3 SECRETION  
SYSTEM SORTING PLATFORM**

J. Reinhardt<sup>1</sup>, I. Bernal<sup>1</sup>, M. Kolbe<sup>1</sup>

<sup>1</sup>Cellular Microbiology, Max Planck Institute for Infection Biology, Berlin, Germany

**Background**

Many Gram-negative bacterial pathogens use a type III secretion system (T3SS) to deliver virulence factors into the cytosol of host cells in order to establish and maintain an infection. This system relies on the sequential secretion of first structural and later effector proteins for its correct assembly and function. The hierarchy of substrate secretion has been proposed to be ensured by a cytoplasmic protein complex, called the "sorting platform".

**Objectives**

We aimed to investigate and characterize the Salmonella Typhimurium "sorting platform" and its components, particularly SpaO, with regard to both their structure and function.

**Methods**

The two expression products of the *spaO* gene were analyzed and the gene mutated to investigate the mechanism by which the second, shorter product is generated. The two proteins were analyzed by SDS-PAGE, mass-spectrometry, size-exclusion chromatography and multi-angle light scattering. The SpaO protein was further co-purified with other "sorting platform" components and the ability of the complex to bind T3SS substrates tested by surface plasmon resonance.

**Conclusions**

The gene for the component SpaO gives rise to both the full-length protein (SpaO) and a shorter product SpaO'. SpaO' is produced from an internal translation initiation site and is required for the stability of full-length SpaO. Together these two proteins associate with other "sorting platform" components to form a complex that is capable of binding different T3SS substrates.

<sup>2</sup>MEDICAL MICROBIOLOGY, Qazvin University of Medical Sciences, Qazvin, Iran

<sup>3</sup>Department of Immunology Faculty of Medical Sciences, Tarbiat Modares University, Tehran, Iran

**Background**

Recent studies have been shown that Helicobacter pylori has an effective role in the migration of bone marrow derived mesenchymal stem cells (BMD-MSCs) throw to gastric tissue .

**Objectives**

This study aimed to find the effect of H.pylori on as bacterial microenvironment on BMD-MSCs transforming into cancer stem cells and metastasis of the tumor cells .

**Methods**

BMD-MSCs were followed for evaluation by flow cytometric analysis with the hAbs for positive and negative of surface markers and treated under the osteogenic and adipogenic differentiation medium. BMD-MSCs were co-cultured with H. pylori and Gastric epithelial cell line (AGS). The expressions of MMP-2, MMP-9, p53 and bcl2 were examined by qRT-PCR

**Conclusions**

When mesenchymal stem cells are attracted to chronic H.pylori infection tissue and gastric ulcer for their tissue healing function, they will be trapped under special microenvironment. This study demonstrated that H. pylori increased the anti-apoptosis factor bcl-2 to keep BMD-MSCs alive and lead them to cancer stem cells by changing the regulation of p53. H. pylori increased the metastatic proteins MMP2 and MMP9 that shows the role of H.pylori on metastasis action. Focusing on H.pylori-induced molecular pathogenesis and the impact of microenvironment in gastric progenitor cells or BMD-MSCs will be crucial to identify the molecular targets in tumor initiation and the origin of gastric cancer.

## **A NOVEL, UNSUSPECTED FEATURE OF SALMONELLA ENTERICA SPI-1 BISTABILITY**

M.A. Sánchez-Romero<sup>1</sup>, J. Casadesús<sup>1</sup>

<sup>1</sup>Genetics, University of Seville, Sevilla, Spain

### **Background**

*Salmonella enterica* pathogenicity island 1 (SPI-1) is a gene cluster that encodes a type 3 secretion apparatus and effectors involved in invasion of epithelial cells. A well known trait of SPI-1 is bistable expression, which generates SPI-1 ON and SPI-1 OFF subpopulations. The biological significance of SPI-1 bistability has been addressed by previous, insightful studies. Bistability has been viewed, for instance, as a division of labour involving self-destructive altruism by the SPI-1 OFF subpopulation (Ackermann et al. *Nature* 454, 987-90, 2008). Another study, however, has envisaged that the SPI-1 OFF subpopulation might benefit from inflammation triggered by the SPI-1 subpopulation (Stecher et al. *PLOS Biology* 5:2177-89, 2007). Furthermore, enhanced tolerance to antibiotics has been detected in slow-growing SPI-1 ON cells (Arnoldini et al. *PLOS Biology* e1001928, 2014).

### **Objectives**

In this communication we describe an additional, unsuspected feature of SPI-1 bistability.

### **Methods**

Single-cell analyses, such as flow cytometry and cell sorting were used to study the expression of SPI-1 in *Salmonella enterica* and its ability to invade epithelial cells.

### **Conclusions**

We show that a pure SPI-1 ON population obtained by bacterial cell sorting is non invasive, suggesting that the SPI-1 OFF subpopulation plays an active role in invasion. In support of this view, we also show that the invasion defect associated to unimodal expression of SPI-1 can be suppressed by mutations that permit formation of a SPI-1 OFF subpopulation.

**THE INVOLVEMENT OF STREPTOCOCCUS ANGINOSUS INFECTION AND THE ABERRANT ACTIVATION-INDUCED CYTIDINE DEAMINASE EXPRESSION IN HUMAN ORAL SQUAMOUS CELL CARCINOMA**

M. SASAKI<sup>1</sup>, K. IWASAKI<sup>2</sup>, Y. KODAMA<sup>1</sup>, T. ISHIKAWA<sup>1</sup>, Y. SHIMOYAMA<sup>1</sup>, Y. SUGIYAMA<sup>2</sup>, S. KIMURA<sup>1</sup>

<sup>1</sup>Microbiology, Iwate Medical University, Morioka Iwate, Japan

<sup>2</sup>Reconstructive Oral and Maxillofacial Surgery, Iwate Medical University, Morioka Iwate, Japan

**Background**

*Streptococcus anginosus* infection could be closely related with oral squamous cell carcinoma, although the mechanism underlying carcinogenesis is still unknown. Recent studies suggested that the aberrant expression of activation-induced cytidine deaminase (AID) in the epithelial cells could result in the generation of nucleotide alterations in tumor-related genes and possible malignant transformation of the AID-expressing cells.

**Objectives**

Using surgical tissue samples and cultured epithelial cells, a possible involvement of the aberrant AID expression in oral squamous cell carcinoma and *S. anginosus* infection was assessed.

**Methods**

The tissue specimens were obtained from the 17 patients with oral cancer after giving informed consent. *S. anginosus* infection and the aberrant AID expression were assessed by the species-specific PCR and RT-qPCR, respectively. Further, the aberrant AID expression and NF- $\kappa$ B activation were examined by a dual luciferase assay and RT-qPCR in three epithelial cell lines and the primary human gingival epithelial cells after stimulation with an *S. anginosus* antigen, SAA.

**Conclusions**

Both *S. anginosus* infection and the aberrant AID expressions were frequently observed in the tissue specimens (47% and 41%, respectively), and the infection was significantly correlated with the aberrant AID expression. The stimulation of the cultured cells with SAA could induce the NF- $\kappa$ B activation and aberrant AID expression in all the epithelial cells tested, and the addition of an inhibitor of NF- $\kappa$ B activation abrogated the aberrant AID expression. Thus, *S. anginosus* infection could be closely related with oral squamous cell carcinoma through the induction of the aberrant AID expression by *S. anginosus* antigen(s).

**IDENTIFICATION OF VIRULENCE FACTORS OF CRONOBACTER SPP.**

K. Schauer<sup>1</sup>, T. Laufer<sup>1</sup>, R. Dietrich<sup>1</sup>, A. Lehner<sup>2</sup>, E. Märtlbauer<sup>1</sup>

<sup>1</sup>Lehrstuhl für Milchhygiene, Ludwig-Maximilians-Universität München,  
Oberschleißheim, Germany

<sup>2</sup>Institute for food safety and hygiene, University of Zürich, Zürich, Switzerland

**Background**

*Cronobacter spp.* are Gram-negative, motile, non-sporeforming, facultative anaerobic bacteria that have been implicated in rare but severe cases of illnesses predominantly in premature and newborn infants. These organisms have been isolated from a wide range of environments, including humans, different animals as well as (raw and processed) food and food production facilities.

**Objectives**

Although progress has been made during the last years, there is still a lack of knowledge on the virulence-associated factors and processes involved during pathogenesis.

**Methods**

To survey the pathogenesis of *Cronobacter*, a *C. sakazakii* ES5 transposon mutant library was screened in several cell lines for genes that are involved in to adhesion to and invasion into host cells as well as subsequent intracellular survival.

**Conclusions**

The majority of attenuated mutants carried insertions in genes involved in energy production and conservation, cell membrane biogenesis, biofilm formation, motility and metabolism. Several selected genes are being functionally analyzed such as genes for flagellar biosynthesis. Preliminary analyses showed that *C. sakazakii* flagella are necessary for adherence and efficient invasion of host cells. Using a specific monoclonal antibody against a living strain of *C. turicensis* 3032, flagellar motility could be inhibited and the ability to invade Caco-2 cells was reduced. Therefore, we present evidence that *Cronobacter* flagella play a crucial role in colonization of host cells.

**TRANSCRIPTOME ANALYSES TO UNDERSTAND INFECTION MECHANISM OF BURKHOLDERIA GLUMAE IN TWO DIFFERENT INFECTION SITES OF RICE**

J. Park<sup>1</sup>, H. Lee<sup>1</sup>, T. Nguyen<sup>1</sup>, J. Kim<sup>1</sup>, M. Yun<sup>1</sup>, I. Park<sup>1</sup>, Y. Seo<sup>1</sup>

<sup>1</sup>Microbiology, Pusan National University, Busan, Korea

**Background**

*Burkholderia glumae* is a causal agent in grain and sheath rot, leading to severe damages in many rice-growing countries under the favorable conditions such as high temperature and humidity. However, its molecular mechanisms are not yet fully understood. For understating of infection mechanism, we analyzed *B. glumae* transcriptome from different infected rice tissues.

**Objectives**

We investigated molecular and physiological changes of *B. glumae* through comparative analyses of differentially expressed genes (DEGs) between in infected grains and in stems.

**Methods**

To gain a genome-wide gene expression profiling, we compared *B. glumae* transcriptome in stem and grain infection sites using the RNA sequencing. We then performed KEGG pathway and module enrichment of differentially expressed genes.

**Conclusions**

Most enriched metabolic and signaling pathways of *B. glumae* in infected stem tissues were bacterial chemotaxis-mediated motility, ascorbate metabolism, and sugar transporters including arabinose and xylose. However, we have confirmed different expression levels of genes involved in those pathways from the infected grains. For example, genes involved in flagellar assembly pathway were strongly down-regulated compared to those of stem tissues. Starch metabolisms were found to be highly enriched in infected grain tissues. Our study provides *in vivo* transcriptional profiling of *B. glumae* in two different tissues. Additionally, comparative analysis of *B. glumae* transcriptome obtained from the stem and grain will give clues on common and unique infection mechanisms in different tissues.

**PREVALENCE OF COLIBACTIN GENES IN ESCHERICHIA COLI RECOVERED FROM URINARY TRACT INFECTION FROM PATIENT WITH GYNECOLOGICAL CANCER**

P.V. Silva<sup>1</sup>, M.S. Capett<sup>1</sup>, K.C.F.A. Silva<sup>1</sup>, M. Calomino<sup>1</sup>, G.R. Paula<sup>1</sup>, L.A. Teixeira<sup>1</sup>

<sup>1</sup>Department of Pharmaceutical Technology, Universidade Federal Fluminense, Niterói, Brazil

**Background**

Patients with gynecological cancer have increased risk for urinary tract infection (UTI) in which *Escherichia coli* is the main bacteria. The rates of antimicrobial resistance are increasing among these bacteria. Moreover, *E. coli* exhibits multiple accessory traits, including yersiniabactin. This virulence factor is associated with a peptide-polyketide compound, colibactin. This genotoxin, which damages DNA in eukaryotic cells, is related to the formation of colorectal cancer. However, little is known about colibactin production ratio in *E. coli* and its relation with antimicrobial resistance.

**Objectives**

To assess the prevalence of yersiniabactin and colibactin genes in a culture collection of *E. coli* isolated from patients with gynecological cancer with UTI and its relation with antibiotic resistance profile.

**Methods**

Two hundred eighteen *E. coli* UTI isolates were analyzed by PCR for detecting the phylogenetic group, *fyuA*, *clbB* and *clbN* genes. The isolate's antibiotic resistance profile was performed previously. Statistical analysis was performed using Fisher's test.

**Conclusions**

Virulence genes *clbB* and *clbN* were detected in 14.7% (32/218) of *E. coli* isolates. All strains in which these genes were detected belonged to the phylogenetic group B2 and had *fyuA* gene. Interestingly, multidrug resistance, defined as resistance to three or more antibiotic classes, showed to be a negative factor for the presence of colibactin production-related genes ( $p=0.0008$ ). Colibactin genes were not detected in aminoglycosides, gentamicin and tobramycin, resistant strains ( $p=0.05$ ) neither in fluoroquinolones, ciprofloxacin and norfloxacin, resistant strains ( $p<0.0001$ ). Finally, 50.8% (32/63) of fluoroquinolone-sensitive strains belonging to the phylogenetic group B2 were positive for *clb* genes ( $p<0.0001$ ).

## **MORAXELLA CATARRHALIS TARGETS HOST COLLAGENS FOR ADHERENCE**

B. Singh<sup>1</sup>, O. Mukherjee<sup>1</sup>, M. Mörgelin<sup>2</sup>, K. Riesbeck<sup>1</sup>

<sup>1</sup>Laboratory Medicine, Klinisk Mikrobiology, Malmö, Sweden

<sup>2</sup>Department of Clinical Sciences Lund University,  
Section of Clinical and Experimental Infectious Medicine, Lund, Sweden

### **Background**

*Moraxella catarrhalis* is a human respiratory pathogen that causes acute otitis media in children and is a common cause of exacerbations in patients with chronic obstructive pulmonary disease. The first step for *M. catarrhalis* colonization is adherence to host tissues that is achieved by interaction with host extracellular matrix (ECM) proteins.

### **Objectives**

Characterization of the interaction between *M. catarrhalis* with host collagens present in respiratory system.

### **Methods**

Collagen I – VI were analysed for their interaction with *M. catarrhalis* clinical isolates by using ELISA and a radioactive direct binding assay. Collagen binding capacity of *M. catarrhalis* was also verified by coating collagens on the glass surface, followed by subsequent bacterial binding and detection by Gram staining. Molecular interaction between different human tissues/collagens and bacterial proteins were performed by EM.

### **Conclusions**

Ubiquitous surface protein (Usp) A2 and UspA2 hybrid (UspA2H) of *M. catarrhalis* were identified as major collagen interacting proteins. The mutants of UspA2 and UspA2H exhibited defective collagen interaction and did not recognize collagen coated on glass surface. All clinical isolates showed binding capacity to fibrillar collagens type I, II and III, and network forming collagen IV and VI. Only 20% clinical isolates showed collagen IV binding capacity. Our data suggests that UspA2/A2H based interaction to collagens could be critical for adhesion of *M. catarrhalis* to host tissues and plays an important role in pathogenesis.

## **PLASMID ENCODED VIRULENCE TRAITS IN CRONOBACTER SAKAZAKII**

N. SINGH<sup>1</sup>, M. Raghav<sup>1</sup>, G. Goel<sup>1</sup>

<sup>1</sup>BIOTECHNOLOGY, JAYPEE UNIVERSITY OF INFORMATION TECHNOLOGY,  
Shimla, India

### **Background**

*Cronobacter* spp. are opportunistic pathogens that cause severe infantile meningitis, septicemia, or necrotizing enterocolitis. Contaminated powdered infant formula has been implicated as the source of this pathogen in most cases, but questions still remain regarding the likely habitat and virulence potential for this strain.

### **Objectives**

The motive of this study was to determine the occurrence of putative plasmid-harbouring virulence traits in *C. sakazakii*.

### **Methods**

The isolation was done as per ISO 22964:2006 on chromogenic media followed by further confirmation by phenotypic and genotypic characterization. Two putative virulence genes *Cronobacter* plasminogen activator (*cpa*) and ferric-iron transporter *eitABCD* gene (*eitA*) were detected by PCR. The *cpa* gene is reported to provide serum resistance to *C. sakazakii* whereas *eitA* gene is generally associated with iron uptake mechanism especially from breast milk and infant formula by *Cronobacter* spp. which may enhance its spread and invasion in a host.

### **Conclusions**

In our investigation, 15 *C. sakazakii* isolates were identified from 154 food and environmental samples based on phenotypic and genotypic characterization. PCR screening using *eitA*-specific primers revealed that the majority (67%) of the *C. sakazakii* isolates harbor the *eitA* gene while in contrast only 27% of the isolates were positive for the gene *cpa*. Taken together, these properties may contribute to the systemic survival of *C. sakazakii* and subsequent invasion of the central nervous system to cause disease. The current study clearly indicates that foods of plant origin are one of the most possible natural reservoirs of this pathogen and also provide important insight into this virulence plasmid from an emerging pathogen

**INHIBITION OF THE LYTIC ACTIVITY OF THE ALTERNATIVE AND CLASSICAL COMPLEMENT PATHWAYS BY A SURFACE LEPTOSPIRAL ADHESIN OF LEPTOSPIRA INTERROGANS**

G. Siqueira<sup>1</sup>, M.V. Atzingen<sup>1</sup>, Z.M. Morais<sup>2</sup>, S.A. Vasconcellos<sup>2</sup>, A.L.T.O. Nascimento<sup>1</sup>

<sup>1</sup>*Centro de Biotecnologia, Instituto Butantan, São Paulo, Brazil*

<sup>2</sup>*Faculdade de Medicina Veterinária, Universidade de São Paulo, São Paulo, Brazil*

**Background**

Pathogenic *Leptospira* are the etiological agent of leptospirosis, a disease of human and veterinary concern. The ability of pathogenic leptospires to survive the bactericidal activity of human sera was demonstrated. Recently, it has been shown that leptospires acquire soluble regulators to evade the immune system.

**Objectives**

To assess the effect of the leptospiral adhesin Lsa23 on the activity of complement system.

**Methods**

The gene LIC11360 was cloned and the protein Lsa23 expressed in *Escherichia coli*. The effect of Lsa23 on classical pathway of complement was assessed by hemolytic assay using antibody-coated sheep erythrocytes, while the effect on alternative pathway was evaluated measuring the deposition of C5b9 on zymosan in presence of MgEGTA buffer. Interaction with factor H (FH), C4BP and plasminogen was evaluated by ELISA. Cofactor activity of complement regulators and proteolytic activity of plasmin were assessed by immunoblotting.

**Conclusions**

Lsa23 was expressed and purified successfully, as visualized by SDS-PAGE. It has been able to inhibit classical pathway-mediated hemolysis by 83%, and also blocked the alternative pathway reducing C5b-9 deposition by 90%. The interaction of Lsa23 with soluble C4BP, FH and plasminogen was dose-dependent. Competition assays suggest these components have distinct binding sites on Lsa23. C4BP and FH preserved their cofactor activity for factor I when bound to Lsa23, as demonstrated by cleavage of C4b and C3b, respectively. Plasminogen bound to Lsa23 could be converted into plasmin and degraded C3b and C4b. Thus Lsa23, a surface receptor for human plasma components, prevents the lytic activity of complement system and could contribute to leptospiral immune evasion process.

**THE VIRULENCE EFFECT ON A HIGHLY CONSERVED REGION OF GENES RESPONSIBLE FOR CAPSULAR POLYSACCHARIDE SYNTHESIS IN KLEBSIELLA PNEUMONIAE**

L. Siu<sup>1</sup>, F. Chen<sup>2</sup>, F. Chang<sup>2</sup>

<sup>1</sup>National Institute of Infectious Diseases and Vaccinology,  
National Health Research Institutes, Taipei, Taiwan

<sup>2</sup>Division of Infectious Diseases and Tropical Medicine Department of Internal Medicine,  
National Defense Medical Center, Taipei, Taiwan

**Background**

Capsular polysaccharides (CPS) are one of the major virulent determinant in *Klebsiella pneumoniae* (KP). Among different serotype of KP, CPS gene cluster could be distinguished into two regions, a conserved and a hyper-variable region.

**Objectives**

Virulence's study by genes' knockout, phagocytosis, serum resistance and mice lethality on highly conserved region of genes in CPS cluster was performed.

**Methods**

Serotype K20 KP was selected. Six genes including *galF*, *acidPPc*, *wzi*, *wza*, *wzb* or *wzc* in CPS conserved region were knocked out and assessed their effect on virulence. In comparing to parental K20 isolate, mutants showed a varied decline in mice lethality (LD<sub>50</sub>) from 10 fold to > 10<sup>5</sup> fold and could be categorized into low (L), moderator (M), and High (H) effect on virulence. For polycistronic mRNAs driven by P1 promoter consisted *galF* and *acidPPc*, low effect on serum resistance and anti-phagocytosis was observed. Only 10 fold of decreasing in mice lethality was achieved in the *DgalF* and *DacidPPc* mutants. For the rest of *wzi*, *wza*, *Dwzb* or *Dwzc* that were driven by P2 promoter, disruption of capsule surface assembly, *Dwzi*, had moderate effect with reduced mice lethality for 100 fold. The deletion of genes, *Dwza*, *Dwzb* or *Dwzc* which were involved in CPS polymerization, caused a significant decrease on virulence (LD<sub>50</sub> >10<sup>7</sup>) and became phagocytic susceptible indicating the importance of these genes in synthesis of capsule.

**Conclusions**

Although conserved genes in CPS cluster were all involved in KP-CPS synthesis, they contributed differently in virulence.

**FEMS-0834**

**Bacterial pathogenicity**

**UNRAVELING THE FUNCTION OF A LEE-ENCODED ORF: ESCK (ORF4) IS A STRUCTURAL COMPONENT OF THE TYPE III SECRETION SYSTEM OF ENTEROPATHOGENIC ESCHERICHIA COLI**

J. Soto<sup>1</sup>, K. Mojica<sup>1</sup>, M. Díaz<sup>1</sup>, N. Espinosa<sup>1</sup>, B. González-Pedrajo<sup>1</sup>

<sup>1</sup>Department of Molecular Genetics., Universidad Nacional Autonoma de Mexico, Mexico City, Mexico

**Background**

The type III secretion system (T3SS) is a molecular device employed by many pathogenic bacteria to translocate a set of proteins, called effectors, directly into the cytoplasm of eukaryotic cells in order to manipulate normal cellular processes to the benefit of the bacterium.

Enteropathogenic *Escherichia coli* (EPEC), an important causative agent of infant diarrhea, relies on a T3SS to deliver effectors into intestinal enterocytes allowing it to colonize the host gastrointestinal tract. Structural components assembling this biological machinery are encoded on a chromosomal pathogenicity island named the *locus of enterocyte effacement* (LEE).

Although the vast majority of LEE-encoded proteins have an assigned function, there are still few of them uncharacterized. One such example is the protein encoded by the *escK* gene (formerly *orf4*).

**Objectives**

To elucidate the role of the LEE-encoded protein EscK in T3SS biogenesis and function.

**Methods**

An EPEC  $\Delta$ *escK* null mutant was generated to assess its type III secretion phenotype. An extensive search of EscK protein-protein interactions with components of EPEC T3SS was performed using the yeast two-hybrid system. Novel protein interactions were corroborated by pull-down experiments. Bacterial fractionation experiments and site directed mutagenesis were carried out in order to dissect the molecular function of this protein.

**Conclusions**

EscK is a critical component of the EPEC T3SS, it is localized to the inner membrane and its localization does not depend on other T3SS components. EscK interacts directly with the C-ring/sorting platform component EscQ. Essential residues for EscK function were identified.

## **IRON UPTAKE SYSTEMS AMONG ESCHERICHIA COLI ISOLATED FROM SKIN AND SOFT-TISSUE INFECTIONS**

*L. Predojevic*<sup>1</sup>, *D. Zgur-Bertok*<sup>1</sup>, *M. Starcic Erjavec*<sup>1</sup>

<sup>1</sup>*Department of Biology, University of Ljubljana - Biotechnical Faculty, Ljubljana, Slovenia*

### **Background**

*Escherichia coli* is a commensal bacterium that can be found in the intestinal microbiota. However, pathogenic *E. coli* strains that are associated with numerous infections, possess virulence factor (VF) genes. *E. coli* is known to be an important cause of skin and soft-tissue infections (SSTI) as it is the 3<sup>rd</sup> most prevalent isolated species from SSTI nevertheless, *E. coli* from such infections are rarely investigated.

### **Objectives**

The main goal of our research was to shed more light on certain iron uptake systems among SSTI *E. coli* strains. We determined their prevalence and analysed possible correlations between their genes and phylogenetic groups and some other VFs as well as bacteriocin genes.

### **Methods**

A collection of 102 previously described SSTI *E. coli* strains was used. The methods employed were cultivation in LB medium, preparation of lysates, and polymerase chain reaction (PCR) with primers specific for the investigated target genes (*fyuA*, *iroCD*, *iucD*, *iha*, *ireA*, *picU* and *hbp*). The PCR products were detected and visualised with agarose gel electrophoresis. All results were statistically processed using Fischer's exact test and Bonferroni correction.

### **Conclusions**

The prevalence of iron up-take systems among the studied collection was 76%, 60%, 47%, 30%, 19%, 10% and 5% for *fyuA*, *iroCD*, *iucD*, *iha*, *ireA*, *picU* and *hbp*, respectively. The following correlations were observed: *fyuA* with B2 phylogenetic group and *cnf1*, *hlyA*, *kpsMTII*, *ompT* and *usp* genes; *hbp* with *ompT*<sub>APEC</sub> and microcin V; *ireA* with *papGII*; *iha* with *papGII* and *iucD*; and *iroCD* with microcinH and *sfa*.

## **MECHANISMS OF NEWBORN BRUCELLA ABORTUS INTERNALIZATION IN CULTURED HOST CELLS.**

J.F. Sternon<sup>1</sup>, M. Van der Henst<sup>1</sup>, X. De Bolle<sup>1</sup>

<sup>1</sup>URBM, UNamur, Namur, Belgium

### **Background**

Bacteria from the *Brucella* genus are gram negative intracellular pathogens responsible for Brucellosis, one of the most widespread anthro-po-zoonosis worldwide. *Brucella* spp. are intracellular pathogens and despite their tremendous impact on world health and economics no human vaccine is currently available and little is known about molecular mechanisms underlying the infection process.

*Brucella* infection of cultured host cells (*i.e.* HeLa cells and RAW 264.7 macrophages) is biphasic. It is first characterized by a « lag phase » consisting in a very low but constant number of colony-forming units during the first hours of infection, and followed by a second « duplication phase » during which bacteria proliferate massively. This defines adhesion/invasion of host cells as a critical step for successful infection.

Recent data showed that infection is mainly carried out by a bacterial subpopulation composed of newly generated bacteria called « newborns », characterized by a single genome copy (Deghelt, Mullier *et al.* 2014)

### **Objectives**

Identification of bacterial components mediating preferential adhesion to and/or invasion of cultured host cells by newborn *Brucella*.

### **Methods**

'With *a priori*' gene deletion, 'without *a priori*' transpositional mutagenesis screen (Tn-seq), lectin staining.

### **Conclusions**

So far, three adhesins (BmaC, BtaE, BtaF) have been shown not to act in the newborn selection when infecting HeLa cells and RAW 264.7 macrophages. Tn-seq is still ongoing. We have detected specific binding of the wheat germ agglutinin to the new pole of *B. abortus* when grown until stationary phase in rich medium.

**INTERACTION WITH VITRONECTIN, LAMININ AND FIBRONECTIN: A NOVEL  
ROLE OF *Haemophilus influenzae* LIPOPROTEIN P4 IN SERUM RESISTANCE  
AND ADHERENCE TO PULMONARY EPITHELIAL CELLS**

Y.-C. Su<sup>1</sup>, O. Murkejee<sup>1</sup>, D. Hood<sup>2</sup>, B. Singh<sup>1</sup>, K. Riesbeck<sup>1</sup>

<sup>1</sup>*Lund University, Klinisk Mikrobiologi, Malmö, Sweden*

<sup>2</sup>*Mammalian Genetics Unit, MRC Harwell, Harwell Science & Innovation Campus,  
Oxfordshire. United Kingdom*

Background Nontypeable *Haemophilus influenzae* (NTHi) is a human-specific Gram-negative species that primarily colonizes the nasopharyngeal and respiratory tract. Interaction with extracellular matrix (ECM) proteins is one of the colonization strategies described for NTHi, and involves several bacterial adhesins.

Objective We describe herein the identification and functionality characterization of a NTHi multifunctional ECM protein receptor.

Methods Outer membrane proteomic analysis revealed that *Haemophilus* outer membrane protein 4 (P4; an acid phosphatase involved in the uptake of nicotinamide adenine dinucleotide) interacted with multiple ECM proteins including vitronectin, laminin and fibronectin. This was further validated when an NTHi 3655 mutant devoid of P4 (NTHi3655 $\Delta$ hel) significantly lost binding to the ECM proteins. Binding was restored by a hel gene trans-complemented mutant. Analyses of protein-protein interactions by ELISA revealed that purified recombinant P4 has a high binding affinity for laminin (dissociation constant,  $K_D=9.26$  nM) and fibronectin ( $K_D=10.19$  nM), but slightly less to vitronectin ( $K_D=16.51$  nM). Interestingly, binding to the ECM proteins was optimal with dimeric P4, a structure that is dependent on the  $\alpha$ -domain. Vitronectin acquisition conferred serum resistance to both P4-expressing NTHi 3655 and *Escherichia coli* transformants, but not to the P4-deficient strains. Importantly, NTHi3655 $\Delta$ hel also displayed decreased adherence to both type II alveolar epithelial and pharynx epithelial cells, and blocking with antibodies suggested the P4-mediated cell adherence was mainly attributed to fibronectin.

Conclusions In conclusion, our data provides new insight into the potential role of P4 as a multiple ECM protein receptor important for colonization and establishment of NTHi infection.

**PASTEURELLA PNEUMOTROPICA SEPTICEMIA IN AN ELDERLY WOMAN**

B. Suh<sup>1</sup>, C. Godshall<sup>1</sup>

<sup>1</sup>*Infectious Diseases, Temple University School of Medicine, Philadelphia, USA*

**Background**

*Pasteurella penumotropica* (PP) is a small gram (-) cccobacillus which is a normal inhabitant of the oropharynx of small animals. Human infections due to PP rarely occur. We saw an elderly woman with septicemia due to PP, and describe herein .

**Objectives**

Human infections due to PP are rarely seen, and it is our intention to share the case experience with others.

**Methods**

A 76 yo woman with comorbidities including ESRD on hemodialysis, DM, CVA, and hypertension was admitted for evaluation of fever, chills, sore throat and fatigue. She also complained of increased cough with yellowish sputum production. She denied myalgia, arthralgia, and dyspnea. She owns a dog. On exam. temp., 38.9C, RR, 23/min, and PR, 112/min. Other positive findings were: erythematous pharynx without exudate, lung auscultation showed diffuse bilateral rhonchi. Lab. findings: leukocytes, WBC at 31.7K/cmm; BUN 43 mg/dl; and Cr 8.69 mg/dl. Sputum culture grew normal oral flora. Blood cultures (B/C) obtained on admission revealed positive (4/4) for small gram-negative coccobacilli which was confirmed to be PP. Antibiotic susceptibility testing: sensitive to penicillin containing preparations (i.e., ampicillin, amoxicillin/clavulanate), doxycycline, TPM/SMX, and moxifloxacin, while resistant to ceftriaxone and azithromycin. She was initially begun on amp./sulb. and she became afebrile and abacteremic on day 3. She remained abacteremic afterward and was discharged on amox/clav 875 mg po BID to complete a 2-wk course.

**Conclusions**

A patient with no known history of definite animal bite or scratch developed PP septicemia and she responded to penicillin preparation nicely without further complication.

**STUDY OF THE AVIAN SALMONELLA CONTRIBUTION TO HUMAN  
SALMONELLOSIS IN CHAD: EXAMPLE OF THE CAPITAL, N'DJAMENA**

D. TABO<sup>1</sup>

<sup>1</sup>*Biology, University of Chad, N'Djamena, Chad*

**Background**

*Salmonella* infection is a major health concern and continues to have a serious economic impact worldwide. It is estimated that *Salmonella* serotypes cause 93.8 million human infections and 155,000 deaths annually through the world.

**Objectives**

The main objective of this study was to update the prevalence and antimicrobial resistance characteristics of *Salmonella* isolated from poultry and from humans experiencing gastroenteritis in N'Djamena and also to evaluate the phylogenetic relationships and to find epidemiological links between human and avian strains isolated in the same period of time and in the same region.

**Methods**

All samples (droppings, sterile Cloths, food and water) collected were analysed according to French Norm for *Salmonella* Spp. NF ISO 6579/2002.

A total of *Salmonella* isolates found in humans and poultry in this study were characterised by ERIC-PCR and IS200-PCR. The PCR analysis was followed by macrorestriction analysis (PFGE).

**Conclusions**

Diagnostic methods carried out during this study led to the isolation of one hundred and twenty seven *Salmonella* strains, belonging to forty two different serotypes. *Salmonella* Colindale was the most prevalent serovar (13.6 %), followed by *Salmonella* Minnesota (10.8 %), *Salmonella* Stanleyville (5.8 %).

PCR results demonstrated that, in the context of this epidemiological study, ERIC- and IS200-PCR methods can be used effectively to limit the number of isolates that have to be serotyped. The comparison of ERIC-PCR, IS200-PCR, PFGE and antimicrobial susceptibility profiles among isolates from human and avian origins has highlighted, the indirect evidence of human contamination sources by *Salmonella* serovars from poultry farms.

**QUANTIFICATION OF LIPOTEICHOIC ACID (LTA) IN ROOT CANALS WITH NECROTIC PULP SUBJECTED TO ENDODONTIC TREATMENT**

C.A. Talge Carvalho<sup>1</sup>, R. Soares de Santana<sup>1</sup>, F. Eduardo de Oliveira<sup>2</sup>,  
M. Cardoso Severo Pereira<sup>2</sup>, M. Carneiro Valera<sup>1</sup>, M. Vieira Pereira Leão<sup>2</sup>,  
A. Olavo Cardoso Jorge<sup>2</sup>, L. Dias de Oliveira<sup>2</sup>

<sup>1</sup>Restorative Dentistry, Univ Estadual Paulista UNESP, São José dos Campos, Brazil

<sup>2</sup>Biosciences and Oral Diagnosis, Univ Estadual Paulista UNESP,  
São José dos Campos, Brazil

**Background**

Gram-positive bacteria release lipoteichoic acid (LTA) as an important virulence factor, which is structurally and immunologically similar to lipopolysaccharide (LPS). The knowledge about LTA actions *in vivo* remains unclear, as well as their participation in the etiology of pulp and periapical diseases, with no reported studies on the quantification of LTA in root canals.

**Objectives**

a) quantifying the levels of LTA in primary infections of root canals with necrotic pulp and apical periodontitis; b) verifying the effects of biomechanical preparation using sodium hypochlorite 2.5% in LTA reduction in root canals.

**Methods**

Ten single-rooted teeth of patients needing endodontic treatment were prepared with Reciproc rotation system and irrigated with 2.5% NaOCl. Root canals samples were obtained immediately after coronary opening (S1) and after biomechanical preparation (S2). LTA quantification was performed by enzyme immunoassay (ELISA), with specific anti-LTA antibodies. The optical density values were converted to µg/mL and analyzed by Student's t test (significance level of 5%).

**Conclusions**

Results: All root canals showed LTA in the collection S1 with an average of  $119.4 \pm 73.2$  µg/mL. After instrumentation, it was observed a reduction in the levels of LTA, with an average in the collection S2:  $77.6 \pm 22.4$  µg/mL.

Conclusion: The root canals with necrotic pulp showed high levels of LTA and only instrumentation with sodium hypochlorite 2.5% was not enough for its entirely

elimination of the root canals. New studies with other endodontic treatment protocols should be performed for new findings.

**CHARACTERIZATION OF TWO PROTEINS OF LEPTOSPIRA INTERROGANS WITH POTENTIAL ROLE IN HOST-PATHOGEN INTERACTIONS**

A.F. Teixeira<sup>1</sup>, Z.M. Moraes<sup>2</sup>, E.C. Romero<sup>3</sup>, K. Kirchgatter<sup>4</sup>, S.A. Vasconcellos<sup>2</sup>, A.L.T.O. Nascimento<sup>1</sup>

<sup>1</sup>*Centro de Biotecnologia, Instituto Butantan, São Paulo, Brazil*

<sup>2</sup>*Faculdade de Medicina Veterinária, Universidade de São Paulo, São Paulo, Brazil*

<sup>3</sup>*Centro de Bacteriologia, Instituto Adolfo Lutz, São Paulo, Brazil*

<sup>4</sup>*Núcleo de Estudos em Malária, SUCEN/IMT-SP USP, São Paulo, Brazil*

**Background**

Leptospirosis is a worldwide zoonosis regarded as a major public health problem. Measures to control the disease are difficult to implement. The development of new strategies to prevent and control the spread of disease is urgently needed. Accordingly, vaccines emerge as strong candidates to solve the problem. For this reason, currently research has focused to identify conserved antigens that are involved in host-pathogen interactions.

**Objectives**

Evaluate the functional properties of the coding sequence LIC13479 and LIC10050 of *L.interrogans* serovar Copenhageni, identified by bioinformatics as putative outer membrane proteins.

**Methods**

The gene sequences were cloned into the expression vector pAE. Plasmids containing cloned DNA were introduced in *E. coli* strains for protein expression. After purification of the recombinant proteins, mice were immunized for polyclonal antibodies production. Reactivity of the recombinant proteins was evaluated in serum samples of leptospirosis patients and of febrile unrelated diseases. The ability of recombinant proteins to interact with the host by adhering to extracellular matrix proteins or serum components was examined.

**Conclusions**

The coding sequences LIC13479 and LIC10050 were cloned and expressed successfully. Evaluation of the purified recombinant proteins showed that they are capable to stimulate antibody immune response in mice and, in addition, they are recognized by infected human serum samples. Both recombinant proteins exhibited adhesin properties and, in addition, interacted with plasminogen and can generate plasmin in the presence of activator. Our data indicate that these proteins could promote the attachment and contribute to the invasion processes within the hosts

**Background**

STEC-associated HUS was first recognized in Georgia in 2009 following the diagnosis of a cluster of HUS cases in Georgia.

**Objectives**

In this study we genetically characterized two sporadic cases (Case A and B) of HUS syndrome occurred in 2012. Among them was one family case reported (Case B), where four individuals revealed positive on STEC, but only one developed HUS.

**Methods**

Clinical samples were enriched in broth and simultaneously plated on selective agar media. DNA was extracted and tested by two different conventional Multiplex PCR assays for final confirmation of STEC (*stx1*, *stx2*, *eae*, *Ehly*) and detection O104 strain markers (*stx2*, *terD*, *rfbO104*, *fliC H4*). Furthermore, for molecular genotyping Pulsed Field Gel Electrophoresis (PFGE) was applied. Five STEC strains were isolated from both described cases. All revealed positive results by molecular tests on STEC but showed different genetic profiles based on combination of existing

toxigenic markers. Interestingly, it was observed that case A tested positive on all four O104 specific genes. Besides, PFGE typing showed two different genetic profiles as well.

## **Conclusions**

Here described in both HUS cases, a diversity of STEC isolates was detected. However, one of the causative agents was considered to be STEC O104. It is remarkable that two O104 strains were isolated during STEC outbreak in Georgia in 2009 which are genetically related with the strains isolated during STEC outbreak in Germany in 2011. This finding suggests that O104 strain has spread and been circulating for several years in the country.

**ROLE OF IRON IN THE CROSS-TALK BETWEEN THE BIOSYNTHETIC PATHWAYS LEADING TO THE PRODUCTION OF SIDEROPHORES AND COLIBACTIN.**

S. TRONNET<sup>1</sup>, M. PENARY<sup>1</sup>, E. OSWALD<sup>1</sup>, P. MARTIN<sup>1</sup>

<sup>1</sup>The Physiopathology Center of Toulouse-Purpan, INSERM, Toulouse, France

**Background**

The biosynthetic pathways of several siderophores and the genotoxin colibactin require the enzymatic activity of a phosphopantetheinyl transferase (PPTase). We have shown that ClbA, the PPTase associated with the production of colibactin, can also contribute to the production of siderophores, whose production is dependent on the bioavailability of iron in the medium, through the regulation of the expression of EntD, the PPTase previously thought to be the unique PPTase involved in the production of siderophores in *E. coli*.

**Objectives**

We hypothesized that iron could also modulate the production of colibactin through the transcriptional regulation of *clbA*.

**Methods**

Mutant derivatives of *E. coli* were engineered. We investigated transcription of genes involved in the production of colibactin in iron depleted or repleted conditions using qRT-PCR and luciferase reporter gene assay. Quantification of total siderophores was assessed.

**Conclusions**

This study revealed an increased transcription of *clbA* in iron limiting conditions, and a decrease of *clbA* expression in iron supplemented media. Quantification of total siderophores revealed that the increased expression of *clbA* in iron-depleted conditions was associated to an increased synthesis of siderophores. Mutation of *entD* leads to an exacerbation of the induction of *clbA* expression, whereas overexpression of *entD* or *clbA* leads to a repression of *clbA* transcription. Analysis of the region upstream *clbA* shows the presence of two putative Fur-boxes, which could explain its regulation by iron. In conclusion *clbA* is tightly regulated by iron

bioavailability leading to an increased production of siderophores that could explain the high pathogenicity of the strains synthesizing colibactin.

## **VIRULENCE FACTORS OF STREPTOCOCCUS PYOGENES ISOLATED FROM PATIENTS WITH TONSILLOPHARYNGITIS IN KONYA/TURKEY**

H. Turk Dagı<sup>1</sup>, S. Yuksekkaya<sup>2</sup>, T. Seyhan<sup>1</sup>, U. Arslan<sup>1</sup>, D. Findik<sup>1</sup>, I. Tuncer<sup>1</sup>

<sup>1</sup>Medical Microbiology, Selcuk University, Konya, Turkey

<sup>2</sup>Microbiology, Konya Education and Research Hospital, Konya, Turkey

### **Background**

*Streptococcus pyogenes* is an important bacterial pathogen that colonizes the throat and skin of a host and produces a wide variety of virulence factors such as toxins, proteases or DNases.

### **Objectives**

The aim of this study was to investigate the antibiotic resistance and virulence factors (*speA*, *B*, *C*, *G*, *H*, *I*, *J*, *K*, *L*, *M*, *smeZ*, *ssa*, *spd3*, *sdc*, *sdaB*, *sdaD*, *spyCEP*, *scpA*, *mac* and *sic*) of *S. pyogenes* strains isolated from throat cultures of patients with symptomatic tonsillopharyngitis.

### **Methods**

One hundred and fifty *S. pyogenes* isolates were identified by conventional methods and VITEK 2 automated system. Antibiotic susceptibility tests were performed by Kirby-Bauer disk diffusion method as recommended by Clinical and Laboratory Standards Institute. The virulence factors were determined by multiplex PCR.

### **Conclusions**

All of the *S. pyogenes* isolates were susceptible to penicillin G, cefotaxime, ceftriaxone, chloramphenicol, clindamycin, erythromycin, levofloxacin, vancomycin and linezolid. Among streptococcal pyrogenic exotoxin genes the most frequent gene was *speG* (88.0%) following *speC* (59.3%), *smeZ* (46.7%), *ssa* (42.7%), *speA* (33.3%), *speJ* (24.0%), *speK* (18.7%), *speH* (14.0%), *speI* (13.3%), *speL* and *speM* (9.3%). From DNases, proteases and inhibitors *sdaB*, *speB*, *spyCEP*, *scpA* and *mac* were positive in all strains, and *spd3*, *sdc*, *sdaD* and *sic* were carried 64.7%, 36.0%, 24.7%, 2.0% of the isolates respectively. In conclusion, *S. pyogenes* isolates collected from throat cultures of patients with symptomatic tonsillopharyngitis in Konya/Turkey possess high virulence factors, and susceptible to antibiotics.

<sup>3</sup>Division for Bioimaging,  
Institute of Health Biosciences University of Tokushima Graduate School, Tokushima,  
Japan

**Background**

Type 3 secretion system (T3SS), is major virulent factor in over twenty species of Gram-negative bacteria which export bacterial protein (effectors) to host cell to manipulate its cellular function for own's hope. Moreover, T3SS is a prospective useful tool with both experimental and therapeutic applications, including vaccine development.

**Objectives**

Upon analysis of the contribution of the T3SS injectisome and effector involved in this paradigm, it is still unknown that the number and timing of expression of the T3SS injectisome and effectors, and which factor have dominant role during infection are unclear. In the present study, we used fluorescence protein combined with single cell analysis to solve dynamics of the T3SS and effector during infection in *Vibrio parahaemolyticus*.

**Methods**

During infection, Vp1671 (T3SS component) but not the Vp1680 (effector) proteins showed to make spot like localization along the membrane of the cell. Although both percentages of spot positive cells and number of T3SS spots were increased depend on a time of infection, assemblies of the Vp1671 to the T3SS occur prior to increase fluorescence levels of bacterium in early time of infection. Cytotoxicity against the host cells were increased depend on the expression levels of Vp1680 and number of T3SS spot, if it is only one spot.

**Conclusions**

*V. parahaemolyticus* use a combination between a few T3SS injectisome regulated by localization and a lot effector regulated by expression for killing host cells.

**Background**

*Streptococcus agalactiae* causes urinary tract infection (UTI) including asymptomatic bacteriuria (ABU); however, growth of *S. agalactiae* in urine has not been reported and the role of this growth phenotype in human infection is unknown.

**Objectives**

We characterised the ability of different *S. agalactiae* UTI isolates to grow in urine, and defined the molecular mechanism(s) of growth and implications for human ABU.

**Methods**

We used growth assays, competition assays, metabolic phenotype arrays, whole-genome sequencing, and mutation analysis in *S. agalactiae*. We report robust growth of ABU *S. agalactiae* (ABSA) in human urine that was not seen among uropathogenic *S. agalactiae* (UPSA) isolated from patients with acute UTI. In competition assays using a prototype ABSA strain, designated ABSA 1014, and any one of several UPSA strains, we observed markedly superior fitness of ABSA 1014 for urine growth. Phenotype profiling of ABSA 1014 and UPSA 807, isolated from a patient with cystitis, using metabolic arrays revealed specific L-Malic acid catabolism in ABSA 1014 that was absent in UPSA 807. Whole-genome sequencing revealed divergence in malic enzyme-encoding genes between the strains predicted to impact the activity of malate metabolism. Urine growth assays comparing wild-type ABSA and mutants that were functionally inactivated for malate metabolism by disruption of *maeE* or *maeK* demonstrated attenuated growth of the mutants in urine and synthetic human urine containing malic acid.

**Conclusions**

We conclude that some ABU *S. agalactiae* can grow in urine, and this relates in part to malic acid metabolism, which may affect *S. agalactiae* UTI.

## **THE ROLE OF THE MYCOSIN PROTEASE IN TYPE VII SECRETION OF PATHOGENIC MYCOBACTERIA.**

V. van Winden<sup>1</sup>, R. Ummels<sup>1</sup>, W. Bitter<sup>1</sup>, E.N.G. Houben<sup>2</sup>

<sup>1</sup>Medical Microbiology & Infection Control, VU University Medical Center, Amsterdam, Netherlands

<sup>2</sup>Molecular Cell Biology Section Molecular Microbiology, VU University, Amsterdam, Netherlands

### **Background**

A promising new group of novel drug targets for *Mycobacterium tuberculosis* are the type VII secretion (T7S) systems. *M. tuberculosis* has five of these systems, ESX-1 to ESX-5, of which at least three are crucial for the virulence and/or viability of this pathogen. One of the conserved components of T7S systems is mycosin (MycP), a membrane-associated protease that is an essential part of the T7S system. Due to the proteolytic activity of the mycosins they are promising targets for novel drugs against TB.

### **Objectives**

We set out to functionally dissect the role of the mycosin proteases in T7S, by analyzing the phenotype of MycP1 and MycP5 mutants.

### **Methods**

Deletion strains of the mycosins of the ESX-1 and ESX-5 secretion systems were created in *Mycobacterium marinum*. Subsequently, proteolytic inactive versions of MycP1 or MycP5 were introduced in the deletion strains. Functional complementation by these variants was verified by the effect on the secretion by the ESX-1 and ESX-5 systems.

### **Conclusions**

While deletion strains of MycP1 or MycP5 were defective in respectively ESX-1 or ESX-5 dependent secretion, the protease inactive variants were able to mediate secretion by ESX-1 or ESX-5. Thus the proteolytic activity of MycP is not essential for its respective ESX-system dependent secretion. These results indicate a dual function for mycosins, with a proteolytic role in substrate processing and a second, so-far unknown, role in the regulation of the secretion process. We are currently

unravelling this second function in T7S and pinpointing which domain of MycP is involved in this process.

**EFFECT OF DIFFERENT FACTORS ON THE (TWITCHING) MOTILITY OF  
PHOTOBACTERIUM DAMSELAE SUBSP. PISCICIDA.**

B. Vega<sup>1</sup>, J. Bravo<sup>1</sup>, S. Remuzgo-Martínez<sup>2</sup>, J. Ramos-Vivas<sup>2</sup>, F. Acosta<sup>1</sup>

<sup>1</sup>Infectious diseases and fish pathology,

Instituto Universitario de Sanidad Animal Universidad de Las Palmas de Gran Canaria, Arucas, Spain

<sup>2</sup>Servicio de Microbiología,

Hospital Universitario Marqués de Valdecilla Instituto de Investigación Marqués de Valdecilla IDIVAL, Santander Cantabria, Spain

**Background**

*Photobacterium damsela* subsp. *piscicida*, which is the etiological agent of photobacteriosis and affects different species of sea fish, is a non-motile Gram-negative bacterium. Notwithstanding, it is able to move on solid surfaces. Because of the presence of pili-like structures on the bacterial surface, discovered the last year by Remuzgo-Martínez *et al.*, and being associated with twitching motility,

**Objectives**

the objective of this study was to modify some conditions (temperature, pH, concentration of nutrients, salinity, nature of the medium and others) to determine which ones promote motility.

**Methods**

A total of five bacterial strains were tested: C2, 94/99, DI21, PP3 and ATCC 17911. The results of motility assays were obtained after two and three days of inoculation in “twitching motility” medium and statistically analyzed with IBM SPSS Statistics 22.0 program.

**Conclusions**

Lower temperatures, alkaline and acidic environments and lacking salinity had a negative effect on cell motility, while nutrient limitation did not affect the bacterial response. The best twitching motility was observed when *Phdp* was inoculated in medium with 0.2% agar and pH 7.0. Also, interesting results were achieved after scraping petri dishes (surface where the bacteria moved) or the addition of cellular debris of SAF-1 cell line to the medium.

**IDENTIFICATION AND DISTRIBUTION OF A NOVEL 22-KDA OUTER MEMBRANE PROTEIN RELATED TO SHIGA TOXIN-PRODUCING ESCHERICHIA COLI (STEC) STRAINS NEGATIVE FOR LOCUS ENTEROCYTE EFFACEMENT.**

*D. Montero<sup>1</sup>, F. Del Canto<sup>1</sup>, J. Puente<sup>2</sup>, J. Salazar<sup>1</sup>, R. Vidal<sup>1</sup>*

*<sup>1</sup>Programa de Microbiología y Micología,*

*Instituto de Ciencias Biomedicas Facultad de Medicina Universidad de Chile, Santiago, Chile*

*<sup>2</sup>Instituto de Biotecnología, Universidad Nacional Autónoma de México, Cuernavaca, Mexico*

**Background**

STEC strains are etiologic agents of acute diarrhea, bloody diarrhea and hemolytic uremic syndrome (HUS). Associated with STEC outbreaks and HUS, we may observe two main groups of strains, those that in their genomes is encoded the Locus Enterocyte Effacement (LEE-positive), including the serogroups, O157:H7, O26, O103 and O111, and bacteria without this Locus (LEE-negative) which include the serogroups, O113 and O91: H2.

**Objectives**

Describe a novel antigen present in the outer membrane (OM) of a LEE-negative STEC strain.

**Methods**

By western blot and immunoproteomic analysis (2D electrophoresis - MALDI-TOF/TOF) using sera from patients who developed HUS, we were able to identify an immunoreactive protein of 22 kDa with an isoelectric point of 5.0. By mean of bioinformatics tools, we found the encoded gene in the genome of STEC strain O91: H21 B2F1 LEE-negative (Accession: AFDQ01000026.1). Using specific primers, the gene was amplified and its presence was studied in a collection of 170 STEC strains and 11 commensal *E.coli*. Interestingly, the gene was detected only in LEE-negative STEC strains (63%; 32/51). Sequencing of PCR products showed that this gene is highly conserved. Preliminary results suggest that this protein could be involved in bacterial adhesion and hemagglutination.

**Conclusions**

Our results suggest that the identified antigen might be associated only with a subset of LEE-negative STEC strains. Additional studies are needed to determine the role of this protein in STEC pathogenicity.

**LEPTOSPIRA INTERROGANS STIMULATES PLASMINOGEN ACTIVATORS IN VIVO IN EXPERIMENTALLY INFECTED ANIMALS AND NATURALLY ACQUIRED HUMAN LEPTOSPIROSIS.**

M.L. Vieira<sup>1</sup>, Z.M. de Moraes<sup>2</sup>, S.A. Vasconcellos<sup>2</sup>, A.L.T.O. Nascimento<sup>1</sup>

<sup>1</sup>Biotechnology Center, Instituto Butantan, São Paulo, Brazil

<sup>2</sup>Faculdade de Medicina Veterinária e Zootecnia, Universidade de São Paulo, São Paulo, Brazil

**Background**

Leptospirosis is a globally important zoonosis, caused by pathogenic bacteria of genus *Leptospira*. The molecular mechanisms for leptospiral pathogenesis and virulence remain poorly understood. A pathogen invasion, dissemination and host tissue damaging depend on proteolytic enzymes both of the invading organism and of the host. Many pathogens express their own proteases or exploit hosts proteases to activate other protease-dependent cascade systems. We have described that leptospires capture plasminogen (PLG) on the outer surface, which is converted to plasmin (PLA) by exogenous activators. We also showed that leptospires induce the expression of PLG activators by human endothelial cells *in vitro*.

**Objectives**

Here, we further characterized the interactions of *L. interrogans* with human PLG/PLA system *in vivo*.

**Methods**

We studied the stimulation of PLG activators in different time points during leptospirosis in hamsters infected with lethal doses, and in human sera samples from the initial and convalescent phase of the disease.

**Conclusions**

Our data indicate that leptospirosis human patients have increased levels of circulating urokinase-type and tissue-type PLG activators when compared to normal sera, being especially augmented at the early phase of the disease. In the sera of experimentally infected hamsters, increasing levels of PLG activators were observed during the progression of the infection, until euthanasia. Additionally, hamsters' organs extracts similarly showed increased PLG activators activity.

The results presented here further characterize the host response to the *Leptospira* infection, in the light of PLG/PLA system stimulation. Our data strengthen the importance of the fibrinolytic system to the leptospirosis infectious process.

**BINDING OF LEPTOSPIRA INTERROGANS TO HUMAN THROMBIN,  
BIOLOGICAL IMPLICATIONS AND IDENTIFICATION OF POSSIBLE BACTERIAL  
LIGANDS**

L.G. Virgilio Fernandes<sup>1</sup>, Z.M. Moraes<sup>2</sup>, S.A. Vasconcellos<sup>2</sup>, A.L.T.O. Nascimento<sup>1</sup>

<sup>1</sup>*Centro de Biotecnologia, Instituto Butantan, São Paulo, Brazil*

<sup>2</sup>*Faculdade de Medicina Veterinária, USP, São Paulo, Brazil*

**Background**

Leptospirosis is a zoonosis caused by pathogenic spirochete of genus *Leptospira*. The symptoms range from a mild fever to a more complicated, severe form of the disease, called Weil's syndrome. Since the 1980s, the incidence of severe pulmonary hemorrhage caused by *Leptospira* spp. infection has increased. The reasons behind the emergence of this syndrome are not known. Many pathogens can interfere in the coagulation cascade by binding to fibrinogen or by interaction with the enzyme thrombin.

**Objectives**

To characterize the interaction of leptospiral strains to thrombin, analyze the possible biological relevance and select possible proteins that could mediate these interactions.

**Methods**

The interaction of pathogenic (virulent and attenuated) and saprophytic strains with thrombin was performed by ELISA and western blotting. Characterization of the binding sites in thrombin molecule was accessed by co-incubation with different competitors. Reduction in thrombin activity was evaluated by fibrin clot formation assay. Identification of ligands was performed by ELISA by employing a set of recombinant leptospiral proteins.

**Conclusions**

We demonstrated that the pathogenic strains of *Leptospira* display a prominent binding to thrombin, particularly the virulent one. Competition assays indicate that virulent strain binds thrombin via exosite I. Virulent strain could reduce thrombin activity. Although we have identified some proteins that displayed binding to thrombin, none was capable to reduce the enzymatic activity. The interaction of virulent strains of *Leptospira* with the key enzyme of the coagulation cascade, thrombin, might constitute a novel mechanism of virulence, that could help understand the hemorrhagic features of leptospirosis.

## **RELATION BETWEEN THE SEQUENCE TYPE AND THE PROSPECTIVE VIRULENCE OF CRONOBACTER STRAINS**

J. Vlach<sup>1</sup>, B. Javůrková<sup>1</sup>, M. Blažková<sup>1</sup>, L. Karamonová<sup>1</sup>, L. Fukal<sup>1</sup>

<sup>1</sup>Department of biochemistry and microbiology,  
University of chemistry and technology Prague, Prague, Czech Republic

### **Background**

Bacteria from the genus *Cronobacter* are pathogens endangering all age groups, with severe clinical complications especially in neonates and infants. A multilocus sequence typing (MLST) scheme based on 7 housekeeping genes was constructed for *Cronobacter* spp. identification. The method also enables the recognition of sequence types (STs) and clonal complexes (CCs). Although 7 housekeeping genes (*atpD*, *fusA*, *glnS*, *gltB*, *gyrB*, *infB*, and *ppsA*) used for MLST analysis are not virulence related, connection between infections and particular sequence types were described in the literature.

### **Objectives**

The aim of this work was to evaluate the relation between sources of tested strains and their characteristics particularly their sequence type.

### **Methods**

MLST aimed to 7 genes (*atpD*, *fusA*, *glnS*, *gltB*, *gyrB*, *infB*, and *ppsA*) was performed on bacterial collection (over 80 strains). The amplification of genes *gltB* and *gyrB* showed to be difficult, and therefore new sets of primers were designed and tested.

### **Conclusions**

The target genes were sequenced in the majority of tested strains; in the case of incomplete information putative sequence type was determined. The obtained results showed widespread distribution of STs within tested strains. The significant predominance of particular STs was not determined in tested strains. Perhaps, the amount of tested strains was not representative enough; the ST relation to virulence will be further studied together with other possible factors.

This work was supported by the Czech Grant Agency (13-23509S) and Specific University Research (MSMT No. /2015).

<sup>4</sup>Malopolska Centre of Biotechnology, Jagiellonian University, Krakow, Poland

<sup>5</sup>Department of Microbiology, Jagiellonian University, Krakow, Poland

### **Background**

*Staphylococcus aureus* is an opportunistic pathogen of humans and animals. Our studies have revealed a link between the genotype of poultry-isolated *S. aureus* strains and their virulence in chicken embryo but not nematode model, what may suggest the existence of factors responsible for host preference and virulence.

### **Objectives**

Here we compare genomes and extracellular proteomes of four virulent and four non-virulent *S. aureus* strains in chicken embryo model. The open reading frames translation products for all strains were taken together and clustered according to the similarity level of 80%. Over three thousands clusters were obtained with only around 40% of clusters containing proteins with identical sequence across all strains. However, within the virulent and non-virulent group around 80% and 54% of clusters ORFs encoded identical proteins, respectively. The exoproteomes were highly heterogeneous irrespective virulence, however we were able to point alpha-hemolysin and bifunctional autolysin as indicators of virulence whereas glutamylendopeptidase as potential virulence attenuator.

### **Methods**

The genomes were obtained using MiSeq Illumina sequencer and assembled with MIRA and CLC Main Workbench software. Extracellular proteins were precipitated, labeled with fluorescent dyes and subjected to two-dimensional difference gel electrophoresis in pairs virulent *versus* non-virulent. Differentiating protein spots were subjected to mass spectrometry analysis.

### **Conclusions**

Deep sequencing confirmed genetic dissimilarity of virulent and non-virulent strains which finds its reflection in extracellular proteome. However, proteomics also points transcriptional and translational events as modulators of *S. aureus* virulence.

The study was supported by the grant UMO-2012/07/D/NZ2/04282 (to B.W.) from National Science Centre, Poland.

## **ADHESINS FROM YERSINIA RUCKERI**

A. Wróbel<sup>1</sup>, D. Linke<sup>1</sup>

<sup>1</sup>Department of Biosciences, University of Oslo, Oslo, Norway

### **Background**

*Yersinia ruckeri* is a Gram-negative bacterium pathogen responsible for enteric redmouth disease (ERM). *Yersinia ruckeri* infections cause significant economic losses in salmonid aquaculture. ERM can be effectively controlled by antibiotic treatment and by application of whole cell based vaccines. Nevertheless, ERM outbreaks are still observed. More recently, vaccine resistant isolates caused disease throughout Europe. Research into the pathogenicity of *Yersinia ruckeri* is limited. Much more is known about the host-pathogen interaction of the three *Yersinia* species pathogenic to humans.

The group of proteins, that mediate the host-pathogen interaction comprise adhesins anchored in the bacterial outer membrane. They are essential for infection as they possess the ability to bind a variety of host molecules such as collagen, fibronectin, laminin,  $\beta 1$  integrins.

### **Objectives**

The aim of my research is to establish a fish infection model – zebrafish to understand the molecular mechanisms of adhesion and to identify adhesins of interest and their cellular receptors in order to assess their function in pathogenesis.

### **Methods**

To examine whether adhesins of interest are involved in *Yersinia ruckeri* virulence, fish cell line and in vivo system (zebrafish embryos) will be used and optimise. Fluorescence microscopy will allow to visualize infections to assess the role of virulence genes. Infection of colour- fluorescence bacteria will be essential to follow the infection.

### **Conclusions**

Understanding the molecular mechanisms of adhesion in fish, might prevent progression of infections. Moreover, the knowledge gained could help in developing new antimicrobials that could directly act as vaccines against bacterial fish diseases.

**MOLECULAR CHARACTERISTICS OF BRUCELLA ABORTUS MUTANTS  
GENERATED WITH EZ-TN5™ PMOD™-3 TRANSPOSON**

Y.B. Im<sup>1</sup>, W.B. Park<sup>1</sup>, M.K. Shin<sup>1</sup>, M. Jung<sup>1</sup>, H.S. Yoo<sup>1</sup>

<sup>1</sup>Department of Infectious Diseases,

College of Veterinary Medicine Seoul National University, Seoul, Korea

**Background**

*Brucella abortus* is a well-known intracellular pathogen. Underlying mechanisms of the bacterial infection is very complicated to understand the pathogenesis even though most of clues have been solved. Therefore, prevention and control of the *B. abortus* infection is still problematic in animal and human. So, several methods including random mutation have been used to understand the mechanisms and find out the solution in control and prevention of the infection. Regardless the trials, the doors to be opened are still locked in understanding of the mechanism.

**Objectives**

To understand the underlying mechanism of *B. abortus* infection, mutants were generated with a transposon and function of the disrupted genes were revealed.

**Methods**

Mutants of *B. abortus* were generated by random insertion of a transposon, Ez-Tn5™ pMOD™-3 <R6K<sub>ori</sub>/MCS> into chromosome. Molecular characteristics of the mutants were investigated using PFGE, Southern blot and sequencing of the genes.

**Conclusions**

*B. abortus* mutants were generated and insertion of the transposon was confirmed by Southern blot analysis with the transposon as a probe after PFGE of chromosome. Both sides of insert in the chromosome were sequenced and the location of interrupted genes were identified in chromosome. Using sequencing information, twenty-eight genes were identified from the mutants by comparison with wild type of the bacteria. Also, function of the genes were revealed. This work was supported by NRF (No. 2014R1A2A2A01007291).

**CYTOKINE EXPRESSION PROFILE IN RAW 264.7 CELLS STIMULATED WITH BRUCELLA ABORTUS MUTANTS**

W.B. Park<sup>1</sup>, Y.B. Im<sup>1</sup>, M.K. Shin<sup>1</sup>, M. Jung<sup>1</sup>, H.S. Yoo<sup>1</sup>

<sup>1</sup>Department of Infectious Diseases,

College of Veterinary Medicine Seoul National University, Seoul, Korea

**Background**

*Brucella abortus* have been known as an important intracellular, zoonotic pathogen. Intense immune responses are induced in animals by the bacterial infection. Cytokine has key roles in activation of innate immunity and acquired immunity. Precious roles of cellular components of *B. abortus* infection have been remaining to be solved even though involvements of immune cells in activation of acquired immunity are already known. On the basis of current understanding, production profiles of inflammation cytokines such as NO, IL-1 $\beta$ , IL-4, IL-12 and IFN- $\gamma$ , were compared with *Brucella* mutants. Moreover, it might be given a key to find immune system, pathological pathways, and mechanism.

**Objectives**

To understand the roles of cellular components of *B. abortus* in immune cells, production profiles of cytokines were investigated in a mouse macrophage cells, RAW264.7 cells after stimulation with *B. abortus* mutants.

**Methods**

RAW 264.7, murine macrophages, cells were stimulated with mutants of *B. abortus*. Culture supernatants were collected from RAW 264.7 cells after stimulation with *B. abortus* mutants at different time intervals. Amounts of cytokine such as NO, IL-1 $\beta$ , IL-4, IL-12 and IFN- $\gamma$ , were quantified with ELISA.

**Conclusions**

Inflammatory cytokines were produced from Raw 264.7, murine macrophage, cells after stimulation with the *B. abortus* mutants. After then, production levels of inflammatory cytokines such as NO, IL-1 $\beta$ , IL-4, IL-12 and IFN- $\gamma$ , were measured. The patterns of the cytokine productions will be presented. This work supported by NRF (No.2014R1A2A201007291) and IPET112012-03-1-HD020.

<sup>3</sup>Microorganisms Biology Research Unit (URBM), University of Namur, Namur,  
Belgium

### **Background**

*Brucella* pathogens proliferate within several eukaryotic cells. Cumulative evidence indicates that adhesion of *Brucella* to host cells is an important step to establish infection. We have shown that the unipolar monomeric autotransporter BmaC is involved in the adhesion of *Brucella suis* to host cells through binding to cell-associated fibronectin.

### **Objectives**

Genome analysis shows that the *B. suis* genome encodes two trimeric autotransporters (BtaE and BtaF) and two additional monomeric autotransporters (BmaA and BmaB). The aim of this work was to explore the roles of these proteins in the interaction of *Brucella* with the host.

### **Methods**

Clean deletion mutants were analyzed by in vitro binding assays and in vivo using the mouse model. Adhesin localization was analyzed by immunofluorescence.

### **Conclusions**

BtaE was involved in the binding of *B. suis* to hyaluronic acid and fibronectin while BtaF may contribute to the binding to several ligands. Both the  $\Delta btaE$  and  $\Delta btaF$  mutants showed a reduction in the attachment to epithelial cells and were attenuated in mice. Similar to BmaC, BtaE and BtaF were detected in a low proportion of bacteria but in all cases at one particular pole. A remarkable variability in the number of motifs of autotransporter orthologues from different *Brucella* species was observed.

Furthermore, while both trimeric autotransporters might be functional in all *Brucella* species, pseudogenization occurred in *bmaA* and *bmaB* orthologues. In particular, BmaA would not be functional in *Brucella abortus* while it is predicted to be functional in *B. suis* and *B. melitensis*. Thus, functional autotransporters may contribute to host preference.
